Photography has so many attractive applications to one thing and the other at the present time that it has too much the effect of distracting the attention of some of the most important questions which it raises, such as the chemical and art knowledge which is in its power to revolutionize. Yes, we photographers can honestly say that now, especially to those who approach photography as a mere mechanical operation, and say that we need not possess taste, imagination, or even a knowledge of the rudimentary elements of pictorial art; some will say no mechanical process can long supersede the living agency of man's mind, and that photography is and never can be anything more than a servant of servants; and they will use arguments neither novel nor ingenious to say that photography cannot maintain the positions in which we admirers of the wonderful processes connected with our art are placing it. Now these remarks do not make the slightest impression on genuine practical workers; it is like water on a duck's back to me, and if I have anything to carry out I generally put wool in my ears until it is finished, or, at least, until the difficult part is over. I admit we lose a lot of thoroughness, or what ought to be done thoroughly, through the excitement produced by the marvels of the science, such as the want of taste in the point of view selected to take a picture, and the noticing of curious phenomena which crop up during our laboratory experiments, but as long as the world lasts we shall always have that; but what I mean is, for us to look at the progress year by year photography is making into everything. Chemists taught us at first, it will be soon, if we work earnestly, the reverse. We shall teach the chemist, for the more I consider the chemical question in relation to photography, the more strongly it forces itself to my notice, and I look forward to our occupying much larger space in the domain of chemical inquiry than is the case at present. The relation of light and heat and electricity is having plenty of fun with photography at present, but they must mind photography does not have some fun with them by and-by, and if photography is not a relation it will find out what relation one is to the other. There is plenty of food for photography to digest in the chemical rays of the electric spark causing the combination of oxygen, also measuring numerically the quantity of light absorbed in different chemical actions. It seems hardly possible not to indulge a hope that the pursuit of photography in chemical inquiry may, by degrees, conduct us to a mechanical theory of chemical action itself; so far for the field of photography in the way where day by day we can go on improving. Look at the grand lenses made now, and the results we obtain through them; but we still want magnitude, and the beauties of perspective not diminished. There is a good field for lenses. We photographers should not be too frightened of getting the sun into our lens, and turn our back on our best friend, and lose all the cross shadows which give the stereoscopic effect to a picture. I have found the most pleasing effect produced where the sun is shining towards the lens. Now, as to novelties, I am going to show you a few to-night. Firstly, my opal cards, which I will demonstrate; secondly, those few ivory pictures, upon which I should like to hear your candid opinion, therefore I will say nothing more about them, but pass them to you; thirdly, I have brought this scroll, as I am anxious to know if any one can tell as how the ornamental border is done. It is not done in England; I have never seen anything so fine produced here. Still, we are not beaten in everything, not even by our American cousins, for here is a camera with one movement constructed to take three or four pictures a second by simply turning a handle, a thing which has never been accomplished before.

The CHAIRMAN invited discussion and questions upon it.

Mr. W. E. DEBENHAM inquired what was the complaint which Mr. Greene had to make against the perspective yielded by photographic lenses.

Mr. GREENE said that near objects were rendered disproportionately large,

and added that he had particularly noticed this when taking the Convention group, and trying to have a figure in the foreground; moreover, he could not get foreground and middle distance in focus at the same time.

Mr. DEBENHAM maintained that the perspective given by the ordinary non-distorting photographic lenses was absolutely correct, and represented objects in the position in which they would appear on a sheet of glass held in front of the eye of an observer placed in the same position as the camera.

Messrs. A. H. HADDON, COOKE, and ATKIN endorsed this view.

With regard to a remark of Mr. Greene's referring to an attempt to photograph a positive direct in the camera, the CHAIRMAN said that on one occasion he had added some solution of ferricyanide of potassium to the developer in mistake for pyro; the image on the plate disappeared, and on washing and developing with a fresh solution a positive instead of a negative image resulted.

Mr. HADDON inquired whether the opal cards upon which Mr. Greene made his prints were absolutely waterproof.

Mr. GREENE replied that they were so for a short time.

Mr. HADDON said that there was a great want of a really impervious varnish for many purposes in the arts.

Mr. GREENE said that he had had several applications for the varnish that he used for different purposes, one being for making water-tight wrappers for tea.

Mr. COOKE wished to know how long washing the cards would bear.

Mr. GREENE replied: Three minutes. A great advantage of these cards was that two or three dozen prints could be delivered the same day. Sepia tones could be obtained by modifying the developer. A print illustrating this statement was handed round. In preparing the cards it had been found that the ink with which in some cases they had been printed had caused a plentiful crop of spots and fog, reminding one of the messes on a wet collodion plate.

Mr. F. W. BRIDGE inquired whether it would be possible to obtain this waterproof material for photographers to apply to their own cards.

Mr. GREENE replied that in time that would be arranged.

The CHAIRMAN inquired whether the prints on celluloid would stand fairly rough usage.

Mr. GREENE: Yes.

Mr. J. J. BRIGHNSHAW inquired whether the celluloid was coated with emulsion in the same manner as the cards.

Mr. GREENE said that it was, but in order to overcome the repulsion of the celluloid it was first treated with wood naphtha.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

SEPTEMBER 3.—Rev. E. Healy in the chair.

Mr. P. SPENCER, who had just returned from India, showed views of buildings, balloon ascents, groups of Indians, &c.

The Chairman, and also Mr. W. Bishop, showed views taken by them during the summer.

Mr. SPENCER stated that an unfortunate accident happened to his lens while travelling over rough roads in India, one combination having been reduced to powder by the vibration. He supposed that the glass must have been a little loose in its cell, but advised members to carry their lenses in such a way as to avoid all risk.

The CHAIRMAN advised the use of spirits of turpentine for reducing halation in negatives, as more powerful than methylated spirits.

The next meeting will be on September 17, at eight p.m.; the subject will be *Holiday Experiences*. Members and visitors are invited to bring prints and state experiences.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

SEPTEMBER 6.—The President (Mr. F. W. Edwards) in the chair.

Seven members were elected and one proposed.

Further contributions of lantern slides were made by Messrs. Dowling, Gardner, and Kelly.

A large number of prints and negatives were handed round for inspection, amongst them some fine 24 x 18 platinotypes by the President.

Next meeting on Friday, October 5, at 76, Peckham-rye. Paper on *Lenses* by the President.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

AUGUST 29.—Mr. A. W. Beer in the chair.

The minutes of the previous meeting were read.

The following gentlemen were elected:—Messrs. J. W. Smith, William Whiteside, Walter De Wolf, and C. Mortimer Booth.

Reports were given upon the excursions recently held. That to Tonge, Boscolob, and Lillishall Abbey consisted of a small party, who enjoyed fine weather and had a pleasant outing. Twenty exposures were made with fair results. The excursion to Pont-y-Pant, on July 22, was held under less favourable weather. The party consisted of six, and fifty exposures were made. The excursion to Eastham Lake, on August 10, was affected by St. Swithin more or less, indifferent weather prevailing; however, a pleasant day was passed. Seventeen took part in the excursion, and sixty exposures were made. Mr. Forrest showed prints taken on the occasion. The excursion to Raby Mere, on Saturday, August 24, consisted of twelve; sixty plates were exposed. The weather was mixed, and, owing to the heavy rain prevailing for the week previous, the lanes gave some trouble, causing many divergencies to avoid the mud, &c.; however, some very good subjects had been met with, and the day was pleasantly spent.

Mr. H. WILKINSON then read his paper on *The Intelligent Use of the Detective Camera*, which proved of great interest.

A short discussion followed, in which Messrs. Illingworth, Pearson, and Lange took part.

The PRESIDENT was of opinion that Kershaw's shutter was quite quick enough, as seen by Mr. Wilkinson's prints, which were of a very good order,

large in quantity, and artistic results being secured. He considered it mattered very little how the camera was held so long as the results were satisfactory, and thought the discussion would be useful in throwing minor lights on the subject. We know what an exceptional experience it is to obtain a large proportion of good results from hand camera work, therefore any practical notes for the more successful working of the shutter box should be worthy of very careful digestion and assimilation.

A cordial vote of thanks was then passed to Mr. Wilkinson.

Messrs. Earp & Swinden's detective camera was then exhibited, the principal features being—twenty plates carried, or any less number; plates changed instantly by a single action, and without opening the camera or attracting attention; compact and of small dimensions; an intermediate shutter which cuts off all light from the plates is provided; has a door at the side, so that exposed plates may be removed when required; no carriers used, each plate being backed with non-actinic paper; provision is made for vertical as well as horizontal pictures; it may be used on the tripod for ordinary or slow exposures; has a rising front; the lens carrier is moved by rack and pinion worked underneath, so as to focus for various distances; it is provided with a view finder and Kershaw shutter.

Mr. H. J. NICHOLLS explained a recent improvement he had applied to his hand camera, by which the "cannon-like optical hole" was covered by a metal plate made to hold an address card, which, upon being moved to one side, wound up the shutter. Referring to Messrs. Earp & Swinden's camera, he thought it the *ne plus ultra* of apparatus for detective work, and most workers would find their *impedimenta* reduced to the smallest and most portable style; as an expensive camera it would be difficult to surpass. With his own camera he had been enabled to take very good groups, &c., where he would not like to venture a shot with an ordinary hand camera.

The PRESIDENT thought the camera introduced and invented by Mr. Nicholls would meet with much acceptance, and was sure the exhibits before them had been instructive and interesting.

A cordial vote of thanks was unanimously passed.

Referring to eikonogen as a developer, the PRESIDENT said, By the kind attention of our Hon. Secretary, I have been enabled to give a practical test to the new developing agent prepared by Dr. Andresen, of Berlin. This material, of a pinky dead colour, and of an earthy character, is, without doubt, of the quinol group, but its exact component parts are not revealed. The formula supplied to me I made up, with a slight but useful alteration, and is as follows:—

No. 1.

Soda sulphite	14 ounces, 30 grains.
Eikonogen	3 drachms.
Ammonium bromide	20 grains.
Water	26½ ounces.

No. 2.

Carbonate of soda (washing soda)	3 ounces, 5 drachms.
Water	26½ ounces.

You must mix and use these two solutions with discrimination. For instance, the published instructions say three parts of No. 1 to one part of No. 2; now, I have found very few occasions when that was the best proportion to use the developer. I commenced by developing lantern slides by contact, and found that the full strength of developer was only suitable for strong negatives and correct exposure, and that *one-third* less of No. 2 (soda) gave better results. At the same time, except a slight decrease of time required for development, I could not find that it had any advantage whatever over hydroquinone. As a matter of fact, it seems to me to have certain disadvantages compared with that reagent. Hydroquinone is as near an approach as we are likely to obtain to an automatic developer. If the subject is not over-exposed one may almost drop the plate in the hydroquinone developer and leave it alone until it is completely developed. Not so eikonogen, which requires as careful watching and constant rocking as our old friend pyro. The development certainly proceeds with much greater rapidity, but I do not consider that any particular advantage. I pass round for your inspection four transparencies developed by the eikonogen formula. Some I intensified to test the receptiveness of the film, and found that it took Werner's intensifier very well. Turning to negatives, I found I had three undeveloped 10×8 plates, and, as it happened, they were by three different makers, viz., Thomas's, Kingston Special, and Britannia, all landscape, and with normally correct exposures. These three were all developed with the same three ounces of developer, and they might be all from the same batch of plates. I must mention that my system of printing requires *thin* negatives, so that these specimen plates are not by any means as dense as the developer would give. The developer was in this case diluted by two-thirds of an ounce of water to three ounces of the mixed developer, and I think I added a few drops of a ten per cent. solution of bromide of potassium. There seems to be great reducing power in the developer, and when an accurate knowledge of the best restraining medium to use with it is obtained we may find it a capable and useful developer for general all-round work.

Samples of eikonogen were distributed for members to experiment and report on by Mr. Paul Lange, and he also exhibited Tylar's lantern mask cutter with a revolving table, as made by F. Eaton, 31, Highfield, Rock Ferry.

LEWES PHOTOGRAPHIC SOCIETY.

SEPTEMBER 3.—Annual meeting.—The President in the chair.

Mr. R. C. Bennett was elected a member.

The HON. SECRETARY then read the report of the Council for the past year.

The Treasurer's report showed a balance in hand of 27. 0s. 1d.

The Society at present numbers thirty-eight members.

The Council wish to thank the press, local and otherwise, for the kind notices of the Society meetings.

The balance sheet was then read.

All the retiring officers were re-elected with the exception of Mr. A. N. C. Corder, who had resigned the Committee in consequence of business engagements. Mr. G. J. Wightman was elected to fill the vacancy.

Several slight alterations were made in the rules.

A letter was read from the Hon. Secretary of the Brighton Society, extending an invitation to the Lewes Society to join them in an excursion to Shoreham on the 14th instant. The invitation was cordially accepted.

An excursion to Groombridge was also arranged for the 28th instant.

DARLINGTON PHOTOGRAPHIC SOCIETY.

SEPTEMBER 9.—Mr. W. F. K. Stock in the chair.

In consequence of many of the members not having returned from their holidays, it was thought advisable to postpone the show of "holiday work" until the next meeting, to be held October 14.

It was decided to hold a competitive exhibition in February, 1890.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 4.—Annual meeting.—Dr. Anderson (Vice-President) in the chair.

Messrs. Fittes (Architect) and Murray (High School) were elected honorary members, and Messrs. J. Wilson and J. Duncan ordinary members.

Dr. ANDERSON, in his address, gave a *resumé* of the work of the past year, and noted particularly that the best attendance was always when practical work was to be done; and, therefore, suggested that that, with exhibitions of work and lantern slides, should form a good part of the ordinary meetings.

The Association is in a flourishing state, numbering now over thirty members. The Treasurer's report showed an income of 9*l.* 16*s.* 9*d.*, and a balance of 4*s.* 5*d.* in favour of the Association.

The following office-bearers were then elected for the ensuing year:—*President*: Mr. William Shaw Adamson, Careston Castle.—*Vice-Presidents*: Dr. Anderson and R. A. Scott, M.A.—*Committee*: Baillie Lawrence and Messrs. Mackie and Braid.—*Curator*: Mr. J. C. Middleton.—*Treasurer*: Mr. William Stewart.—*Secretary*: Mr. James D. Ross, 13, Park-road.

Correspondence.

Correspondents should never write on both sides of the paper.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—Mr. Graham Balfour is kind enough to think he has got me on the horns of a dilemma. He says:—"Either Mr. Robinson is asking to see Dr. Emerson's pictures, which he has seen himself any time for the last six years at the Pall Mall Exhibitions and in illustrated volumes, or he has been criticising and condemning the work of a photographer without taking the trouble to qualify himself for his self-imposed task by examining the work in question."

I do not believe that Mr. Balfour would be consciously discourteous, but there is a grave suspicion of the unconscious variety in this sentence, for it suggests that I have been criticising without seeing, which would be a literary dishonesty. I think I have seen nearly all that Dr. Emerson has published or exhibited, but that is not the point, and is only mentioned to show I am not the Rip van Winkle Mr. Balfour calls me. This is the important point. I have never, as far as I am aware, criticised Dr. Emerson's work (by which, I presume, is meant pictures) except once, when I said that his *Poacher* was one of the best pictures in the Exhibition. I have admired many of Dr. Emerson's pictures, but the best, in my eyes, did not always illustrate his theories.

It is not, therefore, for my own gratification only that I suggested that the naturalistics should show us the results of their theories, but that photographers generally may have an opportunity of seeing them, and perhaps becoming converted. I don't think judges would be required, but I should not object to Mr. Graham's suggestion of the last three A.R.A.'s.

Mr. Balfour makes a comparison of those who employ dressed-up models, combination printing, &c., and those who study long and patiently out in the country. There is a fallacy here which the naturalistics persistently use. I can assure Mr. Balfour that those who practice photography as I do, think as much of "long, patient study in the country" as do the naturalistics, and could, possibly, pass as stiff an examination on the phenomena of nature as any of them. Nature is not the copyright of any class or school.

There is one question I should really like Mr. Balfour to answer. Where does he find that I have ever "assumed that all who differed from him had been swallowed up?" This he gives as the cause of his letters. I did not know that I claimed to be the possessor of the voracity of Aaron's rod.—I am, yours, &c.,

H. P. ROBINSON.

To the Editor.

SIR,—Mr. Robinson, in recent articles and chapters, has, in his good-humoured, confident manner, made such distinct invitation to those of a naturalistic way of thinking to declare themselves, that it was to be expected he would reply to so fully adequate an opponent as Mr. Balfour. This he declines to do on the ground of having fully discussed the subject already. Mr. Robinson is, perhaps, surprised to find that there are any naturalistics at all in photography, and that these ungrateful upstarts do

not read his books in the hope of gaining any instruction, but only to controvert them and stem their evil influence.

Now, instead of having fully discussed the subject, in the opinion of some of those who think they understand the meaning of Naturalism in art, and believe in it, Mr. Robinson has made no effort to meet the actual attacks which it makes upon his teaching and practice. He has either quite misjudged the real force and meaning of Naturalism, or has intentionally limited his attention to one feature of its principles, in which he was certain of sympathy from the million, whose one idea is sharpness everywhere, at all costs. Mr. Robinson appears to hold that Naturalism is defined by the word *fuzziness*, and by going somewhat unfairly for this evil of his own invention, he succeeds easily, with his characteristic mixture of smile and sneer, in exciting the ridicule of the *unnaturalists*. At another time, however, some suspicion is aroused that he is hoodwinking his own supporters, for, in excusing himself to those of an artistic turn, he claims that he has always fought for a "moderate amount of focus" only, and for a "certain amount of softness." Now, were the whole battle fought on this one point, Mr. Robinson would, from his practice, have to disclaim the great body of topographers who support him, for they do not want even this amount of "softness."

Mr. Robinson has tried to make Naturalism a bugbear to photographers, but the impartial student will find there is nothing very terrible in it, and that as far as mere focus goes, even Mr. Robinson himself (presumably under compulsion of his lenses) might be included within the sacred pale. Unfortunately, all hope of Mr. Robinson's regeneration is denied his naturalistic friends by his attitude on other points, in which he is diametrically opposed to naturalistic principles. On these points Mr. Robinson is judiciously silent, for, if he brought into prominence a defence of combination printing, and of dressing ladies as country girls and fisher lasses for his pictures, he would find even his quondam retainers, the topographers, alienated. It is not in man, even in *5-ft* man, to overlook the unnaturalness of joinings in photographic pictures, and the too visible drawing-room drapery air about attractive ladies playing at haymakers and fishwives. Naturalism does not stand or fall upon a question of how much or how little softness of focus is admissible, but it certainly is diametrically opposed in its view to the much worship of register marks, and to all unnaturalism in figures and their attire. Its creed is, *Truth, and the best of everything*. This differentiates it from the ordinary school, which, instead of considering exclusively the actual colouring, harmonies, tone, feeling, character of a subject, imparts what is termed imagination into the work, and treats much of the colouring, drawing, and selection from a consideration of theories or conventional ideas deduced from an analysis of the works of former successful painters.

As regards the discussion concerning the manner in which the eye actually sees a landscape picture, it would appear that in embarking on this scientific enterprise Mr. Robinson has got upon uncongenial ground. It is not so much a matter of what the eye can do if the mind wish it, but what, under certain circumstances, it actually does and is desired to do by the artist. Every one will readily admit that whilst the eye is fixed on a centre of absorbing interest the rest is only felt, that is, is out of focus; and equally readily it may be admitted that the eye can range, though but slowly, over a landscape so as to bring every part into fair focus, even to any number of degrees. But this is exactly where the whole point comes in. The eye can do so, but it does not. In a great number—the majority—of pictures the interest is concentrated on some specially beautiful or strong incident, and in such a picture, whilst it is quite true that the eye could pass successively from one plane to another, it does not do so, nor does the artist wish it to do so. There is the subject, and that is the supreme moment to fix it. If there be nothing of special beauty or importance in a scene, the eye ranges in a general way over it, or makes in succession a few points of rest for itself, a state of things which no one but a combiner of several negatives could hope, or would wish, to imitate in pictures.

As a matter of fact, Mr. Robinson greatly over-estimates the rapidity with which the eye accommodates its focus to several planes successively, as any one can test for himself.

It would occupy too much space to go further into the question and support the contention that even the principal centre of interest of a picture is best not rendered with all its detail, but the man who does not see and feel this after some study is, in my opinion, lost to the best that is in art.

There are one or two minor personal points in Mr. Robinson's letter which I cannot resist the temptation to refer to. In replying to Mr. Balfour, he declines to argue further in words, and calls for works, and a competition between himself and the naturalists, as though he himself and the public had never yet seen the practical outcome of naturalistic principles. Doubtless Mr. Robinson has a charming picture in store for the Pall Mall Exhibition which he is justified in feeling some exultation over, and which we shall all be interested to see—and dissect; but I cannot help thinking that this part of his letter would have been better devoted to a defence against Mr. Balfour's able attack of his peculiar and astonishing doctrine that the distinctive quality of photography is definition.

Mr. Robinson's reference to the fact of his being on the Hanging Committee at Pall Mall seems still more difficult to account for. Surely he does not imagine that the Hanging Committee would, under anybody's influence, spoil the best arrangement of the pictures for the purpose of

facilitating the decision of a squabble between rival schools of photographers.

Trusting, sir, that Mr. Robinson will feel able also to play me off against Dr. Emerson for my "fairness and good temper," as in Mr. Balfour's case,—I am, yours, &c.,
Camera Club, 10th Sept.
GEORGE DAVISON.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the Editor.

Sir,—Kindly permit me to remind intending exhibitors that Wednesday next, September 18, is the last day for receiving "packing cases" from the country by our agent, Mr. Bourlet, 17, Nassau-street, Middlesex Hospital; and also that the same day is the *only one* for receiving pictures and apparatus at the Gallery. Any further information can be obtained from me.—I am, yours, &c.,
Edwin Cocking, Assistant Secretary.
5a, Pall-mall East, S.W.

THE CELESTIAL SOURCE OF PHOTOGRAPHIC CHEMICALS.

To the Editor.

Sir,—Doubtless many of your readers would like to know from what *raw material* "eikonogen" is made. May be, the enclosed cutting will throw some light upon the matter.—We are, yours, &c.,
22 and 23, Soho-square, London, W.
Messrs. MARION & Co.

"From these pages" a good deal may be gathered touching the strange and silly superstitions of the Chinese, but of all singular hallucinations one can scarcely conceive anything more senseless than the rooted conviction which many of these Celestials entertain that photographic chemicals are made out of the eyes of deceased children, arguing, as they do, that if they were not, how could a little water and white powder see to make such correct pictures, especially when they are shut up in the dark in a little black box. Whenever children are missing from a family, the common rumour runs that they have been made away with by the Europeans for photographic purposes."

THE PHOTOGRAPHIC CONVENTION.

To the Editor.

Sir,—I should not have thought it worth while to reply to the remarks in Mr. Peasgood's letter published in your contemporary, had not Mr. L. E. Morgan referred to the matter. At the outset, I must question Mr. Peasgood's right to set himself up as an authority in respect to the position of the Convention, inasmuch as he has in no way been officially connected with it since its commencement, beyond the appointment last year as one of the auditors, a position that evidently caused him much perturbation.

A statement of one or two facts in connexion with Mr. Peasgood's attitude towards the Convention will give some idea of the sincerity of his motives, and the dependence that may be placed upon them. At the annual meeting last year at Birmingham the proposition for holding the Convention in London was stoutly opposed by Mr. Peasgood; finding, however, the tide of opinion too strong for him, he with a deliberate change of front actually seconded the resolution before the meeting, at the same time expressing himself in favour of the same. The London meeting is scarcely over when another right-about-face movement is perceived in the avowed hostility to the Association evinced in his letter referred to. Comment on such erratic conduct is superfluous.

Turning now to a more congenial subject, I am able to assure your correspondent, Mr. L. E. Morgan, that far from being in an unsatisfactory position, the Convention has made steady progress since its foundation, each meeting resulting in an increased muster-roll, and this in spite of interested detractors, who find the movement in conflict with schemes of their own. That the Convention has done good work since its foundation is an admitted fact. The many able and valuable papers that have been read at the Convention meetings would alone be a justification for its formation. Thoroughly representative in character—its members being drawn from the whole of the United Kingdom—it is competent to discuss questions that no local society of itself is able to take up, a want much felt, and a desideratum that should entitle the Association to the support of all interested in photography. While, from a social point of view, it is unique in the photographic world, as a means to a pleasant periodical reunion of all ranks of the fraternity and the establishment of firm friendships—not the least of the many enjoyable features associated with it.

With regard to the remarks under the heading *Convention Notes*, in THE BRITISH JOURNAL published last week, I must point out that the second paragraph is scarcely correct. The fact that the Convention was not opened by either of the Patrons was certainly not due to indifference on their part, but from an unfortunate choice of the time the Convention was held. In every instance save one, notification of the inability to be present through absence from London was accompanied with the heartiest good wishes for the success of the meeting, and a regret that, from the causes stated above, the writer was unable to take part in the proceedings.

The foot-note that you refer to, that appeared in conjunction with Mr. Pringle's letter in the *Photographic News*, calls for some explanation from me. Printed slips of the papers to be read were distributed each evening to the whole of the members and the press assembled, the editor of the *News*, of course, included, to whom, on the evening in question, I notified

* *The Land of the Dragon*. By William Spencer Percival. (From Morning Post.)

the situation as regarding the publishing of the papers, leaving him at liberty to take his own course in the matter. You will remember that prior to the meeting, to prevent your *Journal* having an undue advantage, by reason of your having the articles in type, you undertook to copyright all papers for one week. It is now known to me that that was impracticable.—I am, yours, &c., J. J. BRIGGS, *Hon. Sec.*
128, Southwark-street, London, September 9, 1889.

Answers to Correspondents.

- J. F. BLACKMORE.—Cold bath process.
F. R. M. S.—You are quite right. Such re-shashes only appear through inadvertence.
F. J. SKILL.—Having first brought the pieces of the negative in close contact, make a transparency and retouch out the marks of junction; then from this make another negative.
F. W. MUXEY.—1. A very full exposure is required, and the development should not be carried too far.—2. Yes.—3. The action of light causes a reduction of the silver.
DOUGLAS DITT.—From the appearance of the spots, they are more likely to be caused by something external—the covering tissue paper, for instance—than by want of care in the fixing and washing. One of the most convenient tests for hyposulphite of soda is iodide of starch.
G. BRADSHAW.—The “carbon” used in the manufacture of carbon tissue is usually “vegetable black.” In the finest tissues a medium quality of Indian ink is generally employed.
SEPTIM.—We cannot express an opinion as to the purity of the mounts without making an analysis. Better place them in the hands of an analytical chemist, who will report upon them after examination.
ANXIOUS LEARNER.—1. Your work is so good as to prompt us to say you have nothing to learn.—2. For getting the maximum of density with the brand of plates mentioned, give very long development.
H. B.—1. Sulphur. It should be washed to remove the silver and then rejected.—2. An excess redissolves the precipitate.—3, 4, 5. A formula for the sulphocyanide toning bath will be found on page 628 of the *ALMANAC* for the current year.—6. Thorough washing.
HENRY MORTON.—Small Albion presses are made which would stand upon a table. Such presses would, no doubt, do for printing very small collotypes. We do not know the price of them, but it would probably be from 10*l.* to 15*l.* Any dealer in printing materials will quote a price.
DAYLIGHT.—There are no works specially devoted to the subject of lighting and posing the sitter. The only work of the kind that has been published is Bigelow's *Album*, but that has been out of print for many years. Study the published work of the leading photographers; this is the best method of acquiring the requisite knowledge.
R. C. P.—1. There are no means of eradicating spots on collotype plates.—2. There is also no method of repairing the plate when the film gets damaged.—3. In clarifying gelatine with white of egg, the solution should be strained through close flannel, in the same manner as cooks clarify jellies. Straining through muslin is of no use whatever if a bright result be desired.
R. G. M. I. (Edinburgh).—It is only some kinds of blacking on the insides of dark slides that affect the plates, not all. Ebonite is very good, but many object to it on account of brittleness and that it cannot be hinged like wood. Most of the ebonite shutters used are made to draw quite out. To allow of this the shutter must, of course, be specially constructed. Any manufacturer will supply them to order.
W. CONNOR complains that in printing chromotypes he is often troubled with the prints sticking to the glass, although he well waxes it, using the best white wax.—The trouble very probably arises from the use of the white wax, which is very often largely adulterated with spermaceti, &c. Pure beeswax is the best. This is generally best when obtained direct from some one who keeps bees; its purity can then be relied upon.
G. W. S. writes: “In reply to an advertisement I last inserted in your paper, a photographer in a town in the Lake District wrote to me and asked to see my photograph. I forwarded to him at once a cabinet. I have not since heard from him nor received my photograph back, notwithstanding I have repeatedly written and asked him to return it. What means can I take to recover the same?”—Send us the photographer's name and address. You might also communicate with the superintendent of the police in his town.
S. S. S. S. writes: “I am much troubled for an hour or two in the day with the sun shining into one corner of the studio, but I cannot afford to stop out the light there with an opaque blind, and if I put ground glass in then it will stop out just the light I want on dull days. Can you suggest anything that would answer the purpose as well as ground glass, and yet be easily removed when not required?”—The plan we should suggest is to make a light wooden frame and cover it with tissue paper. This might then be fixed up when required, or it might possibly be hinged to the sash, so as to turn out of the way when not wanted.
D. G. T. writes: “Can you assist me by letting me know the best artificial light to use to photograph by night. I have used the flash light very successfully with my friends, but when I get ordinary sitters it is a failure. They seem to move or get frightened when the flash comes, or they have closed their eyes. I want to know can I procure a steady light and one that will take good photographs, and please give me the best means.”—The best artificial light for portraiture at night is undoubtedly the electric arc light, though its introduction is somewhat costly unless there happens to be large installation in the vicinity from which the current can be obtained. Fairly good portraits are, however, obtained with the flash light, though our correspondent appears to fail. We should advise him, failing the electric light, to try magnesium ribbon, using it freely and burning it at a good distance from the sitter.

ALICUIS.—The plate appears to have a medium coating of emulsion—about the right proportion.

CASTLE writes: “I enclose print, and should like to know cause of the bright red and yellow spots. The prints were well washed in galvanised iron pan painted with ‘Aspinal’ inside and out, fitted with a siphon, for about three hours, then allowed to soak all night, and again washed for about two hours—drained and placed between blotting paper, the ordinary white blotting paper. There they were allowed to remain for three or four days (without being seen to). Can the yellow spots be caused by mildew, or are they due to the prints adhering together when being washed? If so, what causes the red spots? Is the blotting paper at fault? I have about three dozen whole-plate size spoilt, and had as many last year. Can you help me?”—The spots are clearly due to mildew. If blotting paper be left damp for several days it usually becomes mouldy. If prints be kept in it in a moist condition, they will quickly become spotted with mould like the one forwarded. The washing of the prints had nothing to do with the evil, it is entirely due to mildew.

RECEIVED.—L. O'Broom; C. C. Vevers; A. M. De Silva. In our next.

CARDIFF EXHIBITION.—The time for receiving applications for space has been extended from the 16th to the 30th of September.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, September 18, 1889, will be *Dark Room Illumination*. Saturday outing at Greenwich.

AT the National Eisteddfod, held at Brecon last week, Mr. John Owen, photographer, &c., Broad-street, Newtown, was successful in carrying off the first prize of 25*l.* in the photographic series of views in the county of Brecknock.

COVENTRY AND MIDLAND PHOTOGRAPHIC SOCIETY EXHIBITION.—We have received the rules, regulations, and conditions by which this exhibition is to be governed. Two silver and two (2) bronze medals are to be awarded in the champion class by the Society, in addition to others by plate makers and journalists. Wall space will be charged for at the rate of sixpence per foot, with a minimum of two shillings. It is to remain open for five days, commencing on October 28th. Entry forms, procurable from Mr. F. W. Dew, Hon. Secretary, must be returned not later than October 19th, and all exhibits must be delivered, *carriage paid*, on or before the 25th.

SMART WORK.—A quick bit of photography in connexion with the Searle-O'Connor sculling match was successfully carried through by Mr. Harold Furniss, of Barnes, on Monday last. Acting on behalf of Messrs. Hare & Co., Limited, the well-known engravers, he took a shot at Searle as he passed the winning-post at Mortlake at exactly forty-seven minutes past one. A bromide print from the negative was delivered at the *Sporting Life* office in Fleet-street at a quarter past three, and a pen-and-ink drawing from it was completed by six o'clock. This was duly engraved by photo-zincography, and the block appeared in the above-named paper the following morning.

THE PHOTOGRAPHIC CONVENTION.—Mr. William Lang, jun., President of the Glasgow Photographic Association, and one of the earliest members of the Convention, writes:—“What is the meaning of those men who were elected at the general meeting on the Wednesday being excluded, and by whom have their names been withdrawn? The thing is perfectly monstrous and irregular. I do not know how others here will take it, but it is quite clear to me that if the different provincial men are to be ignored in this way, then but little success will attend future meetings. It is, of course, impossible that men from the north can attend Council meetings in London, but for all that this ought to have been discussed in an open manner at the meeting, and after being elected I, for one, decline to be simply wiped out without letting myself be heard on the matter. If the Convention is to become a London club then good and well; it will require to have its annual meetings there. But if the leading towns here and in England are to occasionally receive the Convention, I do not see how the provincial men can be ignored. Fancy putting on the Council a certain number of men of a particular town—the town that is being made use of for the time being—and then for ever afterwards ignoring ‘every mother's son’ of them. Selfishness, thy name is Convention! It won't do.”

OUR CONVENTION GROUP PICTURE.

The publishers inform us that a few (not exceeding a hundred) of the Convention Group pictures which were sent out with our issue of last week were inferior in quality to the others, owing to the exceptionally high temperature which prevailed at the time of their being printed, thus inducing a softening of the collotype plate. To meet this, some others have been printed, which will be sent to any into whose hands these imperfect copies may have fallen, and who will return them to us with name and address written legibly on the back.

In the key to the group it will be observed that there are several blanks, representing members whose names we do not remember. Perhaps they or some of their friends will kindly supply the omission, which we will publish at an early date.

No. 1533. VOL. XXXVI.—SEPTEMBER 20, 1889.

HOME-MADE GOLD AND SILVER SALTS.

In our recent series of articles on *Economy in the Printing Room*, we undertook to treat the question of the economy of utilising residues for the purpose of making the salts of the precious metals for studio use, instead of sending to the refiner, receiving cash in exchange.

Let us first consider the silver chlorides and sulphides. It is almost impossible to collect these in a state of absolute purity; organic matter will be thrown down with the insoluble salts, and it would be a most difficult task to ensure perfect freedom from the chance entrance of foreign matter. Otherwise, the chloride—the sheet-anchor of the residue-saver—might be reduced to the metallic state very easily, without heat, by the aid of iron, and the sulphide similarly, but with heat. We strongly advise, in every case where silver residues are to be converted into salts, that the metal is first brought into a state of fusion. In whatever state the silver is obtained, the next step is to dissolve it in nitric acid, and when the nitrate so obtained is to be used simply for sensitising paper it can be used without being crystallised, and will make an excellent bath. It will be difficult to bring the solution sufficiently near to neutrality by simply allowing the acid to remain in contact with excess of silver; but this can readily be remedied. A small quantity of solution is precipitated with caustic alkali (or, even, carbonate), and the precipitate, after being washed, is added by degrees to the silver solution first obtained until no more is taken up. All that is then necessary is to filter the liquid and ascertain its strength by a silver meter when it is quite ready for use.

When it is desired to obtain the nitrate in the form of crystals, the solution has to be concentrated by heat and set aside for crystals to form, and the mother liquors saved for further concentration and recrystallisation. Whether, except as an interesting and costly experiment, it is worth any one's while to make nitrate of silver crystals, except by the thousands of ounces, we leave to our readers to decide after perusing our calculations.

The lowest market price, we believe, which silver has touched is three shillings. Let us work from that low price. As standard silver contains ten per cent. of alloy, we must first find the price per ounce of the silver it contains; if pure silver were bought a certain increase of price beyond the market value would have to be charged for manufacturing it, so to speak; hence we do not treat the subject from that standpoint, but

take market price only, thus giving every advantage to those who would make nitrate.

$$42 \text{ pence} \times \frac{10}{9} = 46\frac{2}{3} \text{ pence,}$$

the market price of the silver in "standard silver."

We readily find the cost of the silver in an ounce of nitrate thus:—

$$46\frac{2}{3} \times \frac{9}{17} = 29\frac{1}{7}.$$

Therefore, an ounce of nitrate of silver costs, for silver alone, nearly half-a-crown; but as the precious metals are sold by troy weight, this is the price of a troy ounce; and, to fully understand the relations of the prices, we must find the cost of an avoirdupois ounce, that being the weight that chemicals are sold by. Therefore—

$$29\frac{1}{7} \times \frac{437.5}{480} = 27 \text{ almost exactly.}$$

We thus learn that the nitrate of silver, which can be bought in quantity at half-a-crown an ounce, leaves a margin of three-pence, or ten per cent. on the selling price, for cost of making, interest of money, waste, labour, and nitric acid!

The question, whether it "pays" any one to make his own nitrate, answers itself, even if no crystallising be attempted and the simple solution of the metal in acid be produced. If we make this into a readily remembered fraction, we may say the silver in an ounce of nitrate of silver crystals, as sold in the shops or stores, costs $\frac{9}{17}$ of the sum per ounce as which silver is quoted in the market reports of the London papers.

Such a margin is not a profit, and at one time the explanation of this "working at a loss" was that nitrate of silver solution was a bye-product in refining, which it was cheaper to turn into crystals than reduce to the metallic form again. But it is now required in such immense quantities that no bye-product could possibly suffice for supplying even a small proportion of the present demand.

The further explanation has been suggested that to sell at such cutting prices adulteration must be practised. Of course, every chemical is liable to adulteration; but we have had the curiosity to make accurate assays of silver nitrate from two separate sources; and, so far from its being adulterated, we found the salts examined to be marvellously pure examples of commercial chemicals—the water present being almost nil, and the total amount of foreign substance a fraction of one-tenth

per cent. Many crystals of other salts sold as "chemically pure" could not show such a register as that.

To calculate the cost of chloride of gold in the same manner would lengthen this article to too great an extent, and we will, therefore, defer its consideration to a future occasion.

THE DESTRUCTION OR REMOVAL OF THE PHOTOGRAPHIC IMAGE.

RESUMING this subject where we left off last week, we shall point out an application of the "reverse" method of working, which presents very particular advantages over the direct plan.

Before, however, referring to these we ought to mention one point which we overlooked in our article last week. It is well known to old collodion workers that an image may be removed by any of the methods of solution already described, and reproduced with the greatest ease by means of any form of acid silver development, notwithstanding that all sensitive material and all visible trace have been removed. This occurs whether the original image has been produced by alkaline or by silver development, and the removal and reproduction may be repeated time after time, provided the plate be well washed after each operation.

In consequence of this peculiar difference in the behaviour of the two kinds of development, some very curious experiments may be performed. For instance, a wet plate, we will say, may be exposed and developed, treated with nitric acid or iron alum, and washed, when it will present the same appearance as if unexposed; it may then be "fixed," when to all appearance every trace of an image, latent or otherwise, will have departed. But on the reapplication of a silver developer the original picture will come up with all its pristine vigour, or even more, and the removal and reproduction may be repeated frequently if the precaution we have mentioned be observed.

Or we will suppose an alkaline-developed collodion positive to have been treated with nitric acid or iron alum, as for the purpose of making a reversed negative, but instead of redeveloping by the alkaline method we will apply acid pyro and silver. At first, or after the lapse of a short period, the negative image commences to form, but gradually the shadows darken and fill up, until the whole surface presents an even shade of blackness on which no sign of an image of any sort is visible. In this case the developer has acted both upon the previously intact bromide and upon the original impression of the removed image, the result being an even deposit of silver over the whole surface. But if the plate be now treated once more with one of the silver solvents, it will be restored to the same condition as after the first similar application, and will present the appearance of a perfectly graduated negative, in which the different grades consist of bromide of silver. If pyro or hydroquinone with alkali be now applied, a perfect negative will result, as these developers have no action on the latent traces of the removed image. This explains why silver intensification should never be resorted to in this process of reproducing negatives.

Whatever the influence may be which remains to enable this repeated reproduction of an apparently destroyed image, the means exist by which it may also be discharged, and the power of redevelopment removed. This consists in treating the plate with solution of chromic acid, preferably in combination with a soluble bromide, chloride, or iodide, and in very particular cases followed by immersion for a second time in the fixing solution. After the treatment, silver development or in-

tensification may be resorted to without any fear of fogging or filling up the shadows of the picture.

In making negatives of line or stipple work for reproduction by any of the photo-mechanical printing processes, it is well known that negatives combining great density with perfect clearness of the lines or stipple are a *sine quâ non*, and it is equally well known that the natural difficulty inherent in this kind of reproduction is increased by the necessity for the extreme density. The tendency, too, of the developing action to spread laterally and fill up the fine intervening lines still further complicates matters, and this class of work is only, as a rule, satisfactorily performed by those who constantly practise it.

But if instead of attempting to intensify the original negative, a positive be made on a collodio-bromide plate, the development being carried to the fullest extent, and this be then treated with iron alum, a perfectly clean negative will result, in which the lines are formed of bromide of silver. This is next treated with chromic acid to thoroughly destroy the previous image, and it is then ready for redevelopment.

In this particular instance, where extreme density is required we should prefer, before redevelopment, to treat the film with a moderately strong solution of iodine to convert the image into iodide of silver; then, after a very thorough washing, flood it with a solution of nitrate of silver, expose to light, and proceed to develop with pyro and citric acid, when a negative combining perfect opacity with absolutely clean glass will be the result obtained with an ease entirely unknown in the direct method. In this manner such fine work as the "wet" negatives for photo-mechanical printing processes are admirably executed.

HAS the substitution of dry plates for wet ones in the studio been any very great advantage to operators generally in large establishments? We do not mean from the point of convenience, and the relief from the worry and anxiety when working with wet plates, such as the drying of the film on hot days, the risk of movement on the part of the sitter during a prolonged exposure, and similar troubles. The advantages of dry plates from this point of view are incontestable. But have they tended to shorten the hours of labour or otherwise? In the wet-plate process the negative had to be developed directly it was exposed, and the fixing followed immediately. In fact, with collodion, so far as the operator was concerned, the negatives were always finished within a few minutes after the sitting, and were usually all dry and ready for varnishing by the time for closing business; hence the hours of the operators were necessarily comparatively short. Now, we understand, it is customary in some houses to defer the development of a large proportion of the negatives until the business of the day is over. Consequently, it is no unusual thing for operators to be fully occupied till eight or nine o'clock at night, for it must be borne in mind that as a rule, a larger number of negatives of each sitter are now taken than used to be the case formerly. This makes long hours to work in an oppressively hot studio during the day, and in a small, and too often ill-ventilated, dark room for the whole of the evening. To operators so situated dry plates can scarcely be considered such an inestimable boon.

In the wet-collodion days one of the greatest essentials in an operator was the ability to prepare and keep in order his chemicals, so that the plates could always be in the best possible condition for the camera. Here, it must be admitted, considerable experience was necessary to obtain good plates under constantly varying conditions. No such skill, at least in this direction, is required now that the plates are supplied ready for use. Yet we hear loud complaints that really first-class operators are quite as difficult to obtain as when the wet process was in vogue, if not more so. This fact was accounted for to us by the principal of a high-class establishment, a few days back

as follows:—"When a man becomes a really first-rate operator he prefers to be his own master, and generally finds the means to commence business for himself." We have little doubt but that there is a great deal of truth in this statement. Certainly there is a considerable amount of common sense.

COMPLAINTS are still rife of the detention or appropriation of operators' or retouchers' specimens. To retain specimens of the work of an operator seeking employment is contemptible. But when they are kept and exhibited as specimens for the showcase, or the reception room, it amounts to one of the most deliberate and cruel frauds that can well be perpetrated. It is nothing short of swindling. When specimens are sent and not returned in due course, we shall be glad to have the names and addresses of the offending parties.

OPERATORS and others, in answer to advertisements, should forward specimens only to those who give their *bond fide* names and addresses in full, and not to anonymous advertisers. We have heard of instances where those who have done so have afterwards seen their pictures shown as examples of the exhibitor's own work. Clearly, in such cases, the pictures were obtained under false pretences, and we question very much if the offenders could not be prosecuted in the police court. We are not aware, however, that proceedings of this character have ever yet been instituted. Operators out of employment rarely have the time or the money to expend in legal proceedings. However, when specimens have been forwarded, and their return cannot be obtained, a note detailing the circumstances, addressed to the superintendent of the police of the district, will usually lead to their restoration.

THE non-return of specimens must not always be attributed to actual dishonesty, as it sometimes arises from negligence, oversight, or accident: or it may be from thoughtlessness. A few prints are often looked upon in a photographic establishment as of little value. So they may be, intrinsically, but they are often of inestimable value to the owner, as perhaps they are the only ones he has and are, therefore, his only hope of obtaining a situation. From whatever cause the specimens are not returned the hardship is all the same to the unfortunate *employé*. Sometimes, however, the fault does not rest with the receiver, but with the sender. Often the reply to the advertisement is by letter, while the pictures are sent by book-post, without any intimation as to whom they belong, and perhaps the wrapper gets mislaid or destroyed. If the owner's name and address were written on the back of each photograph mistakes of this kind could not occur.

THE business in the cheap varnished lithographic views of seaside places does not appear to be at all diminishing. Collotypes, bound up in a similar fashion, and at about the same price, are to be had in some districts, but their sale, we learn, is nothing approaching that of the lithographs. Strange as it may appear, we are informed that many of the public actually prefer the lithographs to the collotypes, as they say they are more clear and distinct. If hardness and crudeness, in the eyes of those who prefer them, means distinctness, then the lithographs certainly have the advantage over the collotypes, which, for the most part, are fairly good work. Somehow or other collotypes are produced at a very low rate. We have before us, as we write, some collotypes of a fashionable seaside resort, of the half-plate size, mounted on an elaborately embossed cardboard mount in imitation of a frame, and measuring about twelve inches by ten, with a ring to suspend it by, which were purchased *retail* at a penny each. When it is considered at what price they must be sold at *wholesale*, it would appear that collotype printing must carry a very good profit at the prices sometimes charged.

A MODIFICATION IN THE STANNOTYPE PROCESS.

IN an "Answer to Correspondents" a week or two ago, mention is made of a means of obtaining relief in a negative by coating with bichromated gelatine, and exposing through the negative, afterwards developing in warm water. I have never previously seen this

suggestion in print; but it is many years since I first tried it for another purpose, and five or six years since I practically utilised it in connexion with the stannotype process.

As far back as 1864 or 1865, very shortly, in fact, after the publication of the details of Swan's carbon process, I adopted, or attempted to adopt, this plan for simplifying the production of the "tissue." It will be remembered by some of my readers that Mr. Swan's first tissue was made by spreading the bichromated and coloured gelatine upon collodionised glass plates, from which it was stripped when dry, and printed collodion side towards the negative. It was then attached with indiarubber cement to paper for development. The stripping but especially the necessity for a double transfer process in order to produce an unreversed image, seemed to me very irksome, so I hit upon the very ingenious (?) plan of coating the varnished side of a negative, previously rubbed with oxgall, with the sensitive pigmented gelatine, and after drying exposed through the negative in the ordinary manner.

The development was performed while the tissue was still *in situ*, the negative itself taking the part of universal support; when finished, a final support of paper was attached by means of gelatine, and when this was dry the print was stripped from the glass. I say from the glass and not from the negative, because it is scarcely needful to remark that the latter came with the print, or, at any rate, *most of it* did, for the glass not having been specially prepared for stripping, portions of the film stuck. With a little ether and alcohol I removed the negative image from the print, and laid bare, perhaps, the best carbon print I had succeeded in getting up to that time.

It would scarcely be worth while at the present day to make your own tissue, for the sake of utilising so simple (?) a process for producing one print, but the application I am about to describe is a really practical one, and saves a great deal of trouble to those who may be working in a small or experimental way.

From your recent description of the stannotype process, in the number for July 5, the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY will know that in this process a relief in gelatine is made from a positive instead of from a negative, as in the original Woodbury process, and that this relief itself, faced with thin foil, is employed as the actual printing surface, instead of, as in the other process, being pressed into a plate of type metal to produce a "reverse."

Now, the greatest trouble in the process lies in the making and drying of the tissue employed for the relief. It must necessarily be very thick, that is to say, very much thicker than ordinary carbon tissue. It must be absolutely faultless in character, that is, free from dust and other imperfections; and as its great thickness results in very slow drying, it will be seen that the operation is not a comfortable one, and, so far as I am aware, the article is not obtainable commercially.

There are two methods of proceeding, each of which has its disadvantages, while neither is remarkable for any special features to render it a desirable task. The one consists in mixing the bichromate with the gelatine before pouring out, which presents the advantage of giving a tissue that is ready for use when dry, but the serious disadvantage that the gelatine is liable to become partially insoluble during the long drying, especially if gas or other fumes get into the drying chamber, and it is, above all things, essential that the full solubility of the unexposed film should be retained. The other method consists in making and storing the tissue in an insensitive condition, but this, of course, necessitates after-sensitising and a second drying, in the course of which it is very difficult indeed to prevent the thick gelatine from twisting and warping in such a condition that it is impossible to get contact with the negative.

The tissue is made by squeegeeing moistened paper on to the bottom of a shallow tray, and pouring the gelatine in to the required depth. If this plan be adopted, when the gelatine has set hard the paper can be lifted bodily from the glass, and the tissue will then dry much more rapidly, but with a strong tendency to curl and warp. The plan preferred and recommended by Mr. Woodbury himself was to rub the bottom of the tray with talc or wax and collodionise, pour in the gelatine, and, when set, to squeegee the moistened paper on to the surface.

It will be seen, therefore, that the trouble of making the tissue is very great, but in practice the greatest difficulty is in the handling or using rather than in the making, as the thick gelatine tissue is so

refractory. For instance, to one even well accustomed to the development of ordinary carbon tissue, it will at first be next to impossible to get the Woodbury tissue to adhere to its support during development, even if everything has gone right up to then, and if any loosening occur it is fatal to the relief.

As a way out of many of the difficulties when working stannotype, some years since I resorted to the plan of applying the pigmented gelatine directly to the transparency. By this means there is no necessity for stripping, no danger of curling, absolute contact in printing, and the transparency itself becomes both the developing support as well as the final support for the relief in printing, for which latter reason it is essential that it be made upon plate glass.

When I suggested the plan to Mr. Woodbury, he recognised at once its advantages under some circumstances, and we tried it together, but not with very favourable results, though the cause was not attributable to the process. As a matter of fact, Mr. Woodbury invariably employed carbon transparencies for printing the relief, and unfortunately, by this method of working, the relief of the transparency and the hollows or intaglio of the mould coincided, and *vice versa*, and to a certain extent neutralised one another, the result being a general flatness and total absence alike of high lights or depth. Later, however, I tried the plan with gelatino-bromide as well as collodion transparencies, and found this the easiest and best way of working.

It may be said that if the relief proves a failure the transparency is lost. So it is, and if it were the case of the original negative, or if the transparency is the only one existing, this would be a fatal objection. But if the negative is in existence, it is so easy a matter to make another transparency, or to reproduce a transparency where the negative is not available, that the objection falls to the ground. In the ordinary way of working, when a successful relief has been made, the transparency is of no further use and has to be cleaned off, so that may be put as a set-off against the necessity for cleaning off a spoilt relief in the other case.

Mr. Woodbury, as I have said, invariably used carbon transparencies, and, after those, placed "in order of merit" collodion emulsion. Gelatine would not do at all, at least not in those days—I am speaking of seven or eight years ago—though I see no reason why it should not now. I made several gelatino-bromide positives for him, but none came up to his requirements—*absolute clearness and transparency in the lights*. That was before the days of "sulphite," and the pyro stain in the transparency lowered the whole tone of the relief made from it.

To explain this I ought to describe the principle of the double "safe edge" necessary in stannotype. In the first place, the transparency is printed with a perfectly clear margin of, say, a quarter of an inch all round. In the case of a carbon print it will be obtained as a matter of course from the "safe edge" employed on the negative, but whether the positive be carbon, collodion, or gelatine, this perfectly clear margin must be provided.

But if this transparency were at once used for printing on to carbon or Woodbury tissue, the margin would be rendered insoluble and repellent, and would never adhere to the developing support, for which reason it is absolutely necessary to provide the transparency with a second "safe edge" by pasting opaque or semi-opaque paper, or by applying pigment to the depth of an eighth of an inch all round the plate, which will then be surrounded by an outer strip, opaque or nearly so, and an inner one perfectly transparent, then the picture.

Now, in the relief the outer band will consist of a depression, or, looked at by transmitted light, would represent nearly clear glass; the next or inner band represents the fullest action of the light, and is the highest relief that exists in any portion of the plate. It regulates the thickness of the layer of ink that forms the picture, and constitutes the absolute high light on the zero from which all others start.

This being the case, it is clear that if the high lights of the transparency are at all veiled or stained, those parts cannot stand so high in the relief as the margin, and consequently a layer of ink of more or less thickness be deposited on them and so degrade them. There is, in fact, no zero to the scale of such a picture.

But this is a digression I have indulged in merely to explain the

kind of transparency required for this process; and as transparencies are so easily made by either gelatine plates, or for this purpose, perhaps, better with collodion emulsion, I think the modification I have outlined will be found a great saving to all workers of stannotype.

W. B. BOLTON.

ECHOES.

THE suggestion contained in Mr. W. M. Ashman's "Convention" paper, to found an Institute of Photography as a memorial to Fox Talbot, is a good one, if it could only be properly carried out, which I think would be very unlikely. I do not mean for a moment to say that the thing is impossible, but that under existing circumstances the chances are strongly in favour of the whole job being spoilt. If the objects of the Institute were to be the furtherance of the science of photography, it is long odds that it would drift into the hands of the "South Kensington clique," with the usual result. If, on the other hand, a merely technical training for commercial purposes were aimed at, I think it would be a pity to take the work out of the hands of those who already execute it—the technical institutes who specially lay themselves out for that class of work.

If such a movement were set on foot the aims should be scientific rather than commercial, dealing with the chemistry and general technique to the utter exclusion of the mere money-making element. The management should be in the hands of men of high scientific standing, not merely successful photographers, and it must be confessed that as yet the ranks of photography number but few of the right sort. I do not say there are none who have not some claim to eminence in photographic science, but the very paucity in number ensures that they would, in any case, be consulted by Government, or any other authority, with the inevitable result that photographers would have the pleasure of paying for what would be practically another branch of the South Kensington Nursery of Science.

On reading the editorial article in the series of *Neglected Processes* devoted to Warnerke's "new" (how time flies) "process," I could not help agreeing with the expression of surprise that so little use has ever been made of it. I do not know if the patent is still in existence, or whether it is free to be worked by any one who may choose to do so, but there are many applications of it which would prove eminently useful.

One especially, with which I worked experimentally some years ago, I will make a present of to those interested, though it is quite probable that the idea may have already occurred to others besides myself. In photo-zinc work blocks are frequently wanted at a few hours' notice, at periods and on occasions when the light is so bad that the ordinary methods of transferring the picture to the etching surface are useless. By Warnerke's method, however, a drawing or sketch may be photographed on to rapid sensitive gelatine paper by artificial or other light, developed, squeegeed on to the zinc, treated with hot water to remove the paper support and soluble gelatine, and the remaining image forms the "resist" for etching. The whole process of taking the negative and transferring to the plate ready for etching need scarcely occupy more than a quarter of an hour.

Of course, a specially thickly coated paper would be necessary, and if not a specially soluble gelatine, at least no alum or similar substance must be used in the preparation. Once, in the very early days of gelatino-bromide paper, I succeeded in getting a result *à la* Warnerke on the commercial article, but since that time so much alum appears to have entered into the composition of commercial emulsions that the papers are entirely unsuitable. If the patent has lapsed, I think it would pay some manufacturer to place on the market a paper thickly coated with an emulsion made from perfectly soluble and preferably English gelatine.

I am rather reluctant to differ from any statement editorial, but I cannot help thinking that the commendation awarded in a leaderette a fortnight ago to the novel method of folding a filter attributed to Mr. Fessenden, Edison's chemist, was written before the plan had been tried. It is certainly ingenious, and reads very well on paper, for which reason I very soon proceeded to try it. But here I got into difficulties at once, for there are various ways of reading the directions, to clip it "between opposite folds," &c. Commencing by clipping two opposite folds in such a manner as, while keeping the thing together

the centre of the filter remained open for use, I found that the angle presented by the sides was so obtuse that the filter would only lie across the mouth of the funnel, and that any liquid poured into it flattened it out and escaped over the sides. Even when folded up close, as when inserted in the schoolboy's "dart," the angle presented by the junction of the four separate wings is far too obtuse for the ordinary funnel; however, I tried clipping it across "between opposite folds," so as to keep the centre closed. This practically converted it into four distinct filtering compartments, the sides of which are composed of a single thickness, and under the weight of liquid the paper gives a little to the angle of the funnel, but still "wobbles" very seriously. My trial was made with a good stout sample of paper, and even this would not nearly bear being filled, so I do not know how the thin Swedish and English papers would answer. Perhaps I have not yet got at the right way of clipping.

Nevertheless, I have derived some advantage from the plan by a slight improvement that converts it into a nearly perfect filter. When folding the paper, fold with and *outside* it a piece of stout cap muslin, or, better, hair gauze, such as is used for making sieves. Instead of clipping it as above, run a couple of pieces of string through between the opposite folds, and, rejecting all funnel assistance, suspend the arrangement from any convenient support. Now every portion of the filtering surface—of a single thickness—is firmly stayed by the gauze, and filtration is both rapid and safe. The danger with the pleated filters and those not in contact with the sides of the funnel is that they are so liable to break at the folds.

In another leaderette wonder is expressed that so little ingenuity has been exhibited in the protection of the rollers and plates of our rolling machines. Silver I have had no experience with in connexion with rolling presses, but nickel I have seen come off in scales, both after constant use and after practically no use at all. Moreover, it is, to my idea, more trouble to keep in order than unprotected polished steel. My experience with a tricycle "plated in parts" was decidedly not favourable to nickel. If left for a day or two untended, especially in damp weather, the nickelled portions became absolutely "blue mouldy," or something very like it, and it was only by the most assiduous attention and constant polishing that the plated parts were kept at all decent. In consequence, they required renovating long before the enamel showed any signs of deterioration, and before the unprotected screwheads and outs, that had received less care, had lost their brightness.

The suggestion to employ the Bower-Barff process is a good one, but the question naturally arises, Will it answer? I have seen some beautiful results by the process, and there can be no doubt whatever as to the suitability of the surface for rolling purposes. But will it last? The film of oxide must be infinitesimally thin, which, though it promises that there shall be no "shelling off," rather suggests that it will not long withstand the temptation to rub off under the heavy pressure of work. However, the best way to settle the question is for somebody to have his press "Bower-Barffed."

It has been said that photographers, as a body, are too much given to "jumping at conclusions without sufficient ground to jump from." I don't like to differ from Mr. W. H. Sherman, who has made many excellent suggestions in photographic, especially printing, matters; but it seems to me he is acting up to that principle in attributing blisters in albumenised prints to the over-saturation of the bath with nitro-albuminate of silver. I can see little force in his arguments, and little connexion between his facts and the result. My own experience is, that if a paper means to blister it will do so with equal freedom whether the bath is old or new, used or unused, the only element that at all tends to modify the result being the strength of the bath in silver, not its freedom, or otherwise, from organic matter.

Apropos of the very slight differences in working that will produce identically opposite results, I may mention a case in point of blisters that was related to me some time ago. Two individuals divided a ream of paper between them, and one soon commenced to complain bitterly of blisters, while the other was quite free from them. The unfortunate one tried everything he knew; changed his samples of silver, gold, and hypo to the same as those his friend employed; used the same strength of bath, the same toning formula, and in fact left, as he thought, no stone unturned—but still blisters. So he got his

friend to pay him a visit and see if he got blisters when using the same materials. He did not; for when he came to fix, it turned out that he was in the habit of using less than half the strength of hypo!

JUNUS.

LANTERN SLIDE MAKING.

[A Communication to the Birmingham Photographic Society.]

To some extent the amateur photographer is bound to admit that his long periods of seclusion in the dark room render his hobby a somewhat selfish one, at least so far as his non-photographic friends are concerned. How often I have been reminded of this I scarcely care to think. Happily for me, a lingering desire to possess an optical lantern became a firm resolve. The instrument once at home, the temptation to increase my limited number of slides was, of course, irresistible. On the conclusion of my first display the universal congratulations convinced me that my efforts were appreciated, and, strange to say, resulted in the withdrawal of all further opposition to "that dark room terror," as my sanctum was designated.

My knowledge of the "wet" negative process aided me considerably for a time; it formed the basis of my operations. I found, however, the deposit was coarse, and that a different developer to that used for negatives was necessary.

Fifteen years ago photographic literature, especially that suited to the amateur, was by no means plentiful, and one could often seek in vain for information now afforded in every elementary handbook. This led to experimenting and careful observation on my part, and I believe that schooling was very beneficial—so much so that I cannot but regret the meagre superficial knowledge possessed by the average amateurs of the present day.

Let us consider the requisites of a good lantern picture. First, of course, comes artistic composition, the arranging of the subject in such a manner that as the eye wanders over it its beauties continue to grow, and the imagination receives an unalloyed feast of satisfaction and pleasure. To some extent I think it possible to teach the art of composition—at all events so far that its simplest canons may escape violation—but the capacity of rendering true art is a gift of nature. Secondly, the technical excellence of the picture, its mechanical production—upon which, with your permission, I shall address you this evening.

The wet process, properly understood, I believe it is generally admitted, yields the best results in many cases. That it is at times a somewhat troublesome process I frankly admit, still, with care and observation its difficulties can be overcome. I shall treat of the collodion process only, leaving that of albumen for a future paper. Collodion (that is pyroxyline dissolved in ether and alcohol) forms the vehicle to receive the sensitive salts, and a collodion that has been iodised some time is necessary, otherwise the high lights of the pictures will suffer. Thin glass cut to the standard size is taken, and after standing some time in sulphuric acid and water it is carefully dried with a cloth free from soap or other grease. One side of the glass is then coated with the following solution, which must first be filtered through filter paper:—

White of one egg, well beaten.

Ammonia liquor '880 1 ounce.

Water (according to quantity of albumen) 15 to 20 ounces.

The coating is performed by pouring a small pool in the centre of the plate, then gently inclining it so that it runs to each corner—the excess may be thrown away.

So soon as the plates are dry they are ready for use. With a soft brush carefully dust the prepared surface, flooding it with collodion in a similar manner, but returning the excess to the stock bottle. This is to avoid dust, a serious enemy. During the draining the corner should be kept in contact with the bottle, and the plate gently rocked to avoid a streakiness or uneven setting of the collodion. Directly it is sufficiently set (the best test for which is trying the upper corner with the finger) it is steadily and evenly lowered into the sensitising bath by means of a dipper.

A good bath for lantern slides is made as follows:—

Pure nitrate silver recrystallised 40 grains.

Water distilled 1 ounce.

Rendered slightly acid with C.P. nitric acid, one or two drops of which will be sufficient for 12 ounces of solution.

When the bath is mixed, for each twelve ounces add half an ounce of the iodised collodion and shake very thoroughly, let stand a couple of hours, then filter. The bath should now be quite clear and in good working order, but may occasionally be placed in the sun for a

few hours and afterwards filtered, when it will work cleanly until the silver is exhausted.

When the plate has been in the solution about two minutes it should be slightly moved to help the escape of the solvents, and in about four minutes may be examined by yellow light. If the surface is free from greasy lines it is ready for exposure in the camera.

A good negative is necessary for a successful slide. It should be "plucky," so as to admit of a fair exposure.

A good developer is made as follows:—

Protosulphate iron	$\frac{1}{2}$ ounce.
Acetic acid	2 $\frac{1}{2}$ ounces.
Honey	1 ounce.
Alcohol	$\frac{1}{4}$ "
Water	16 ounces.

Use plenty of developer, and cover the plate in one even wave, never mind spilling a little, but practice will enable you to avoid this. As soon as all detail is well up, thoroughly wash and intensify with—

Pyrogalllic acid	24 grains.
Citric acid	24 "
Acetic acid	$\frac{1}{4}$ ounce.
Water	24 ounces.

Enough to cover the plate is taken, to which, immediately before use, a few drops of the silver bath is added.

Do not over intensify, as the picture does not loose much in fixing, for which operation hyposulphite of soda may be used on the ground of safety, but cyanide of potassium acts more quickly and perhaps more cleanly. Slides by this process are a good colour, and do not need toning. A coat of clear varnish improves the transparency of the shadows. The apparatus for lantern slide making, patented by our member, Mr. W. Griffiths, is very handy and cheap. I have one here for your inspection. The slideholder requires to be made in wood, with silver wire corners to adapt it to the wet process.

I am quite aware that the dry plates now made for lantern slide purposes are very popular, and I think most of them deservedly so. Personally, I use a lot of Messrs. Fry's, Mawson's, and Thomas's. My various sets of Norwegian slides, numbering some hundreds, are made upon them, and I will next show you the methods of development most successful in my hands.

Whether printing in contact or by means of the camera, I strongly recommend a full exposure. Gelatine plates are sure to show fog if forced, and however slight that may be it should ensure their immediate rejection. Indeed, it is well to select a really good slide as a standard both as to density, tone, and clearness in the high lights, and those that do not come up to it should not be kept.

For dry plates I prefer a soft negative full of detail. If the skies are not sufficiently opaque they must be stopped out.

The solutions required are ten per cent. ones of the following:—Pyrogallol, bromide of potassium, ammonia, carbonate of ammonia, and carbonate of potash.

The pyro is mixed as follows:—Four ounces of sulphite of soda are dissolved in boiling water and rendered acid with citric acid. The pyro is then added, and the whole made up to ten ounces with water.

The other chemicals are simply mixed with water, and all will keep well. A developer giving a beautiful purple tone with Mawson's and Thomas's plates is—

Pyro solution	30 minims.
Bromide	30 "
Ammonia	30 "
Carbonate ammonia	30 "
Water to make up to	1 ounce.

The same colour can be obtained with Fry's plates by slightly increasing the exposure and bromide, while a fine engraving black is got by shortening the exposure, increasing the ammonia, and leaving out the carbonate of ammonia.

Sepia is obtained by full exposure and using carbonate of potash or soda in place of ammonia, but some makes of plate will not yield the sepia tone.

While the plates are developing keep them in motion, it adds to their vigour, and prevents flatness, and also deposit settling upon them.

After fixing and moderately washing they may be cleared in—

Alum	2 ounces.
Citric acid	$\frac{1}{2}$ ounce.
Water	10 ounces.

The addition of two ounces of protosulphate of iron and a quarter of an ounce more of citric acid will considerably moderate the tone, and by slightly reducing the slide increases the clearness of the high lights.

If any deposit appears upon the surface rub gently with the finger or a tuft of cotton wool. The slide is now well washed, allowed to dry slowly away from dust, and then varnished.

I will now proceed to make several slides, which I will afterwards exhibit on the screen by means of the oxyhydrogen lanterns, and show the various tones obtainable by the variation of the developer. The results both by wet and dry process, you will see, are equally good.

E. H. JAKES.

PRACTICE AND THEORY.

PRACTICE and Theory should go hand in hand—one supported by the other; if they do not agree, it is very certain there is something wrong somewhere. It is proposed in the following article to touch a little on both the theory and practice of taking photographic negatives and printing them—printing being the ultimate use to which such negatives are put, and may be expressed in silver, platinotype, bromide, or carbon. Negatives produced especially for photo-mechanical work will not be taken into account, for their useful career is ended when the blocks are made. Photographic printing methods, such as are familiar to most photographers in their everyday practice, will be the only kinds that will come under consideration. It is well known that by skilful printing very indifferent negatives can be made to produce good results, but undoubtedly the best negative will produce the best work (other things being equal) with the least trouble and least waste of material. How to produce the best possible negatives, or how the best possible negatives should appear when produced, has hitherto been a much debated question. Opinions differ; much depends on the purposes for which they are required, or the special effects aimed at; for the very best process, if there is a best, and the very best negative, will in some hands only produce very indifferent results.

Qualities which have hitherto been considered *essential* to good work, as, for instance, brilliance and delicacy, have, by a recent writer on photographic art, been somewhat pilloried as faults; the essential quality of such negatives as points of absolute clearness and absolute opacity, rejected as something that had not ought to exist and evils to be avoided. A soft half-tone pervading the whole composition is set forth as about the only quality a good negative should possess, definition being altogether antagonistic to artistic results. No one will dispute that softness is a very good quality when combined with something else, but *alone* leaves much to be desired. In any kind of print in which half-tone exists, the greater the range of gradations the better the picture. To get this scale, we must have negatives with clear glass in the deepest parts and absolute density in the lightest—it does not follow there need be much of either, so long as these extremes exist it is sufficient. The printing of the negative regulates the final tone and harmony of the production, but to start with any chance of success the negative must possess these qualities. The *general* density of negatives may vary—in fact, ought to—to fit them for the kind of surface on which they are to be impressed. A matt surface or salted paper requires a stronger negative than for bromide printing, on which a negative so thin as to be unsuitable for other work gives the best results. A perfect negative will, however, give *good* results on any surface, although different densities for different processes are practical advantages not to be neglected, one of the principal points of which is freedom from waste. In looking through a number of prints from a negative that is not so good as it should be for the work required, it will be found that they (the prints) vary very much, both in colour and brilliancy. One out of a dozen will probably be infinitely superior to the others, the one causing dissatisfaction with the rest; but, on the other hand, given a suitable negative, there will be evenness of results, possibly all the prints will be good, or at worst but very few that it will be necessary to discard: this consideration is of very great importance where much work is done. Those who advocate flat negatives are certainly not well versed in photographic printing, and possibly are satisfied if by dint of frequent trials they can get one or two good and satisfactory pictures. However this may be, a negative deficient in scale will never be popular with those who have to print them, on the score of difficulty in getting uniform results. Connoisseurs will note their want of "sparkle," which, by-the-by, does not mean either hardness or loss of detail in the shadows, but simply a quality of freshness and brightness throughout the whole work. It is patent to every one acquainted with painting, or its associated arts, that it is a matter of impossibility to equal by any process the brightest lights or deepest shadows to be observed in nature; so artists and photographers approach it as nearly as they can by starting with pure white at one end of the scale and pure black at the other, not that there should be much of either. We see the most absolute blackness in nature when we look into the mouth of a deep cave, the

interior of which is absolutely devoid of any illumination; in such case we see the blackness is simply produced by absence of light—there are no reflections, nothing to reflect; the blackest paint or the deepest photographic colour would be, by comparison, grey.

Since we are handicapped so severely in our power to imitate, we, by judicious contrasts, increased the apparent force of light and shadow. Hazy indistinctness, an effect so dear to painters, is almost the only method of representing atmosphere with fidelity, or producing an effect of realism on the observer. At any rate, it is the plan generally adopted. With photography, atmosphere can be obtained without blurring or imperfect focussing. Suppose we examine a landscape critically on a perfectly clear day—no one would venture to say atmosphere was absent. Clear as it might be, objects in the distance would be fainter, bluer, and lighter in colour than those in the foreground, but *not blurred*. The time by a church clock might with a telescope be read if miles distant. We only see these things through a veil of minute particles; the deeper the veil the more indistinct objects become, till, in the end, they are altogether obscured, and the land merges into the sky, or, as Professor Hartley says, the blue colour of distance is owing to the presence of ozone. We, therefore, in this case get the impression of distance through a perfectly transparent but coloured medium, and it is only when there is a considerable amount of heat radiated that an indistinct outline in a transparent atmosphere is given, and this is owing to the mixture of atmospheres of different degrees of density, the heat radiated from the ground mixing with the cooler air above. Therefore it is not absolutely wrong to give blurred images to represent distance; but sharp images are equally correct, providing they do not err in colour and intensity. An argument advanced in favour of blurred images is that the human eye only sees one small space sharply at one time. This is right enough so far as it goes, but we must also take into consideration that the eye involuntarily and rapidly is always changing its focus to suit the different planes, so we practically see everything sharply defined when we look at a landscape, *unless* the view is interfered with by local conditions. There is also an involuntary movement of the head to see things that lie to one side or the other of the line of sight. The lens will include all this, being stationary, on account of it being constructed to include a much wider angle than the natural eye, and this extra angle is practically equivalent to moving the head. The perception of atmosphere, in all probability, differs in different individuals, and is dependent in a measure on the personal equation of the observer—in fact, on the sharpness of his sight. As the lens has no personal equation, and can see, so to say, far more distinctly than the most acute vision, depicting objects with much greater clearness than many persons can appreciate as a true rendering of nature from their own standpoint, they challenge its accuracy. No one will dispute that different persons see differently, and effects that will be vividly striking to one will be unnoticed by another, not because of lack of art education (although this is an important factor when we come the purely artistic), but simply because of a variation of strength of sight. On this hypothesis it can be readily understood why some efforts rendered by photography convey different impressions to different persons, why some insist on definition and some on fuzziness; either effect to one particular observer is correct and the other wrong. It is the case of the gold and silver shields over again. I cannot help thinking that the out-of-focus method advocated so strongly is wrong on every point, unless photography and picture-making are to be divorced for ever and aye. My idea is to get atmosphere by the proper exposure and development of as sharply defined a picture as the lens will give, worked with a judicious art knowledge.

The use of wide-angle lenses for ordinary work is a mistake, both photographically and artistically, if the whole of the angle given by the lens is included in the picture. A photograph taken with a lens giving ninety degrees on the base line would in most cases look out of drawing, awkward, and inartistic, the foreground would be much exaggerated, and even examined from a near point of view, say the length of the lens focus, or by bending the picture into a concave form, it would look unnatural and unsatisfactory; but cut off a considerable portion of the margin of the picture, the central part would not only be quite correct but appear so. Any attempt to include an exceptionally wide angle in the view from a stationary camera with a wide-angle lens is simply courting failure, from an artistic standpoint, for all but very exceptional subjects. EDWARD DENMORE.

(To be continued.)

CONTINUATING ACTION OF LIGHT.

THE statement, casually encountered, that where it is suspected insufficient exposure has been given to a surface of silver bromide the postponement of development for a time, presumably weeks or

months, will remedy the error, or, in other terms, effect such a reduction of the sensitive body to the state of sub-salt as to obviate any deliberate deviation from one's normal course of developing procedure, appears to invest the action of light upon the silver compounds with a property not hitherto generally assigned to it, and to be worthy of something more than passing scrutiny by reason of the considerations to which, if the theory, besides novelty, has the features of feasibility, the assertion must give rise.

Every one is aware that the precise change produced in the silver compounds by light is far from being clearly proved and understood, and that the explanation most commonly received is that the action is chiefly, if not wholly, a reducing one, thus symbolically represented: $2 \text{ Ag Br} + \text{Light} = \text{Ag}_2 \text{ Br} + \text{Br}$. In taking a photograph, when we have arrived at an approximate idea of the relative sensitiveness of the emulsion we are employing, and have familiarised ourselves with the respective "values" of our lens and the light on the picture sought to be obtained, the practical realisation of the above equation, which may be broadly esteemed as the small pivot upon which modern photography mainly turns, is only a matter of the impression of the illuminated object upon the plate for so many seconds or fraction of a second, and nothing more. Certain portions of the haloid salt suspended in the gelatine film are thereby altered to the condition of sub-salt, and this, scientifically expressed, is the attainment of the immediate end we had in view when removing the lens cap or setting the shutter in motion.

That the action of light is a continuing one, that it is prolonged and sustained after the effective rays have been cut off, to the instigation of further chemical changes than those actually induced by the prescribed and measured impact of light, which we call the exposure, is a theorem that the present writer does not remember to have seen previously put forth in relation to the subject of the undeveloped negative image. All the same, as it is not an easy affair for an individual to possess himself of the gist of a literature that has expanded so immensely as that of photography, there is the saving chance that the fault is his own. However that may be, it would be rash at the first blush to argue that there is any law insuperably antagonistic to the principle of continuation; indeed, on simple, physical grounds it might be permissible to urge much in support thereof, were it not for the awkward fact that it may be closely established from the positive evidence of practical experience that the assumption of a continuing action of light in the silver salts is unwarranted and erroneous. As it is, a fair inference that a remark of the tendency of that with which these lines are prefaced is animated either by a belief in the correctness of the continuing theory, or some imagined substantiation of it in real practice, there is no need to apologise for the demolition of what I respectfully regard as a pure delusion, or, at least, its relegation to the airy regions of the mythical.

Let it be provisionally granted that the action of light is sensibly prolonged after the duration of the exposure of the sensitive film in the camera, although it is not appreciable until the lapse of weeks or months, and there is an end at once, in an enormous number of instances, to the comparative value of experience, judgment, exposure tables, photometers, as aids to the proper observance of the great and vital preliminary in photography—the exposure. Most persons of average sense, by the way, need no such assistance to the estimation of exposure; tables and photometers are the absurd encumbrances; but this may pass. What are the phenomena that are irresistibly prominent if we countenance the existence of this curious after-property of light? That there is always more or less danger of the effects of over-exposure in deferred development; that correct exposure in the camera must be rarer than we imagine, or that it is either largely dependent upon the length of time that passes between the removal of the plate from the slide and its treatment under the developing agents, or the merest guesswork. Furthermore, these phenomena inevitably split up into several sub-sections not less extraordinary than their parent stems. For instance: if correct exposure be given in the first case, then, on account of the continuing action, the image at the moment of development should—nay, must—exhibit symptoms, the seriousness of which is to be gauged by the time that has elapsed since exposure of being more or less overdone; this law issues naturally and symmetrically from the primary theory of continuation. In short, not to particularise too minutely, to a very ordinary mind a perfect crop of wild anomalies and perplexities must suggest themselves from the insurmountable fact that continuation cannot possibly be arrested in the sensitive body at any stage of reduction, but that so long as there is allowed to remain a layer of haloid capable of being influenced by light, so must the reduction by continuation proceed remorselessly to the bitter end of—solarisation? or what? It is impossible within the limits at one's command to pass in review even a few of the strange aspects in which photography would be, and ought

to have been, revealed to us if the theory were confirmed and reared on high for general acceptance; in the common phrase, they are more easily imagined than described.

It will not, I conjecture, be gainsaid that a statement of such a character seriously made in a technical publication requires to be traversed in cool, matter-of-fact style, however ludicrously incorrect the offending theorist may be. It is not an uncommon thing, as any one of experience will bear out, for intervals of months and years to elapse between the exposure and development of silver bromide plates. Many of us may modestly claim to possess adequate facilities for confirming or confuting the practical value of the continuation theory. Without indulging in a multiplication of adverse evidence, it can be alleged quite freely that where the trial development of a few plates leads to large numbers being placed aside for development at a future year or month, the guiding qualities of the negatives eventually obtained differs in no visible manner from those developed shortly after exposure. If the continuation theory holds water, the plates known to be correctly exposed should be found to be overdone; those under-exposed, to have acquired the requisite ripeness; and so on. Again, where large numbers of plates are exposed, and a few developed immediately afterwards, that exhibit signs of being generally under-done, the remainder, which are reasonably considered as being in error as regards exposure, should, after the best part of a year, "continue" to the proper, or, at least, an improved degree of reduction. Alas! for continuation; they are as badly under-exposed as the trials of the last year. In fine, the cream of experience is overwhelmingly fatal to the probability of light possessing this extraordinary property, save in a practically inconceivable degree. It has never before, I believe, been suggested that the haloid salts of silver are liable under any circumstances to reduction in the absence of the active agent; if operative light could be stored up at will, the gardeners would not be alone in their rejoicings.

The misconception may have arisen from inadvertently confusing with the properties of the silver salts the continuing action of development in the dark, which is a characteristic of a certain platinum positive method; but here the compound that is to yield the image is in intimate union with its reducer, which completes the work begun by light—if moisture be present. Or it may be inspired by the fact that for a long time there was an idea that the exposure necessary to produce an autotype-carbon print might be largely curtailed by placing the print itself in the dark, the printing gradually continued, and on development, after some hours, the picture was found fully printed. But this continuing action was afterwards demonstrated to be due to the presence of moisture in the atmosphere. I think there is ample justification for disputing that any measurably appreciable alteration takes place in the undeveloped silver image between the time of exposure and that of development; and so long as it can be confidently felt that exposed plates may be kept for months, even years, without the sub-salt undergoing further reduction through an assumed storage of light-energy in the film, it would be bootless to formulate a more scientific anathema for this pretty little photographic heresy.

THOMAS BEDDING.

COLOURED PHOTOGRAPHS.

VII.

In my last paper I set down for consideration the merits, demerits, and other qualities of Chinese white, raw sienna, Indian yellow, light red, and Venetian red. We can now proceed with the other colours.

Vermilion.—I have remarked in this colour a vast variety of shades as produced by the various makers. Indeed, they may be said to vary in hue to such an extent as to embrace a range from the deep reds of a crimson character to the paler ones of scarlet and orange. In chemical composition they may be said to be practically the same, and consist of sulphide of mercury. The "vermillion" of water colours, when used without any qualifying word, such as scarlet, orange, &c., may be said to denote the rather deep and crimson-hued variety. In its best form it is a very permanent pigment. Some believe that it blackens in time, as evidenced in some of the very old illuminations, but I do not think this change at all attributable to any chemical decomposition.

Sulphide of mercury is found to exist in two very different modifications, the one red and the other black. As far as chemists have discovered, these two modifications are supposed to possess the same identical chemical composition, and it has been suggested that this difference of colour is simply the result of the different arrangement of their "molecules" or ultimate particles. We have no proof, however, that the old illuminators, whose work in time has become so blackened, had been in the habit of employing the *pure* pigment.

The modern product, when pure, has a very good reputation as regards its permanence, and in *oil colours* this quality is admitted on all hands, and I think with every degree of justice. There is, however, in water colour, a difference of opinion on this point, as the results of experiments have shown, but I am of opinion, and I don't stand alone, that a great deal depends both upon the manufacture of the pigment and also upon the medium with which the colour may have been mixed. One or two authorities, such as Mr. Simpson and Professor Hartley, have declared, after putting it to severe tests, that vermillion deserves to be considered a permanent colour. These tests have embraced its power of endurance as tried by time, as well as by exposure to violent sunshine. On the other hand, however, Professor Rood has declared that it has become darker and also of a brownish hue after exposure to strong sunlight for three and a half months.

Vermillion possesses great opacity, and does not flow very well. When used in quantity, it is rather difficult to handle, as it shows an extraordinary disposition to wash up; still, when skilfully used, it is a most useful pigment. It has a tendency also to separate itself from other colours with which it may be mixed. This is caused by the fact that it is a very heavy colour, and on this account should, when possible, be used in conjunction with the heavier colours. It is not affected by atmospheric influences.

Mixed with pink madder or rose madder, it produces a very fine tint for the carnations of the flesh.

Pink Madder and Rose Madder.—These colours, although at one time somewhat different, may be considered nowadays to be identical, both as regards hue and its uses. They are most delicate carnations, and are in great favour on account of their very superior permanency. They are much clearer and more delicate in their *lighter* washes than either crimson, lake, or carmine, but of course lack their density. They are of a beautiful rose tint, inclining neither to crimson nor scarlet. Its "*wash*" is its great virtue, and I think I may safely say that rose madder affords us the most perfect carnation that is known. It is conceded that years of exposure to the ordinary diffused daylight will have little or no effect upon it, but if exposed to the violent and prolonged action of sunlight it will lose considerably in intensity, and tend more to a purple hue.

Indian Red.—It may be said to resemble light red and Venetian red, both in its chemical constitution and its absolute permanence. There is a vast difference, however, in its hue. It is a purplish red colour of considerable power, and is a most excellent colour for the shadows of the flesh, either alone or in combination with blue.

Genuine Indian red is a natural earth, mostly found in Persia and parts of India, notably Bengal, and is particularly valued for its purple hue, and for the beautiful clearness of its tints. This colour, however, is now replaced by *artificial* Indian red, and which is an exceedingly good imitation. Notwithstanding that Indian red is looked upon as a most durable pigment in itself, water-colour painters are almost universally of opinion that it helps the decomposition of the more delicate colours when mixed with them. Indeed, the action of the *genuine* Indian red upon indigo in this regard is a matter of notoriety. Many of our best authorities, however, hold that the artificial varieties of this colour (Indian red) are entirely neutral as regards its action on indigo. This is Professor Church's opinion on the subject, and I believe Mr. W. J. Winsor, who has made exhaustive experiments on this point, backs him up. Such evidence as this I feel sure we may take as conclusive on the question.

Brown Madder.—This is a most beautiful colour, and as useful as it is beautiful. It may be described as a very rich, transparent, *lakey*, russet brown. By its use the richest descriptions of shadows may be obtained when applied in a fair degree of strength, while its paler tints exhibit extreme delicacy. Combined with blue, it makes a delicate grey for the flesh, or soft tint for the shadows on the face, &c. It will be found most useful, too, for many of the darkest touches in the flesh. When the draperies are red, they are often too glaring and attractive; brown madder may be used in their dark shadows and elsewhere to lower the general tone and produce a feeling of harmony. It is a lake prepared from the madder root and possessing great transparency and depth of colour. It is pleasant and easy to work, and so useful for shadows, &c., as to be almost indispensable to the water-colour artist. Exposed to ordinary daylight this colour may be considered practically permanent, but if exposed to violent sunshine will be found to be visibly affected by it. Indeed, if exposed to the action of direct sunshine I think it will be found to be the least permanent of all the madders.

Cobalt Blue.—This is a most useful colour, is possessed of sufficient brightness, is permanent, and washes well. It is a fine sky-blue colour, and in water colours the very best pigment for producing the silvery

tints and pearly greys on the flesh. It will also represent the blue tints, and, mixed with Indian red, will produce the shadow colour for flesh. By artificial light it partakes somewhat of a purplish tint, but this in the flesh is not materially perceptible.

This colour is prepared artificially by calcining a combination of alumina and basic phosphate of cobalt. It is more or less a modern colour, having been discovered by a Frenchman, M. Thenhard, at the beginning of this century. Having discovered this most beautiful colour he should have changed his name, as he could not have been *then hard* up for a blue. Cobalt blue has not the depth and transparency of the genuine ultramarine, but washes better and is more easy in its general use. The most perfect examples of this pigment are of a beautiful, rich azure colour. Although proof against the most severe exposure to strong light, cobalt is apt to be considerably influenced by an impure atmosphere, becoming greener in hue.

Burnt Sienna.—It may be described as an orange of a very rich and transparent brown or russet hue. It is a most useful colour, and besides being invaluable for its many beautiful combinations with other colours, may be very effectively employed in painting warm complexion. Besides this it is useful in some of the ordinary flesh tints. It is most useful to depict the shadow tints of amber-coloured draperies. I have known it employed for the dark shadows of gold trinkets with very striking effect. In the greens of landscape backgrounds it will prove valuable, and in combination with indigo forms an excellent colour for green backgrounds.

Burnt sienna is simply raw sienna calcined, is extremely permanent, and may be classed as one of our most generally useful of water colours.

Vandyke Brown.—This is a bituminous earth of a very rich and transparent hue. A very valuable colour, but suffering from the bad habit, a desire to "work up." Whenever it is necessary to lay a great body of this colour, I think the moist will be found better than the cake. A very fine, warm, and transparent tint, and one much used as a warm shadow colour, is formed by the judicious mixing of vandyke brown and lake.

This colour is produced from a bituminous ochre: it is a fine, deep, and semi-transparent brown. The very best examples of this colour come from Cassel. It varies considerably in hue, and forms a subject for likely discussion as regards its permanence. Under normal conditions it is in all probability durable, but, most decidedly, exposed to sunlight it fades and gradually becomes greyer in colour.

The foregoing are the colours most useful and mostly used in the painting of flesh. There are, however, other colours which with them enable us to do justice to the other portions of our picture besides the figure. The production of a harmonious background is quite half the picture, and much of our success will depend upon our knowledge how to do it and what colours we should employ. In addition to those above mentioned, the following will be found most useful:—Gamboge, yellow ochre, sepia, lake, carmine, French ultramarine, smalt, indigo, Prussian blue.

Gamboge.—This is a fine yellow colour, somewhat inclining to green. It is easy to work, flowing well, and the resin which it contains forms a kind of varnish, which helps considerably in preserving its colour. Useful at times for draperies.

It is a kind of gum resin which comes from Ceylon, is a bright, pale, transparent yellow, and much used in water colour. I do not incline much to its use as it has no great depth, and in deep touches seems to shine, producing anything but a pleasant effect, suggesting almost a brown. Exposure to sunlight will considerably weaken gamboge; but in ordinary daylight I have reason to believe that it will stand uninjured by any serious alteration for years. Although put down as fugitive itself, it has the desirable quality, when used as a glaze, of being able to preserve or protect the most delicate pigments. For this reason I must hesitate to say too much against it—still I cannot recommend its general use.

Yellow Ochre.—This is a very useful colour for producing atmospheric effects, as it seems to possess certain qualities of light which render it most effective for skies, &c. It is sometimes used in flesh, but for this purpose I prefer Roman ochre. For the local tint of light hair it is very useful, also for certain parts of landscape backgrounds. It is a very permanent pigment and works well.

It is a native earth, coloured by sesquioxide of iron; some of the finest quality is found, I believe, near Oxford. It is but a tolerably bright yellow, of inestimable value to the landscape painters, and irreproachable as to its reputation for steadiness. It is a vexed question as to the advisability of using it in combination with other colours, such as the lakes of cochineal or intense blue, for it is supposed to have an injurious effect upon them, therefore we may do well in avoiding such mixtures until the point be finally settled by those who understand these matters chemically better than we do.

Sepia.—Is a very valuable cool brown pigment. Its pale washes are extremely clear and transparent. It lends itself favourably to mixing with other colours, and by this means a great variety of valuable tints may be obtained. Mixed with indigo it may be used for distant trees, for a general shadow tint, for very light backgrounds, also for the shadings of white linen and white draperies. In combination with lake it forms a fine warm tint resembling somewhat brown madder, and with lake and indigo an excellent black will result. It is transparent, permanent, and works well. Indeed, it may be said to be the best washing pigment in an artist's water-colour box.

It is obtained from a secretion of the cuttle-fish, *Sepia Officinalis*, is a very powerful, dusky brown of finest texture. If kept from very strong light it may be considered durable, but if exposed to sunshine will fade perceptibly. REDMOND BARRETT.

THE PROPERTIES OF ALLOTROPIC SILVER.

THE three forms of allotropic silver which were described in the June number of this JOURNAL—the blue soluble and the blue and the yellow insoluble—are not to be understood as the only forms which exist, but as the best marked only. The substance is protean, and exhibits other modifications not yet studied. No other metal than silver appears to be capable of assuming such a remarkable variety of appearances. Every colour is represented. I have obtained metallic silver blue, green (many shades of both), red, yellow, and purple. In enumerating these colours I do not refer to interference colours produced superficially by reagents, also wonderfully brilliant, but to body colours. As a single instance of colouration the following may be mentioned. I recently obtained a solution of allotropic silver of an intense yellow-brown. A little solution of disodic phosphate changed this to bright scarlet (like Biberich scarlet), presently decolorising with formation of a purple precipitate. Washed on a filter this changed to bluish green. The colours I have met with in this investigation can only be compared with the coal-tar products, of which one is constantly reminded by their vividness and intense colorific power.

Two of the insoluble forms of allotropic silver, the gold-coloured and the blue, show in many respects a close relationship and almost identical reactions. There are other respects in which they differ strikingly, and amongst these instability. Blue allotropic silver (dark red whilst moist, becoming blue in drying), is very stable. It may be exposed for weeks in a moist state on a filter, or be placed in a pasty condition in a corked vial, and so kept moist for months without alteration.

The gold-coloured form, on the contrary, tends constantly to revert to ordinary silver. This is especially the case whilst it is moist, so that from the time of its formation it must be separated from its mother water, and washed as rapidly as possible, otherwise it loses its brilliancy and purity of colour, and changes to a dark, dull, grey form of normal silver. On the filter its proper colour is pure black, with a sort of yellow shimmer (the gold colour appearing as it dries), often, especially if allowed to become uncovered by the water during washing, it will change superficially to grey. But if the washing is done rapidly, with the aid of a filter pump and a pressure of four or five inches of mercury, the allotropic silver obtained, when allowed to dry in lumps, or brushed over paper or glass, is at least equal to pure gold in colour and in brilliancy. With the blue powder such precautions are wholly superfluous.

Of the facility with which the gold-coloured form is converted into normal silver, I have recently had a somewhat singular proof. I brought with me to my summer home a number of specimens in tubes, some recently prepared, some dating back as far as ten and a half years, together with other tubes containing specimens of white silver spontaneously formed from the gold-coloured. On opening the box no tubes of gold-coloured silver were to be found; all had changed to white. But the same box contained pieces of paper and of glass on which the same material had been extended; these were wholly unchanged, and had preserved the gold colour perfectly. Apparently the explanation was this—the mere vibration caused by the jarring of a journey of six hundred miles by rail and steamboat had had no effect in changing the molecular form, but the material contained in the partly filled tubes had been also subjected to friction of pieces moved over each other, and this had caused the change. To verify this explanation I prepared fresh material, filled three similar tubes, each one-quarter full, but in one forced in cotton wool very tightly to prevent frictional motion. These tubes were packed in a small box and sent over two thousand four hundred miles of railway. The tubes with loose material came back much altered. One was nearly white, and, as the change has been set up, will probably in a few days be entirely so; another with loose material was also changed, but not as much as the first mentioned. The tube filled up with cotton came back unaltered, so that continued friction of pieces sliding over each other will cause a change to take place in a few days, which otherwise might have required years, or might not have occurred at all. The permanency of this substance is greatly influenced by moisture, so that

* When well washed, this form can also be preserved for a time in the moist condition in a corked vial, as I have lately found.

† Has since become so.

when simply air dried before placing it in tubes it is less permanent than when dried at 70° or 80° C. in a stove. Tubes placed in the same box containing the blue form remained unaffected by the motion, though only partly filled and allowed to move freely.

When gold-coloured allotropic silver is gently heated in a test tube it undergoes a remarkable change in cohesion. Before heating, it is brittle and easily reduced to fine powder. After heating, it has greatly increased in toughness, and cannot be pulverised at all.

Both the gold-yellow and the blue forms resemble normal silver in disengaging oxygen from hydrogen peroxide. These two forms, though differing so much in colour and stability, and differing also in specific gravity, and in their mode of formation, have many properties in common, not possessed by ordinary silver, and differentiating them strongly from it. They show a vastly greater sensitiveness to re-agents, and are also sensitive to light. The ability to form perfect metallic mirrors by being simply brushed in the pasty condition over glass was mentioned in a previous paper.

Many substances which react little, if at all, with ordinary silver, attack the gold-coloured and the blue allotropic silver with production of very beautiful colours due to the formation of thin films and resulting interference of two reflected rays. In my previous papers I called this the "halogen reaction," because first obtained by the action of substances which easily parted with a halogen. But I have since found that many other reagents will produce the same or similar effects. These are:—

Sulphides.—Paper brushed over with either the gold, the copper-coloured, or the bluish-green substance exposed to the vapour of ammonium sulphide, or immersed in a dilute solution of it, assume beautiful hues, though less brilliant than those obtained in some other ways.

Potassium Permanganate in dilute solution produces blue, red, and green colours.

Potassium Ferricyanide in moderately strong solution gradually attacks allotropic silver with production of splendid blue, purple, and green coloration.

Phosphorous Acid produces gradually a rather dull coloration.

The colour reaction is produced finely by substances which readily part with a halogen—such as ferric and cupric chlorides, sodium hypochlorite, hydrochloric acid to which potassium bichromate has been added—and by corresponding bromine and iodine compounds. In some earlier experiments I obtained effects of the same sort, but in much weaker degree, with alkaline haloids. But with purer products the results have been different. There is at first some darkening, but no true colour reaction, and the allotropic silver appears to be gradually converted into normal, so that it is no longer capable of giving the brilliant colour reaction with potassium ferricyanide, but, like normal silver, takes a pale and faint coloration only.

The perchlorides of platinum, gold, and tin, do not give the colour reaction, though by analogy one would expect that they should, since they can lose chlorine with formation of a lower chloride.

Action of Light.—In a previous paper was mentioned the remarkable fact that the gold and copper-coloured forms of allotropic silver can be converted first into yellow, and finally into white, normal silver by the continued action of light. The earlier specimens of the blue form became brown by exposure, but purer ones since obtained are likewise converted into yellow by exposure, becoming continually lighter as the action is continued. The conversion from the darker shades to a bright yellow, with full metallic lustre, is very easy, but when the previous paper was written I had been only able to obtain the white by keeping the paper on which the silver was coated moist by a wet pad, and by exposing for five or six days. Since then I have obtained the gold-coloured silver in a more sensitive form, giving a perfectly white product by exposure dry for half that time.

The white silver thus obtained has all the character of ordinary silver, and does not show the colour reaction with ferric and cupric chloride, potassium, ferricyanide, &c. Just in proportion to the exposure to light the ability to give this colour reaction diminishes, so that after a day's exposure, when the exposed part has become bright yellow, the colour reagents scarcely affect this yellow, whilst the protected part becomes intense blue, purple, or green. In this way it is easy to observe the gradual effect of light as it changes the allotropic silver, finally converting it into what resembles in every way and is undoubtedly ordinary silver.

—*American Journal of Science* for September.

M. CAREY LEA.

THROUGH JAPAN WITH A CAMERA.

CHAPTER XII.—CONCLUSION—A WORD ON JAPANESE ART.

I would like to say a great deal about Japanese art, or rather I wish that I were qualified to do so, because I have been deeply impressed by it. One thing, that what I have seen in this country has convinced me of is, that at home there is an utterly erroneous idea of what art is at all: the idea held by the vulgar multitude, at any rate—of whom I count myself one—that it consists in picture making, and statue making, and analogous performances, appears to me now to be very absurd.

I conceive that art which is confined to one class of a people, and extends to only one class of subject, is not true art, and that art in a whole people, if it is to be in the least true, must be spontaneous and unconscious, and that it must penetrate into all the works, of even the meanest, of the people. This is greatly the case in Japan.

The commonest thing that is made or used has a grace and beauty about it that is quite wanting in things for common use at home. I am struck with this much more in the case of quite cheap things for every-day use than in that of the more elaborate articles that commonly find their way to England. Amongst a set of common Japanese cups, saucers, and tea-pots, the whole lot—costing, perhaps, a shilling a-piece—of English earthenware looks positively barbarous; but a single Japanese cup will not look other than beautiful beside anything; and the same may be said of all the commonest things. A Saké bottle—the analogue of our decanter—which costs a penny or twopenny, would be an ornament anywhere. In the poorest houses, things that we would never dream of using—common rough bits of wood and stone—are used, and are disposed in such a manner that shows a true feeling for what is beautiful. The drawing of the Japanese is notoriously lacking in perspective, and I must admit that I do not vastly admire the more ambitious attempts, but I think the very common drawing that is used for decorating even the poorer houses is often perfect. A few strokes—made with a brush and black colour—indicate a flower or a gracefully bending plant, and one could not conceive that a line could be altered by the distance of a hair's breadth and show any improvement. These things are done not by professed artists, but merely by handicraftsmen.

I believe that all this results greatly from the absence of anything corresponding to the system of wholesale manufacture that we have. The Japanese are not, as I have already said, a mechanical people, and have naturally no idea of all the methods that we have, by division of labour, the use of machinery, and so forth, of turning out a vast number of articles. Every little thing is made, from beginning to end, by one workman, and, as a consequence, it contains, to a certain degree, a reflection of the individuality of the maker, without some of which, I imagine, no beauty is possible. In a certain sense every workman becomes an artist, and the thing must act and react. He is an artist in the sense of creating something that has some beauty in it; he becomes an artist in unconsciously learning to love that which is beautiful, and to hate that which is ugly.

It would almost seem as if unconsciousness were an essential part of such a feeling, for when a Japanese wakes up to the idea that he wishes to be decorative, he very frequently goes woefully astray, adopting, for example, the most wonderfully incongruous mixture of European ornaments—of a coarser, and often more gaudy type—with rather debased Japanese art; but I feel that I have got on a subject that I have really no right to talk upon, and that silence is the best thing for the present.

W. K. BURTON.

THE ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION, 1889.

(By a Special Correspondent.)

JUDGES' REPORT.

THE Judges have great pleasure in recording the continued success of the Photographic Department. They have noticed a slight falling off in the Professional Section this year, and great increase in the exhibits of the Amateur Section, the latter showing a marked improvement in several of the classes. They also notice the names of several new exhibitors in all sections of the departments, and many of the old exhibitors still keep to the front; especially noticeable is the name of Mr. H. P. Robinson, of Tunbridge Wells, whose productions have adorned the walls of the Exhibition for over a quarter of a century, and are always worth careful study. Mr. R. W. Robinson, his son, follows in his father's footsteps this year with a collection of *Artists at Home*, being most of the Royal Academicians taken at home in their own studios, which make an interesting series, about twenty-four in number. Mr. W. J. Byrne, of Richmond, whose works are hung this year on the platform in the Great Hall, are perfect as specimens of the art. Mr. W. W. Winter is also to the front again with some of his very fine work. The portrait studies of Mr. Protheroe, of Bristol, printed in platinum, are also fine specimens. Mr. F. W. Edwards takes the first award for landscape work. In the amateur section, Mr. Cembrano is represented by some exceedingly fine interiors in the Alhambra. Mr. A. K. Barnett, of Penzance, shows some very careful work, for which he receives a medal.

In lantern slides, Mr. Henry Little receives an award; also Mr. Dresser, for some very clever instantaneous pictures.

In the photographic appliance department, Mr. F. W. Hart takes the only award in the section for his patent magnesium flash lamps, the very best of their kind, as his specimens will show. The different exhibitors are dealt with as they appear in the catalogue.

PROFESSIONAL SECTION.

Mr. H. P. Robinson sends two composition pictures, viz., *Fisher Maidens* and *Lobster Boats*. To the latter has been awarded a second silver medal; it is rather smaller than some of this artist's works, but in

treatment it is very realistic. Mr. J. Milman Brown contributes four studies, the best of which is No. 753, *Declining Day*. Mr. J. P. Gibson is represented this year by several careful studies; *Heary* is a very artistic conception, and admirably treated. Mr. F. W. Dew sends several pictures, and the judges are of opinion they have seen some better work in former years. P. M. Law and Son show two pictures; *What is it?* shows considerable artistic taste. Mr. W. Winter, of Derby, takes an award, a second silver medal, for his charming portrait group, very tenderly and delicately treated, printed in sepia platinum. Mr. R. H. Lord shows two pictures, *Neddy's New Shoes* and *Try Again*, both genre pictures; the latter is by far the best. Mr. R. W. Robinson has apparently set himself a very difficult task, viz., photographing the principal of the Royal Academicians at home at work in their own studios, of which he sends about two dozen examples, and has been awarded a special first bronze medal. He also contributes several clever sketches well worthy of notice. Mr. Frank Hopps contributes some very good frost studies. Mr. H. Keene takes the award for his collection of interiors, viz., a first bronze medal. Mr. W. M. Harrison's chief exhibits are enlargements of local people, and instantaneous groups of Mr. Gladstone's visit to Falmouth. Messrs. Werner & Son have two large portrait studies taken direct, printed in platinum. Mr. T. Protheroe, of Bristol, has been awarded a first bronze medal for the best six pictures by the platinum process, portrait studies which are very soft and brilliant. Mr. W. Scorer shows a number of pictures, one or two showing a certain amount of artistic merit, and others not so good as they might be if they had been more carefully printed. Mr. F. Whaley's best exhibit is *Sunset on the Don*, being well and carefully treated. Mr. Frank Sutcliffe, of Whitby, contributes a subject well chosen, *Dinnertime*. Mr. W. J. Ankorn sends six pictures of the genre order, which have been carefully worked out, and humorous in style. Messrs. Itiley Bros., of Bradford, show a frame of lantern slides, and would look far better if they were of a warmer tone. Mr. John Pike sends two pictures, interiors. Mr. F. W. Edwards takes the first silver medal for the best landscape in the Exhibition, which is of large dimensions, printed in platinum; it is a marvellous production. There are several others of different style, and all of a very high order. Mr. J. W. Byrne, as usual, is well to the front with his well-known portrait studies, and takes a first award, viz., a first silver medal, for a large direct portrait of W. Backwell, Esq., being one of the most perfect pictures of its kind; there are several other pictures by the same artist of almost equal merit. A hunting group, by Messrs. Chenall & Sons, is highly commended, and must have been a rather difficult subject to treat.

AMATEUR SECTION.

Mr. W. H. Kitchen exhibits several pictures of animals of the Zoo order, which show careful manipulation. Home portraiture by flash light is well represented by Mr. W. Taverner. Mr. A. Dresser sends for exhibition a goodly number of works, especially in the instantaneous class, some very clever work of a dog jumping. To No. 911 has been awarded a second bronze medal; the same gentleman also contributes a collection of lantern slides of animals in the Zoo, and a great deal of beauty is lost by their being printed too black; there are several other admirable pictures by the same gentleman—*On Duty*, our *Couteguard*—being the best. Mr. A. K. Barnett, of Penzance, shows a varied collection, and takes the medal for the best landscape in the section, viz., a first bronze medal for No. 861. Mr. Roscoe shows a frame of very artistic studies. Mr. Brewer contributes some very creditable work. The Rev. H. B. Hare has been awarded a second bronze medal for No. 921, being a very artistic production; there are several others, showing very great taste and skill. *An Old Salt*, by Mr. J. E. Brightman, highly commended for good manipulation; other work by the same gentleman shows great taste. The Rev. F. C. Lambert, Mr. S. Holgrove, and Mr. McCulack contribute. Mr. Henry Little sends a frame of lantern slides: instantaneous subjects, horses steepchasing, swans, &c., being the most perfect of their kind, and are of good tone; a first bronze medal has been awarded. Mr. F. C. Cembrano sends a very fine collection of interiors of the Alhambra, printed in platinum, being soft, delicate, and brilliant, and as near perfection as possible; to these have been awarded a first bronze medal. Mr. H. Murray, Mr. F. W. Lomer, and Mr. Arthur Carnell, exhibit some fairly good productions. Mr. M. E. Austin forwards some very clever and artistic genre pictures; to No. 972, *Any one at Home*, has been awarded a first bronze medal, the difficulty to be decided as to which was the best picture of this gentleman's work, all being so exceedingly fine. Mr. W. H. Hooton's works show careful study. Miss E. L. Hare is highly commended for a frame of lantern slides, and would have done more justice to the negatives had they not been printed so black and hard. C. S. Roe sends two pictures. Mr. Frank Howard contributes some very soft and delicate studies full of atmosphere. Mr. Ernest Beringer contributes one picture, *A Cool Retreat*. Mr. E. Brigleman sends a frame of lantern slides, printed evidently by a mechanical process, of various tones, which are very effective and fanciful. A set of lantern slides, by J. M. Harding, which are too heavily printed to give the best results on the screen. Mr. H. P. Taglietierro sends a photograph of a print, *A Favourite Spring*. Mr. Alfred Strielitz, of Berlin, contributes a portfolio of prints, portrait and landscape, which the Judges highly commend. Major J. D. Lysaght is represented by a frame of small sketches in Cork and Queenstown, which are little gems in their way.

PHOTOGRAPHIC APPLIANCES.

Mr. F. W. Hart, of Kingsland, London, shows several forms of his patent magnesium flash lamps, and also a good collection of pictures taken by their aid, of a very high order, some being 12 x 10 inches fully exposed, and well merit the award the Judges have given them, viz., a second silver medal. The same exhibitor also shows some very good racks for washing and draining plates. Mr. W. Scorer, of Havant, sends two cameras, one a parallel bellows body, and the other conical in form; they are rather of a complicated order, which, in the opinion of the Judges, are rather against them than otherwise. A photographic electric dark-room lamp, by Messrs. Cathcart & Peto, of London, is an exceedingly portable and useful arrangement, which the Judges highly commend.

PHOTOGRAPHY BY FLASH LIGHT.

Mr. F. W. Hart, F.C.S., delivered a lecture, with experiments, on "Magnesium and its uses," the Right Hon. Leonard Courtney, M.P., the President, occupying the chair. The lecturer remarked that eighty-one years ago Sir Humphry Davy was investigating the action of electric force, and succeeded by its aid in releasing magnesium from that old familiar medicine, Epsom salts. Bunsen in our own times was the first to improve on the electric decomposition of alkalies and earths, but his process was not a commercial success. Many minds were set to work to solve the problem, how to obtain the earth metals economically, the two most important being aluminium and magnesium, each profusely abundant in the crust of the earth. The clay under our feet points to the probability that aluminium takes precedence of all other metals for quantity. It is about five times lighter than brass, and less than double the weight of water; when untarnished it is beautifully white, almost rivaling silver, and upon being burnt gives a brilliant and smokeless flame. Some years ago Roscoe and Bunsen found that whilst the sun was about 625 times more brilliant than ignited magnesium, its power for producing photographic effects was only about 36 times as great; so that it was only necessary to increase the volume of light 56 times to rival the sun in the rapidity with which photographic results can be obtained, and Mr. Hart showed that this was not at all difficult by his cleverly devised lamps. Photographs of children at play were shown, produced at night in one-thirtieth of a second at eight feet distance from the source of light. By still further increasing the volume of light by more lamps, Mr. Hart felt fully assured that there would be no difficulty in getting full exposures in one-hundredth of a second. In photographing with the magnesium light, the principal object should be to produce breadth of lighting, so as to produce as near as possible the effect of the parallel rays of daylight. In chemical analysis magnesium is a most valuable adjunct in the detection of poisons. For military and naval signalling Mr. Hart has invented an apparatus, easily carried in a knapsack, by which a soldier can communicate, by using the Morse system of long and short flashes, either direct or, if a hill intervenes, by reflections in the sky. Magnesium is also largely used in pyrotechnic displays. In conclusion, Mr. Hart called attention to a series of very beautiful home photographs produced by means of the flash light, life-like and pleasantly free from that stiffness inseparable from having your likeness taken. Mr. Lanyon suggested that by means of the flash light photographs of workings in mines and of the interiors of the pyramids could be obtained; and he mentioned that in America it was now used in detecting crime. A policeman entering an illegal drink shop took an instantaneous flash light photograph of the scene, and it was produced in evidence. Mr. Barnett promised a series of photographs next year of miners at work underground.

ROYAL CORNWALL POLYTECHNIC ART UNION.

The drawing for the prizes took place in the Polytechnic Hall on the evening of Friday, September 13th, with the following result:—

No. 451, 11, E. Kitto. 677, 51, The Right Hon. Lord St. Levan, M.P. 539, 31, Robert Fox. 150, 21, John Borlase. 626, 11, The Right Hon. Leonard Courtney, M.P. 749, 101, Mrs. Wilson. 48, 101, Wm. Norton. 279, 71, Oscar Gutman. 264, 21, Miss Stevens. 664, 11, N. Lanyon. 5, 31, Mrs. Sharpe. 218, 11, J. Haye. 551, 11, Robert Fox. 281, 21, A. Latchmore.

The winners are allowed to select a picture to the amount of the prize in the Professional Fine Art Section, and also in the Professional Photographic Section.

BRITISH ASSOCIATION.

SECTION A.—(MATHEMATICS AND PHYSICS.)

[Opening Address by Captain W. de W. Abney, C.B., R.E., F.R.S., F.R.A.S., President of the Section.]

THE occupant of this chair has a difficult task to perform, should he attempt to address himself to all the various subjects with which this Section is supposed to deal. I find that it has very often been the custom that some one branch of science should be touched upon by the President, and I shall, as far as in me lies, follow this procedure.

This year is the jubilee of the practical introduction of photography by Daguerre and Fox Talbot, and I have thought I might venture to take up your time with a few remarks on the effect of light on matter. I am not going into the history of photography, nor to record the rivalries that have existed in regard to the various discoveries that have been made in it. A brand-new history of photography, I dare say, would be interesting, but I am not the person to write one; and I would refer those who desire information as to facts and dates to histories which already exist. In foreign histories perhaps we English suffer from speaking and writing in a language which is not understood of the foreign people; and the credit of several discoveries is sometimes allotted to nationalities who have no claim to them. Be that as it may, I do not propose to correct these errors or to make any reclamations. I leave that to those whose leisure is greater than mine.

I have often asserted, and I again assert, that there should be no stimulus.

for the study of science to be compared to photography. Step by step, as it is pursued, there will be formed a desire for a knowledge of all physical science. Physics, chemistry, optics, and mathematics are all required to enable it to be studied as it should be studied; and it has the great advantage that experimental work is the very foundation of it, and results of some kind are always visible. I perhaps am taking an optimist view of the matter, seeing there are at least 25,000 living facts against my theory, and perhaps not one per cent. of them in its favour. I mean that there are at least 25,000 persons who take the photographs, and scarcely one per cent. who know or care anything of the "why or wherefore" of the processes, so far as theory is concerned. If we call photography an applied science, it certainly has a larger number who practise it, and probably fewer theorists, than any other.

He would be a very hardy man who would claim for Niepce, Daguerre, or Fox Talbot the discovery of photographic action on matter. The knowledge that such an action existed is probably as old as the fair-skinned races of mankind, who must have recognised the fact that light, and particularly sunlight, had a tanning action on the epidermis, and the women then, as now, no doubt took their precautions against it. As to what change the body acted upon by light underwent it need scarcely be said that nothing was known, and perhaps the first scientific experiment in this direction was made rather more than a hundred years ago by Scheele, the Swedish chemist, who found that when chloride of silver was exposed to light chlorine was given off. It was not till well in the forties that any special attention was given to the action that light had on a variety of different bodies; and then Sir John Herschel, Robert Hunt, Becquerel, Draper, and some few others carried out experiments which may be termed classical. Looking at the papers which Herschel published in the *Philosophical Transactions* and elsewhere, it is not too much to say that they teem with facts which support the grand principle that without the absorption of radiation no chemical action can take place on a body; in other words, we have in them experimental proofs of the law of the conservation of energy. Hunt's work, *Researches on Light*, is still a text-book to which scientific photographers refer, and one is sometimes amazed at the amount of experimental data which is placed at our disposal. The conclusions that Hunt drew from his experiments, however, must be taken with caution in the light of our present knowledge, for they are often vitiated by the idea which he firmly held, that radiant heat, light, and chemical action, or actinism, were each of them properties, instead of the effects, of radiation. Again, we have to be careful in taking seriously the experiments carried out with light of various colours when such colours were produced by absorbing media. It must be remembered that an appeal to a moderately pure spectrum is the only appeal which can be legitimately made as to the action of the various components of radiation, and even then the results must be carefully weighed before any definite conclusion can be drawn. No photographic result can be considered as final unless the experiments be varied under all the conditions which may possibly arise. Coloured media are dangerous as enabling trustworthy conclusions to be drawn, unless the characters of such media have been thoroughly well tested and the light they transmit has been measured. An impure spectrum is even more dangerous to rely upon, since the access of white light would be sure to vitiate the results.

Perhaps one of the most puzzling phenomena to be met with in photography is the fact that the range of photographic action is spread over so large a portion of the spectrum. The same difficulty, of course, is felt in the matter of absorption, since the one is dependent on the other. Absorption by a body we are accustomed, and, indeed, obliged by the law of the conservation of energy, to consider as due to the transference of the energy of the ether wave-motion to the molecules and atoms comprising the body by increasing the vibrations of one or both.

In the case where chemical action takes place we can scarcely doubt that it is the atoms which in a great measure take up the energy of the radiation falling on them, as chemical action is dependent on the liberation of one or more atoms from the molecule, whilst, when the swings of the molecules are increased in amplitude, we have a rise in temperature of the body. I shall confine the few remarks I shall make on this subject to the case of chemical action. The molecule of a silver salt, such as bromide of silver, chemists are wont to look upon as composed of a limited and equal number of atoms to form the molecule. When we place a thin slab of this material before the slit of the spectroscopic we find a total absorption in the violet and ultra-violet of the spectrum, and a partial absorption in the blue and green, and a diminishing absorption in the yellow and red. A photographic plate containing this same salt is acted upon in exactly the same localities and in the same relative degree as where the absorption takes place. Here, then, we have an example of, it may be, the vibrations of four atoms, one of which at least is isochronous, or partially so, with the waves composing a large part of the visible spectrum. The explanation of this is somewhat obscure. A mental picture, however, may help us. If we consider that, owing to the body acted upon being a solid, the oscillations of the molecules and atoms are confined to a limited space, it probably happens that between the times in which the atoms occupy, in regard to one another, the same relative positions, the component vibrations of, say, two of the atoms vary considerably in period. An example of what I mean is found in a pendulum formed of a bob and an elastic rod. If the bob be made to vibrate in the usual manner, and at the same time the elastic rod be elongated, it is manifest that we have a pendulum of ever-varying length. At each instant of time the period of vibration would differ from that at the next instant, if the oscillations were completed. It is manifest that increased amplitude would be given to the pendulum swings by a series of well-timed blows differing very largely in period; at the same time there would be positions of the pendulum in which some one series of well-timed blows would produce the greatest effect. In a somewhat similar manner we should imagine that the ethereal waves should produce increased amplitude in the swing of the atoms between very wide limits of period, and, further, that there should be one or more positions in the spectrum when a maximum effect is produced.* I would here remark that the shape of the curves of sensitiveness, when plotted

graphically, of the different salts of silver to the spectrum have a marked resemblance to the graphically drawn curves of the three colour-sensations of the normal eye, as determined by Clerk Maxwell. May not the reason for the form of the one be equally applicable for the other? I only throw this out as evidence, not conclusive indeed, that the colour-sensitiveness of the eye is more probably due to a photographic action on the sensitive retina than to a merely mechanical action. That this is the case I need scarcely say has several times been propounded before.

The ease with which a silver salt is decomposed is largely, if not quite, dependent on the presence of some body which will take up some of the atoms which are thrown off from it. For instance, in chloride of silver we have a beautiful example of the necessity of such a body. In the ordinary atmosphere the chloride is, of course, coloured by the action of light; but if it be carefully dried and purified, and placed in a good vacuum, it will remain uncoloured for years in the strongest sunlight. In this case the absence of air and moisture is sufficient to prevent its discolouring.

If in the vacuum, however, a drop of mercury be introduced, the colouration by light is set up. We have the chlorine liberated from the silver and combining with the mercury vapour, and a minute film of calomel formed on the sides of the vessel.

Delicate experiments show that not only is this absorbent almost necessary when the action of light is so strong or so prolonged that its effect is visible, but also when the exposure or intensity is so small that the effect is invisible and only to be found by development. The reason for this absorbent is not far to seek. If, for instance, silver chloride be exposed to light *in vacuo*, although the chlorine atoms may be swung off from the original molecule, yet they may only be swung off to a neighbouring molecule which has lost one of its chlorine atoms, and an interchange of atoms merely takes place. If, however, a chlorine absorbent be present which has a greater affinity for chlorine than has the silver chloride which has lost one of its atoms, then we may consider that the chlorine atoms will be on the average more absorbed by the absorbent than by the subchloride molecules. The distribution of the swung-off atoms between the absorbent and the subchloride will doubtless be directly proportional to their respective affinities for chlorine, and so for the other salts of silver. If this be so, then it will be seen that the greater the affinity of the absorbent for the halogen the more rapid will be the decomposition of the silver salt. This, then, points to the fact that if any increase in the sensitiveness of a silver salt is desired it will probably be brought about by mixing with it some stronger halogen absorbent than has yet been done.

The question as to what is the exact product of the decomposition of a silver salt by the action of light is one which has not as yet been fully answered. For my own part, I have my strong beliefs and my disbeliefs. I fully believe the first action of light to be a very simple one, though this simple action is masked by other actions taking place, due to the surroundings in which it takes place. The elimination of one atom from a molecule of a silver salt leaves the molecule in an unsatisfactory condition, and capable of taking up some fresh atom. It is this capacity which seemingly shrouds the first action of light, since when exposure is prolonged the molecules take up atoms of oxygen from the air or from the moisture in it. Carey Lea, of Philadelphia, has within the last three years given some interesting experiments on the composition of what he calls the photochloride of silver, which is the chloride coloured by light, and Professor Hodgkinson has also taken up the matter. The conclusions the former has drawn are, to my mind, scarcely yet to be accepted. According to the latter experimentalist the action of light on silver chloride is to form an oxidised subsalt. This can hardly be the case, except under certain conditions, since a coloured compound is obtained when the silver chloride is exposed in a liquid in which there is no oxygen present.

This colouration by light of the chloride of silver naturally leads our thoughts to the subject of photography in natural colours. The question is often asked when photography in natural colours will be discovered. Photography in natural colours not only has been discovered, but pictures in natural colours have been produced. I am not alluding to the pictures produced by manual work, and which have from time to time been foisted on a credulous public as being produced by the action of light itself, much to the damage of photography and usually of the so-called inventors. Roughly speaking, the method of producing the spectrum in its natural colours is to chlorinise a silver plate, expose it to white light till it assumes a violet colour, heat it till it becomes rather ruddy, and expose it to a bright spectrum. The spectrum colours are then impressed in their natural tints. Experiment has shown that these colours are due to an oxidised product being formed at the red end of the spectrum and a reduced product at the violet end. Photography in natural colours, however, is only interesting from a scientific point of view, and, so far as I can see, can never have a commercial value. A process to be useful must be one by which reproductions are quickly made; in other words, it must be a developing and not a printing process, and it must be taken in the camera, for any printing process requires not only a bright light but also a prolonged exposure. Now it can be conceived that in a substance which absorbs all the visible spectrum the molecules can be so shaken and sifted by the different rays that eventually they sort themselves into masses which reflect the particular rays by which they are shaken; but it is almost—I might say, quite—impossible to believe that when this sifting has only been commenced, as it would be in the short exposure to which a camera picture is submitted, the substance deposited to build up the image by purely chemical means would be so obliging as to deposit in that the particular size of particle which should give to the image the colour of the nucleus on which it was depositing. I am aware that in the early days of photography we heard a good deal about curious results that had been obtained in negatives, where red-brick houses were shown as red and the blue sky as bluish. The cause of these few coincidences is not hard to explain, and would be exactly the same as when the red-brick houses were shown as bluish and the sky as red in a negative. The records of the production of the latter negatives are naturally not abundant, since they would not attract much attention. I may repeat, then, that photography in natural colours by a printing-out process—by which I mean by the action of light alone—is not only possible, but has been done, but that the production of a negative in natural colours from which prints in natural colours might be produced appears, in the present

* The effect of perfect and nearly perfect synchronism of one oscillation upon another is also to be found exemplified in my *Treatise on Photography* ("Text-book of Science Series").

state of our knowledge, to be impossible. Supposing it were not impracticable, it would be unsatisfactory, as the light with which the picture was impressed would be very different from that in which it would be viewed. Artists are fully aware of this difficulty in painting, and take their precautions against it.

The nearest approach to success in producing coloured pictures by light alone is the method of taking three negatives of the same subject through different coloured glasses, complementary to the three colour-sensations which together give to the eye the sensations of white light. The method is open to objection on account of the impure colour of the glasses used. If a device could be adopted whereby only those three parts of the spectrum could be severally used which form the colour-sensations, the method would be more perfect than it is at present. Even then perfection could not be attained, owing to a defect which is inherent in photography, and which cannot be eliminated. This defect is the imperfect representation of gradation of tone. For instance, if we have a strip graduated from what we call black to white (it must be recollected that no tone can scientifically be called black, and none white) and photograph it, we shall find that in a print from the negative the darkness which is supposed to represent a grey of equal mixtures of black and white by no means does so; the black is not as black nor the white as white as the original. The cause of this untruthfulness in photography has occupied my attention for several years, and it has been by endeavour to find out some law which will give us the density of a silver deposit on a negative corresponding with the intensity of the light acting. I am glad to say that at the beginning of this year a law disclosed itself, and I find that the transparency of a silver deposit caused by development can be put into the form of the law of error.

This law can be scarcely empiric, though at first sight it appears that the manipulations in photography are so loose that it should be so. It is this very looseness, however, which shows that the law is applicable, since in all cases I have tried it is obeyed. That there are theoretical difficulties cannot be denied, but it is believed that strictly theoretical reasoning will eventually reconcile theory with observation.

This want of truth in photography in rendering gradation, then, puts it out of the range of possibility that photography in natural colours can ever be exact, or that the three-negatives system can ever get over the difficulty.

(To be concluded.)

Our Editorial Table.

THE WATERLOO PLATE.

THE "Waterloo" is a plate of Belgian manufacture, which is issued in two classes, viz., those for water development and those for development by the usual means. In the former the plate is coated on the back with a pellicle, soluble in water, in which hydroquinone forms a leading ingredient. When an exposed plate is placed in a dish containing the requisite quantity of water the backing soon dissolves, and the image appears and comes up of good quality. This, at any rate, was the result in our hands. The ordinary plates, or those which must be developed in the usual way, possess, like the others, a real sensitiveness, and give an excellent quality of negative. Messrs. C. R. Bourn & Co., 43, Eastcheap, are the agents for its sale.

VEVERS' TRADE CATALOGUE.

THE catalogue of Mr. C. C. Vevers, Leeds, exhibits a marked increase (compared with a previous one) in capacity and the variety of articles embraced therein, with a very considerable reduction in prices, more especially of his own manufactures. It being impossible for us here to enumerate even a portion of the many good things contained in this price list, we recommend our readers to procure it for themselves.

RECENT PATENTS.

PATENT COMPLETED.

IMPROVEMENTS IN PHOTO-LITHOGRAPHIC PRINTING AND TRANSFERS BY WHICH A RESULT EQUAL TO PHOTOGRAPHIC PRINTING CAN BE OBTAINED FROM STONE.

No. 12,307. HENRY RYDER and WILLIAM HENRY RYDER, 35, Vicar-lane, Bradford.—August 24, 1889.

HALF-TONE process by two separate negatives from photograph or from picture. Our claim is by using two separate negatives from photograph or picture printed in two separate printings from stone or block.

First, a screen (or negative) is got from a lined or stippled plate after a perfect negative has been secured; then a photograph or wash drawing is adjusted and focussed to the size required in the camera; then a wet plate is prepared and placed in dark slide with screen before it, then exposed in camera, the plate being then developed. The first negative is over-exposed, giving details in darker parts of the object; the second negative is under-exposed, only bearing the lighter parts of the photograph.

Points are then taken from the negatives on prepared photo-litho-transfer paper, and inked and developed ready for transferring to stone or zinc, or printed direct to zinc in bitumen or albumen, and etched on zinc for letterpress printing as well as for lithographic printing.

What is claimed is:—Two separate negatives combined in the production of our picture by two separate and distinct printings from stone or from block prepared for letterpress printing.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

SEPTEMBER 17.—Technical meeting.—Mr. Friese Greene in the chair.

The CHAIRMAN showed some photographs printed by development on gelatin-bromide emulsion spread upon sheets of white celluloid stamped into ornamental patterns with a space left plain for the portrait. There was, he pointed out, a certain unevenness in some of them that was due to irregular taking of the wood naphtha, which was necessary as a preliminary before coating.

Mr. T. BOLAS remarked that the naphtha had acted as a solvent to the camphor, and Mr. A. COWAN suggested that the naphtha should be rubbed on with a tuft instead.

Mr. J. A. HARRISON showed a photograph of a building in which the vertical lines were convergent, and a copy from it in which the distortion was corrected by having the original and the copy both slanted with respect to the optical axis of the lens.

A question was raised as to the best method of obtaining a photograph direct upon a blank basis. It was complained that glass positives were all more or less dingy, even if toned with mercury, and a member referred the question to an article that appeared some three years since, describing some experiments made in Vienna with a view to obtaining this result.

A member inquired whether a thin negative was not the best for producing a collotype.

Mr. BOLAS replied that it was so. A dense negative was very bad for the purpose.

The question of the hot *versus* the cold process of development for platinum printing was discussed, and the former method was considered by several speakers to be the better one.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 12.—Mr. E. Clifton in the chair.

A question was read:—"What is the best length of focus for a lens for a quarter-plate detective camera?"

Mr. F. KEHR considered from five and a half to six inches to be the best.

Mr. A. COWAN had an idea that a longer focus was desirable, so that it would not be necessary to go so close up to the object.

The CHAIRMAN and Mr. KEHR spoke of the necessity for adjusting focus when lenses of more than ordinary length of focus were used, and considered that the great objection to this was the difficulty of judging distances, assuming that the focussing was done by adjustment to a scale on the camera, and not by inspection of the ground glass. The Chairman, moreover, found that many got on well with detective cameras of quarter-plate size, but proved quite hopeless with a half-plate one. The short focus, and consequent absence of necessity for focussing, was doubtless an important element in the success of the Kodak camera. Some, however, failed with this instrument, from exposing on dark subjects such as were not fitted for detective work.

Mr. FRESHWATER had recently met with a gentleman who had taken nine hundred subjects on a tour with a Kodak, and he was surprised to see what a very small percentage of them turned out unsatisfactorily. They were as nice a lot as any he remembered to have seen.

The opal cards left by Mr. Friese Greene for experiments by the members of the Association were then distributed by ballot.

The subject of the comparative merits and disadvantages of different developers was then brought forward, and Mr. A. MACKIE, speaking of hydroquinone, said that he found it liable to develop very unequally.

The CHAIRMAN agreed with this view, and said that hydroquinone developed by jumps; the picture would suddenly begin to darken at one corner and go on rapidly at the finish. As to the new developing agent, eikonogen, he did not find the solution preserve the green colour that it had when freshly mixed.

Mr. W. E. DEBENHAM recommended the use for mixing of water that had been boiled and bottled, or used before getting quite cold. He found the solution keep well.

The CHAIRMAN said that the addition of hydrochloric acid to eikonogen solution changed the colour to a bright rose-pink; the further addition of soda in excess restored the green tint, and this change of colour might be repeated many times. As to the use of sulphites and meta-bisulphites with pyro solutions, he found that one part of meta-bisulphite would suffice to keep six parts of pyro.

Mr. MACKIE used sulphite of soda neutralised with meta-bisulphite of potash, for which purpose he found one part of the latter generally required for three of the former.

A question was read as to whether ferricyanide solution would keep in the light; and the opinion prevailed that in the ordinary dark room it would not undergo any practically deleterious change.

It was announced that during the coming winter season there would be lantern exhibitions on the second Thursday in the month, and that a series of papers or lectures was intended to be given on the fourth Thursdays. Visitors would be welcomed to both.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

SEPTEMBER 9.—Mr. J. Saville in the chair.

Mr. A. Le Vierge was elected a member.

Mr. H. BECKETT, in toning prints, used the ordinary acetate toning bath, but one made with borax was found to be decidedly the quicker of the two, although the resulting tones when finished were found to be equal.

Some spoilt prints exhibited by Mr. Cherry elicited discussion as to the reason of the defects; it was ultimately decided, however, that the spots apparent in them were due to toning in a *papier-mâché* dish which had been used for fixing.

Subject for next meeting, September 23, *Transferotype*; demonstration by Mr. Bishop. Visitors invited.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 12.—The President in the chair.

Messrs. W. H. Hunt, Mus. Doc., and H. B. Mellor were elected members.

Mr. C. B. Reader reported on the Knowsley excursion, which consisted of about thirty members and friends.

The President presented his prize medal, which had been awarded by the Judges to the Hon. Secretary, J. L. Mackrell.

Mr. J. A. FORREST drew the members' attention to the great facility that now presented itself by the Association having its own library, which contained many books on photography, journals, &c., and urged the members to make use of the same. He also stated that, through the kindness of one of the lady members—Mrs. M. Webb—the Association had been presented with a very large box case, which was very acceptable and valuable in the way of keeping the Association things in.

Mr. Archer exhibited a box case, about two feet six inches long, containing lens, &c., for making slides by reduction from full plate.

Mr. P. H. PHILLIPS then read his paper on the *Optical Lantern*, with illustrations, which created great interest and instruction to all present, and we shall in next issue give a summary of the paper.

A lantern exhibition took place, with slides by the following members:—Messrs. Reader, Mackrell, Faltin, Noakes, and Mrs. M. Webb.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

SEPTEMBER 12.—Mr. W. J. Harrison (Vice-President) in the chair.

A letter was read from Mr. W. F. Kimberley, offering his dark room for the convenience of members at the excursion to Kenilworth on the 21st instant.

The HON. SECRETARY, as leader of the excursion to Dovedale, reported that a large number of members and friends travelled to Ashbourne by special train, fourteen cameras were carried, and one hundred and fifty-nine exposures made; and gave notice that the pictures for competition must be sent him not later than September 27, for transmission to the Judge appointed to make the award.

The CHAIRMAN, on calling upon Mr. E. H. Jaques (Vice-President) to give his paper on *Lantern Slide Making* [see page 617], remarked, Our optical lantern dates back to the early part of this century, when Lieutenant Drummond used a lime ball made incandescent for the purpose of signalling by night across distances exceeding fifty miles. The first transparent photographic positives on glass (lantern slides) were probably made by Langenheim, in the United States, about 1851; and soon afterwards what we may term the first really successful displays with the lantern on a large scale were shown at Manchester and Liverpool by Dancer. He had great pleasure in calling on Mr. Jaques, who they all knew had great experience in this branch of photography.

The lecturer was frequently applauded by the members, who thoroughly appreciated the lucid manner in which the subject was treated and the beautiful slides subsequently shown.

DERBY PHOTOGRAPHIC SOCIETY.

SEPTEMBER 10.

The Hon. Secretary showed some bronze medals sent by Mr. Restall, of Birmingham, which were excellent in design and finish.

Mr. Scotton handed round a number of silver prints from negatives taken during the Convention, which were much admired.

A discussion was then raised by Mr. Chadwick on *Halation, its Cause, &c.*, which was warmly entered into, and many unique suggestions were thrown out as probable preventatives.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

SEPTEMBER 13.—Outdoor meeting.—A most successful excursion was arranged to Matlock, seventeen members and friends attending. Having ferried over the river, the charming scenery of the Lovers' Walk engaged the attention of the tourists, the wooded river banks lending themselves readily in assisting picturesque composition. The party thereafter visited Willesley, the seat of Mr. F. Arkwright, and were here joined by a small but prominent deputation from the Derby Photographic Society. From here the party drove to the famous High Tor, and having duly paid homage to the historic old pile, packed up and returned, having thoroughly enjoyed what may be fairly considered the trip of the season. Forty-six plates were exposed by the members.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, September 25, 1889, will be on *Bromide Paper Printing*. Saturday outing at Earlsfield.

Correspondence.

Correspondents should never write on both sides of the paper.

NATURALISTIC PHOTOGRAPHY.

To the EDITOR.

SIR,—At last we begin to see blue water. I find we are all naturalistics; at least, I confess that I am one now that I know what naturalism is. I have been wanting a definition for years. Anything like a concise definition has been wanting up to the present time, for, as Bacon says, there be those who "count it a bondage to fix a Beeleefe; Affecting Freewill in Thinking, as well as in Acting. And though the Sects of Philosophers of that Kinde be gone, yet there remaine certaine discoursing Wits, which are of the same veines, though there be not so much Bloud in them, as was in those of the Ancients." At last we are favoured with the long-felt want by Mr. Davison, who tells us, in italics, that the naturalistic creed is, *Truth, and the best of everything*. Why, that is what I am always fighting for! "The best of everything" explains, among other things, why I try to provide myself with better models than haphazard chance would fling at me, which is one of Mr. Davison's accusations against me. That, also, is why I think a picture over before taking it, instead of after. I am always in search of truth.

"For truth has such a face, and such a mien,
As to be loved needs only to be seen."

And therein is the difficulty—how to see it; for no two men ever agree as to what is truth.

But Mr. Davison goes too far when he claims that "This differentiates it from the ordinary school, which, instead of considering exclusively the actual colouring, harmonies, tone, feeling, character of a subject, imparts what is termed imagination into the work, and treats much of the colouring, drawing, and selection from a consideration of theories or conventional ideas deduced from an analysis of the works of former successful painters."

We confess that we do not study harmonies, tone, &c., *exclusively*, as seems to be the boast of the naturalistics, but we *do* study these qualities, and try, in all humility, to add imagination, and to take advantage of the experience of the past. The difference between us seems to be this. The naturalistics want "severe truth;" we want what is so admirably expressed in Gray's well-known line, which seems to put it all into a nutshell—

"Truth severe, by fairy fiction dressed."

But what has puzzled me for some time past is this: What in the world is the use of all this disputing over terms? for that is nearly all it comes to; for we all love nature, and try to follow her lead according to our more or less imperfect lights.

"Some say, compared to Benoncini,
That Mynheer Handel's but a nimny;
Others aver that he to Handel
Is scarcely fit to hold a candle.
Strange all this difference should be
'Twixt Tweedledum and Tweedledee."

Let us, then, stop disputing, and be content with putting our theories into our work. We may even go further and show our results, for "Things seen are mightier than things heard."

I must thank Mr. Davison for the graceful courtesy with which his letter is written. There is only one word in it to which I could take any exception, and that must have been a naturalistic slip, so I will no further allude to it.—I am, yours, &c.,

H. P. ROBINSON.

Tunbridge Wells, September 16, 1889.

To the EDITOR.

SIR,—It is rather hard that Mr. Robinson should take that horn of my dilemma which was manifestly intended to be inapplicable, and then to hint at want of courtesy on my part. Nothing was further from my intention than to be rude to him or call him names, and in my turn I am quite ready to believe that his slightly undignified reference to "Mr. Graham" was due to a slip or a printer's error.

But as for my other alternative, which cannot be eluded, Mr. Robinson admits that for several years past he has been perfectly familiar with Dr. Emerson's pictures. Then what on earth did he mean by his extraordinary and sudden challenge, which was accompanied by the statement that "it would be only fair, *not only to myself*, but to photographers generally, that after so much excited theory the naturalistics should show us a little of the results when reduced to practice?"

It may be interesting hereafter to discover what amount of "long-patient study in the country" will enable any one, beside a naturalistic, to discover the difference between real dairymaids and ladies masquerading, but as far as I am concerned, and more especially after

Mr. Davison's admirable letter, the controversy must here end, nor would I have troubled you with this letter except to clear myself from a charge of discourtesy.—I am, yours, &c.,
GRAHAM BALFOUR.

To the Editor.

SIR,—There seems to have been plenty written on this subject, but no definite termination arrived at.

Mr. Balfour, in his letter of August 23, alludes to numerous painters having the detail obliterated, or nearly so. We will take, for instance, Rubens's *Christ being Crucified*. What would be the effect without the detail of the left-hand lowest corner, i.e., the expression of the three faces? Again, why does Jesus Christ form the attractive object? There is in this picture a simple lesson, viz., that we can attract the spectator's eye to any part of the picture without sacrificing the details.

Again, if an artist desires to give value to any part, he will place near it an object of different texture, but he will never destroy the detail of that object. This the portrait lens does, leaving as the result a hard-lined subject against a soft background, with the objects in a hazy atmosphere and obliterated detail, as if they were miles distant, though their size tells you different. A good rectilinear, in the hands of a good artist, will enable him to produce pictures without abusing nature to such an extent as is seen nowadays.—I am, yours, &c.,
H. VICTOR PAGE.

23, Cattell-road, Birmingham.

"MOON REFLECTIONS."

To the Editor.

SIR,—One evening last week, about nine p.m., the sky presenting a most beautiful appearance of mottled clouds slowly drifting over a bright moon, I was tempted to take out my camera and have a shot. Having never by night attempted anything of the sort before, I was naturally quite in the dark as to what exposure should be given; so lighting the flagrant weed, I sauntered up and down the lawn and determined to enjoy the delightful coolness of the hour so long as my cigar lasted, and then put on the cap again. This I found by my watch to be exactly twenty minutes; and though, of course, with this lengthened exposure I could not expect to get (with no counterbalancing movement) any passable definition of the moon itself, yet I must say I was surprised to find what a distance it must have travelled in this short time, the space on the plate occupying very nearly three-quarters of an inch. At the beginning of the exposure the moon was perfectly clear, but about midway it was overclouded, and consequently does not appear in the negative, while just at the end for two or three minutes all was bright again.

Now, Sir, I must own, alas! I am extremely deficient in knowledge as to the laws which govern the planetary system, but it occurred to me, could not some useful calculations be made by means of photography as to the relative measurements and distances of certain celestial bodies? Please remember with much misconfidence I only throw out this suggestion—it has most probably been thought of by yourself and many others before, and if it has, kind Mr. Editor, I humbly apologise and beg you to pardon my ignorance.—I am, yours, &c. (if it only be),—
A MARE'S NEAT.

P.S.—I shall be happy to send you the negative, or a print from it, if you wish me to do so.

[Yes; send a print.—Ed.]

CONVERTING A DEVELOPED IMAGE.

To the Editor.

SIR,—An unfixed developed positive consists of a positive image in metallic silver on a negative image of a silver salt; if the positive image be dissolved away, the remainder of the plate can be developed as a negative. This gives a means of producing an enlarged negative at one operation and without the loss of detail involved in making an intermediate positive. With collodion the process is easy. Can any of your readers say how it can be done with a gelatino-bromide plate? Captain Abney's method with a bichromate makes the plate too slow for enlarging. Dr. Eder says "mercury nitrate;" "mercuric per-nitrate" dissolves the silver, but attacks the unaltered bromide before the whole of the silver positive is gone. I cannot find that his second method of potassium iodide and potassium bromide has any effect on the silver positive. I suspect there is a misprint. Iodine in potassium iodide removes the positive, but leaves the negative image undevelopable; I presume it converts it into silver iodide. Could the silver bromide be protected from the iodine, iodine would answer perfectly.—I am, yours, &c.,
Foreign Office, September 17, 1889.
H. FARNALL.

"NOTES FROM NEWCASTLE."

To the Editor.

SIR,—Little as it may interest your readers, a few words of comment on the ill-natured remarks of your anonymous contributor agent the Northern Counties' Photographic Association seem indispensable. That

the Society has not made an effort to entertain Captain Abney during his visit to Newcastle is certainly to be regretted; but it is rather due to a perhaps needless modesty than to any want of respect for one who has probably done more than any other living scientist to elucidate the nature of photographic action. That the Society is at present a small one is largely owing to some petty personal quarrels of past times, in which, for aught I know, your contributor may have had his part; but thanks greatly to the energy of our present Hon. Secretary, Mr. E. G. Lee, it is by no means moribund, but living and growing.

The removal of the meetings to the Mosley-street Café, where the soothing fragrance of tobacco is not forbidden, has greatly improved their social character, and many of the discussions last winter were very interesting, while the lantern demonstration was, as usual, a great success. An effort will be made this winter to still further popularise the Society, and if your contributor, instead of sneering, will come forward with his suggestions for improvement, they will receive the consideration which they merit.—I am, yours, &c.,
HENRY R. PROCTER.

Tynemouth, September 15, 1889.

THE MISAPPLICATION OF LENSES.

To the Editor.

SIR,—Photographers will be very much interested in the proceedings of the Convention, especially with the papers read before the members. At all times the subject of lenses is of vital importance to us, therefore it is a pity that Mr. Thomas R. Dallmeyer did not discuss the most important point in his paper—large direct heads and enlargements.

As young photographers, we require to know the whole truth from our superiors in language clear, direct, and practical. Teaching that falls short of this is a waste of time, consequently we claim kinship with the Cornishmen who wanted to know the reason why. Ambiguity is not conducive to progress, and we hold that Mr. Dallmeyer's teaching with regard to the use of lenses is misty, theoretical, and unadapted for every-day use, and a careful examination of Mr. Dallmeyer's paper in your issue of August 23 will prove the truth of this assertion.

As a matter of fact, he says "that a direct large head, when taken under the most favourable circumstances—that is, with a lens of long focus—is undoubtedly much more pleasing than an enlarged small image."

Now this is apart from the real question raised, namely, distortion. The pleasing results are not gained with the lens, but with the printing process; direct printing is a different thing from accurate reproduction from life or a negative. And seeing we have failed to gather anything from Mr. Dallmeyer's paper to enlighten us with regard to the use of photographic lenses, we respectfully beg to lay before the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY the practical outcome of a few years' experience and close observation. With regard to the correct reproducing power of lenses for accuracy in portraiture, there is no lens can equal the ordinary rectilinear or symmetrical, next comes the ordinary single achromatic meniscus, and lastly the portrait lens. An enlarged head from a negative taken with a rectilinear or symmetrical lens cannot be approached for fidelity of reproduction.—I am, yours, &c.,
Madduff.

LARRY O'BROOM.

Exchange Column.

* No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, 12x10 camera or other photographic apparatus in exchange for semi-racer safety bicycle.—Address, GRAYSON, Photographer, Blackburn.

Wanted, THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1890 in exchange for Marlon's Guide to Photography.—Address, J. F. McKIE, 31, Sarah-street, Newcastle-upon-Tyne.

Will exchange limp canvas camera case (new), to carry camera and three dark slides, &c., 12x10, for background (interior or exterior).—Address, W. M., 64, Brunswick-avenue, Hull.

Wanted, complete photographic outfit and sundries in exchange for Singer's straight-steering Cripple tandem tricycle, cost 40l.—Address, WILLIAMS, Milton House, Ladywell, S.E.

Wanted to exchange a banjo, seven strings, machine head, nickel-plated hoop, for half-plate camera and slides.—Address, J. J. BAYFIELD, 5, Upper Hill-street, Richmond, S.W.

Will exchange whole-plate portrait lens (Derogy) for a whole-plate or 10x8 wide-angle doublet, or a half-plate "189 Instantograph" set.—Address, C. MURRAY, 3, Nightingale-terrace, Sutton, Surrey.

A Dallmeyer's rectilinear stereoscopic lens and a "New Stereographic" rapid portrait lens; wanted, a Ross' No. 2 portable symmetrical and a 5x4 wide-angle landscape lens.—Address, Lieut.-Colonel GERRARD, Westward Ho!

I will exchange for a good quarter-plate shutter, with pneumatic release, THE BRITISH JOURNAL OF PHOTOGRAPHY for 1887 and 1888, one bound (half calf).—Address, WILLIAM THOMPSON, 2, Gay's-terrace, Blue Bell Hill, Nottingham.

Answers to Correspondents.

* Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

W. G.—See reply to A. J. Coles.

H. A. WALL.—*Le Moniteur, L'Amateur, and Bulletin de la Société.*

W. CORNWELL.—The Company has been wound up and all the effects sold. They only realised about 170*l.* or 180*l.*

JAMES COLE.—Wray's quick-acting detective lens is not quite six inches in focus, but is sufficiently near it to answer your purpose.

A. A.—Send us an example of the failure; your account is too vague for us to indicate the cause. Are you sure the light of your dark room is safe?

INQUIRER.—1. Isochromatic and orthochromatic are synonymous terms as popularly applied to plates.—2. Better use a pale yellow screen for landscape work.

SETH.—If you copy any portion of the photograph, even if it be only for a lantern slide, you infringe the copyright and subject yourself to the consequences.

F. B.—While not worse than several pictures we have seen taken by a well-known "Naturalistic," we ourselves consider it unnatural in its badness. See what was said by us last week.

A. J. COLES.—Any of the French and German works on photography may be procured through a foreign bookseller. Messrs. Trübner, Ludgate-hill, will supply them to order. Give the title and publisher.

C. STEWART.—If the gold will not precipitate on the addition of a solution of sulphate of iron you may rest assured that the toning bath contains none of the precious metal; it has all been used up in toning the pictures.

W. H. C.—The lens appears to be a fairly good one, but there is little wonder that you did not get good pictures with it as the back glasses were put in wrongly. They are right now. The instrument is returned by Parcels Post, as requested.

SNAP SHOT.—The information you desire cannot be given in this column. In good light a single landscape lens of six inches focus will answer well, but if the light be dull it will be better to have a rapid doublet working with an aperture of *f*-6 to *f*-8.

F. J. L.—Neutralise the acid in the solution of chloride of platinum with carbonate of soda, then acidify with nitric acid in the proportion of one minim of acid to each grain of the platinum salt. This will make a very good toning solution.

A. JAX.—Primarily the fault proceeds from the plates. Occasionally some plates will show green fog when they are under-exposed and much forced in the development. If the plates were properly backed there should be no halation. Are you sure your defect is halation?

W. C. LONGMAN.—If the colour does not "take" evenly on albumen prints, wash the surface over with a very weak solution of prepared oxgall, which is supplied by the artists' colourmen. Sometimes licking the surface of the albumen with the tongue will overcome the difficulty.

C. J. E.—When the field of the lens is round, the best general sharpness is secured by focussing an object midway between the centre and margin. If it were quite flat, a characteristic possessed by no lens which is on the market, then it would be immaterial which point is focussed.

W. R. THOMPSON inquires what is the meaning of "triple nitrate of silver."—This is a term which is sometimes applied to nitrate of silver which has been crystallised three times. It is supposed to be purer than that which has only been crystallised once, or the recrystallised, which has been crystallised twice.

J. MOUNTFORT.—The matter is very easy of explanation. The plate was very much over-exposed, so that a reversed action of light was produced, as might have been expected. One second exposure in contact printing to unobstructed bright daylight is far too much exposure, and is sure to produce the effect described, even if slow plates are used.

S. A. R. writes: "Is it customary when a studio is built on the top of a house to fit it with a lightning conductor, and, if so, should it be of iron or copper, and what thickness?"—It is not at all usual to have lightning conductors to studios; though, if the studio be very elevated and much exposed, a conductor might be a protection. It is best of copper. A stout cable, such as those employed as leads in electric lighting, will answer.

A. SIMMONDS inquires how *eau de javelle* solution, which is sometimes recommended as a hypo eliminator, is made, as he cannot obtain it in his town.—Take dry chloride of lime, two ounces; carbonate of potash, four ounces; water, forty ounces. Mix the chloride of lime with thirty ounces of the water, and dissolve the potash in the remainder; then mix them and afterwards boil and filter. The solution is then ready for use.

E. H. WHITTAKER.—Five albo-carbon burners arranged in the manner described ought to answer for illuminating a sheet of ground glass as a backing to a negative that is to be enlarged, but six would answer better, especially for a 10×8 negative. Arrange them in two horizontal rows of three each, the outside ones being nearly opposite the corners of the plate. The firms mentioned prefer daylight for enlarging, when it can be got.

J. writes: "Wishing to make a quick emulsion for opal plates, I have found formulae in the ALMANAC for 1885, page 116. The exposure of this is long to my idea against commercial plates. Would you kindly give me an idea of any good formula, if published, for plates and paper?"—The emulsion is a very good one for the purpose. If greater rapidity be desired it may be obtained by longer boiling. As a rule, however, very rapid emulsions do not yield such satisfactory results on opal as slower ones.

A. REID says he is much troubled with the silver in his washing waters. The chloride will not subside. When the cask is full he adds some salt, but the water remains milky, even after a week, unless the cover is left off, then it turns brown with the light, but still keeps turbid. He asks how is this to be remedied?—The best plan is to pour in a few ounces of hydrochloric acid and then stir vigorously for a few minutes; after this treatment the chloride usually subsides in a few hours, leaving the supernatant liquor perfectly clear.

R. MARSON asks what is a Buckle's brush for spreading silver solutions, and where it can be procured.—A Buckle's brush is simply a tuft of cotton wool in a piece of glass tube. It is made as follows:—Take a piece of glass tube—a test tube with the bottom knocked out is the best—then double a piece of twine and pass it through the tube; take a piece of cotton wool and put it in the loop of the twine, and gently pull it into the tube by the other end of the string. The brush is finished when the loose filaments of cotton have been removed.

STEAM.—The method by which "the excellent photographs of machinery" you allude to are produced is this:—The ironwork is painted of a slate colour, and is then photographed in the ordinary manner. After the negative is taken the paint is cleaned off. Unless you can have this done in your case it will be impossible to obtain from the bright metal results that will compare favourably with those mentioned. Probably, if you explain the matter to your customers, they will adopt the same system as other firms who have all their engines photographed.

RECEIVED.—Ein Frager; A. Sewell; A. Pringle; L. M.; W. Guttenberg. These in our next.

A FRENCH politician of note is credited with a clever plan for ridding himself of unwelcome and importunate visitors. A photographic apparatus stands just in front of his study door. When a stranger enters his room his "groom," by means of a simple contrivance, takes his portrait offhand. If the master of the house has no wish to receive his visitor again, this portrait is at once placed in the collection of counterfeit presentments of persons not to be admitted on any pretext whatsoever. The "groom" in his leisure moments makes himself familiar with their features, and the politician is spared a vast amount of trouble and annoyance. So the story goes. It does not, however, fall to the lot of every public character to possess a "groom" who is not only handy with the camera, but has such a memory for faces.—*Daily Telegraph.*

EIKONOGON EXPERIENCE.—Messrs. Marion & Co. write: We think your readers will be interested in a letter just received from Messrs. Fradelle & Young respecting eikonogen developer, a copy of which we annex:—"We have tried and are much pleased with the eikonogen developer, but think that the instructions sent out with it are unnecessarily complicated. We think you may possibly be interested in a slight modification of it which we use in our practice, as follows:—A ten per cent. solution of eikonogen, i.e., one ounce eikonogen, four ounces sulphate of soda, made up to ten ounces with water. A developer can be made up from this stock as required in the proportion of one ounce of stock to ten ounces of water. So powerful is this developer that we find an accelerator rarely necessary, though it can be used, apparently to any extent, by adding as required from a ten per cent. solution of common washing soda, or the developer retarded by a ten per cent. solution of bromide. This arrangement will be found to be the essence of simplicity, and the results leave nothing to be desired.—Fradelle & Young, 246, Regent-street, W."

TWO NEGATIVES MAKE ONE POSITIVE.—No moment of a man's life, it is said, is more trying than that in which he "pops the question." Doubtless the assertion is true, though we have never tested it (for we are a bachelor), yet most assuredly there are hundreds of men who, at such a ticklish time, have been completely crumpled up and unable to screw their courage to the sticking-place. Faint hearts like these naturally resort to stratagem, and one of them has called photography to his aid. He purchased a camera and made himself master of the details of the art. Then he resorted to his charmer's home, and requested the honour of taking her portrait. He took it, and retired to develop the negative and print off. Again he came and implored another sitting. She granted his prayer. Day after day the damsel anxiously waited for her likeness. At length the amateur appeared. "Where is my photo?" she exclaimed. "You already have two negatives, what more do you want?" "Darling," he stammered, "you know what two negatives make, don't you? An affirmative is what I want." And, as her fair head fell on his manly breast, she whispered, "Dearest, you shall have it: that's positive."—*Modern Society.*

No. 1534. VOL. XXXVI.—SEPTEMBER 27, 1889.

BLISTERS ON ALBUMENISED PRINTS.

THERE are certain photographic annoyances which, after lying dormant for a period, burst their spell of inactivity and make their existence felt almost as an epidemic.

From the complaints of numerous correspondents, we are of opinion that those which are most in "eruption" at the present time are such as are associated with albumenised prints, and that the disease assumes the form of spots on such prints after they have been finished, and blisters on them previous to the stage of finality having been reached. It is to the latter—blisters on albumenised prints—that we at present direct attention.

Blisters usually make their appearance when the prints are transferred from the fixing bath to the washing water, in which the albumen tears itself up from the paper and forms a sac. Some of these sacs are small, not greatly transcending, in dimensions the size of a pin's head; others are larger, extending to upwards of an inch in diameter. The smaller ones usually dry down ultimately, leaving their presence unknown and unfelt in the finished print. Those of large dimensions, even when pricked by a needle, as some printers do, make their existence apparent when all the operations have terminated. We have had some large blisters carefully removed from the supporting paper, and upon examining them under a microscope have found that the albumen, when separating from the paper, has done so under such pressure from below as to have carried with it some filaments of the paper.

As regards the ultimate cause of blisters: it is, we think, most intimately associated with osmotic action, both the paper, on the one side, and the albumen, on the other, being in themselves septa. On the principles involved in endosmosis and exosmosis we do not consider it necessary here to enter, but will assume them to be understood; at any rate, their effects and the laws by which they are regulated.

We have, years ago, explained the application of these principles to the blistering of paper when removed from a dense liquid, such as the hyposulphite fixing bath, to a rarer liquid—the washing water; but a recapitulation may not now be unnecessary. A highly starched plain paper is, in itself, an osmotic agent, although when much resin is present it may cease to be so. The albumen on the surface, when coagulated by nitrate of silver, also possesses the same property in an eminent degree. Now, presuming the print to have passed safely through all the previous stages of preparation until it is immersed in the dense hyposulphite solution which permeates the whole texture of the interior of the paper, it is then placed in a dish of water at a lower density, when osmotic action is at once set

up through the albuminous, or paper septum, which separate the denser liquid within the paper from the rarer one without. The consequence is that the water passes through the septum into the interior of the paper more rapidly, and in greater bulk than the saline particles of the hyposulphite can find their way out, the final result being that the albumen is pushed up from the paper by a pressure from within.

At the time when we first gave this explanation, we suggested, if not a cure, at least an amelioration of the evil of blistering by immersing the prints in several solutions of continuously lessening density before immersing them in plain water, and this we know is now being practised, especially in America, the prints undergoing an intermediate transference to a plain solution of common salt after being lifted from the fixing solution to the water.

Other cures for blistering have been suggested. One which we and others have found most excellent was published in our ALMANAC for 1878 by that clever photographer, Mr. John Stuart, of Glasgow. After lying dormant, in a sense, for more than ten years, it is now being rediscovered by others. In justice to Mr. Stuart we give an extract from his article, from which it will be perceived that the *new* cure is not so very new after all.

"I am not ashamed to say that I had very much trouble with blistering, and I think that everything stated by different writers in the JOURNAL as a remedy for this disease has had a fair trial, but without success. When almost driven to despair, blisters will as suddenly disappear of themselves, and for months, perhaps, not one will be seen. I am happy to say they have now been conquered, and that in a very simple way. I am bound to say the treatment, if anything, improves the prints. Here it is:—After toning and washing in clean water for a short time they are simply immersed in common methylated spirits of wine (not that sold as 'finish') till such time as they have a semi-transparent appearance, which will be, in fact, about three to five minutes. Now lift them out, press as much of the spirit out as possible, and then wash in a few changes of water; after that they are ready for the fixing bath. After such treatment blisters will be things of the past. Now I would say to any one troubled with these photographic plague spots—'Try, and don't doubt till you have tried.'"

At this stage we leave the matter, and say with Mr. Stuart, "Try it."

A PHOTOGRAPHIC STANDARD OF LIGHT.

THE recent French Congress on photography has brought up once again the question of a photographic standard of light, but its recommendation of the acetate of amyl lamp cannot be said in any sense to have brought us a step nearer the solution of the difficult problem.

The question is one that affects equally, though in different directions, both the scientist and the every-day photographer, and to each it presents difficulties of no ordinary character. To the man who is scientist first and photographer afterwards, so far as it suits his purpose, the task of establishing such a standard no doubt appears perfectly easy, and only requires the co-operation of all engaged in photography to secure its general adoption. To him the selection of the Violle, pentane, or amyl standard light, and its careful comparison with some photometric standard outside photography, is all that is wanted; but the scientific photographer will want to know how the accepted standard is to be compared with daylight, and how if compared satisfactorily for one sensitive material, or one haloid salt of silver, the comparison will answer for other preparations. Above all, he will be anxious to know whether the nature of the standard light is sufficiently near in character to that of daylight, that is to say, whether the spectra of the standard and of sunlight are so similar that the readings of the standard actinometer may be taken as any guide to camera exposures, especially with orthochromatic plates.

Those who have interested themselves in photometry ever so slightly are aware of the immense difficulties of a mechanical nature that surround the maintenance of a uniform light for measuring purposes, even when the utmost precaution is observed. But only those who have devoted themselves to the study of actinometry as distinct from photometry can imagine the innumerable complications that arise both from the varieties in the composition of different lights and from the varying and disproportionate sensitiveness of different materials to the different coloured rays. An instance of this is afforded in the case of the Warnerke sensitometer, which, as is well known, is of little use for purposes of comparison owing to the wide difference between the spectra of the phosphorescent tablet and of the sun. Not only is the comparison between the tablet and daylight unreliable on account of the constantly varying composition of the latter, but the relation between plates of various kinds tested by the tablet itself is not accurately determined owing to the varying sensitiveness of the different haloids to the rays of different refrangibility. As the light emitted by the phosphorescent plate is practically devoid of all rays of lower refrangibility than the blue, it is clear that, as compared with daylight, which is often in winter almost free from blue or violet rays, the Warnerke sensitometer can be no real guide, and, as a matter of fact, it is not an unusual circumstance to find the comparative relations, as regards rapidity, of two plates to be reversed when tried by the tablet and daylight respectively.

The same discrepancy of course exists more or less with all artificial lights, but, perhaps, the greatest difficulty really exists in the utter want of uniformity in daylight itself. Thus, unless we establish an arbitrary standard supposed to represent sunlight, at its best it is impossible to fix a unit of measurement even for films of known composition. To fix such an arbitrary standard is, of course, no more difficult or unreasonable than in the case of lenses where a lens of the working aperture of $f/4$ has been chosen as the unit, or the mechanical unit of power is represented by a horse capable of lifting 33,000 pounds one foot in a minute. These two last units establish data upon which other calculations can be based, but in the case of light and sensitive films we have to reckon in addition with variations in the composition of both.

If a standard of light is to be established, it seems to us, in

the present state of our knowledge, that it must be an artificial one, solar light or daylight being entirely ignored and left, much as it is now, to the judgment of the operator. In that case the light selected should be one which as nearly as possible approaches to solar light in richness in the active rays. We have no personal acquaintance with the acetate of amyl lamp, so cannot speak as to its character, but we imagine that it is proportionately richer in the rays of low refrangibility than sunlight, and if so it can scarcely be taken as the best standard, even if in point of mechanical construction the lamps can be made to ensure a uniform light without needless trouble.

But magnesium, in its composition, is very similar to solar light, being rich in the violet and blue rays and containing a due proportion of those of lower refrangibility. It is cheap, it is easy of ignition, and it seems to us that, under the same conditions as those applied to the Violle and other standards, this metal, in the form of ribbon or powder, would provide a much more convenient standard.

Some years ago, when a Sub-Committee was appointed by the Photographic Society of Great Britain to study the subject, the result of whose labours was the selection of the Warnerke standard, we believe that, in the course of their labours, they experimented with magnesium as the light to be used, taking, if we remember rightly, a reflecting surface of given size in front of which the sensitive surface to be tested and the magnesium lamp were placed at fixed distances. The exposure was to be measured either by time or by weight of metal consumed, both being tried, but for some reason this light was rejected in favour of phosphorescence, with all its defects.

But it appears to us that a better plan, and one that presents all the advantages of the acetate of amyl or pentane lamp, would be to take a lantern of given dimensions provided with a perforated screen, with an aperture giving a constant area of illuminatory surface, in front of which, at a stated distance, the tests could be made just as in the case of the acetate of amyl or other lamp. The magnesium would be burnt at two or more points at fixed distances from a reflector of suitable character, and we can see no reason why, with equal precautionary measures, a light should not be so obtained possessing the same uniformity as that obtainable with the standard proposed by the French Congress. In simplicity of construction, convenience in use, and in general accessibility to all—not unimportant points to the photographer—the magnesium lamp would, we think, be far and away superior to the acetate of amyl, which at present exists only as a *rara avis* even among scientific men.

From the light we come to the method of graduation. On this point we think there can be not the slightest doubt that in order to establish a really useful international standard, all translucent graduated screens in any form whatever must be discarded. Such, even if they can be produced mechanically in truly graduated "tints," which is doubtful, establish an arbitrary scale, which is meaningless and useless to any one not possessing the particular screen. There can be no dispute as to the superiority of some system in which the time of exposure is graduated by mechanical means, or otherwise varied. This principle was first propounded, we think, by Mr. Alexander Cowan some years ago, that gentleman having constructed an actinometer, or rather sensitometer, based on the lines of a "drop shutter" having apertures of different lengths, but bearing a definite relation to one another. This, however, without some chronometric arrangement of a costly nature, gives no absolute measurement of the time of exposure and,

again, without some mechanical attachments to give long as well as brief exposures is restricted in its application.

The system based upon the revolving disc with a graduated aperture or apertures is, however, free from these faults, and, moreover, enables a maximum exposure which, if of some length, may be timed with greater accuracy than a short one, to be subdivided into extremely minute fractions of a second, and the time required to impress a given plate with a developable image, or one of a given degree of strength, as may be decided, can be stated in definite arithmetical terms.

The next question is that of development, which presents, perhaps, as great difficulties as any yet encountered. First of all, how is the standard developer to be composed so that it will treat with equal impartiality every kind of plate? Photographers well know that the best developer for one plate may be the very worst for another; how, then, are we to treat two plates of varying character in this respect with the same standard developer? Then, again, in actual practice we do not develop *by time*, but apply judgment as to when the best result has been obtained. Are we, then, to apply a standard developer for a definite time?—in which case the test will undoubtedly be unfair to some plates and favour others—or are we to “get out as much as possible,” regardless of time? In the latter case much uncertainty must arise from the varying judgment of the operator.

Lastly, what are we to develop for? Are we to accept the first faint sign of an image as the sign of the plate's impressibility and consequently its sensitiveness? or are we to aim at a certain degree of density? In both cases so much depends upon the character of the plate, that we question whether any practical result will ever be arrived at in making sensitometer trials a test for camera exposures.

These, and many other difficulties, present themselves in the matter of the establishment of a standard light or a standard system of actinometric measurement; and there are many points in which, by individual experiment and public discussion, much may be done to clear the way before any concerted action is taken in the matter by the Congress or any other body.

Here, then, is a subject which some of our more scientific readers may take up with advantage during the winter months.

NEGLECTED PROCESSES.—CERAMIC PHOTOGRAPHY.

Is it not a little surprising that ceramic photography has received so little attention at the hands of photographers generally? For, not only is it capable of yielding results which for beauty cannot be surpassed, but as regards stability, pictures burnt with ceramic ware may be well considered *par excellence* the most permanent of all photographs. At different times doubts have been raised as to the permanence of photographs by almost every process in vogue, but, so far as we are aware, no question has ever arisen with reference to the stability of a vitrified picture.

Ceramic photography is of comparatively early date, and at various times has formed the subject of several patents, all of which, with one or two exceptions, we believe have expired. One of the first to produce really good vitrified photographs on enamel, commercially, was M. Lafon de Carmarsac, and excellent they were. Indeed, up to the present time they have not been surpassed as untouched pictures, except perhaps in size. Later on Carmarsac had a number of imitators, and enamel

photographs were produced by several photographers in this country, who, for a time, made them a speciality. At present, however, we do not imagine that vitreous photography is practised by over half a score of photographers in the whole of England, and by them only to a very limited extent.

The production of “burnt in” pictures is really a very simple matter. There are different and totally distinct methods by which they may be made, each of which is capable of producing excellent results. And what is more, none of them require any expensive plant to work them. All the apparatus necessary, beyond that to be found in every photographic establishment, is a muffle furnace for the “firing in.” Small gas muffles, though large enough for working enamels up to five or six inches, may be had for 3*l.* or 4*l.*, and they require no fixing.

One of the simplest, and for small sizes, perhaps, the most satisfactory method is what is known as the substitution process. This, briefly, consists of first making a transparent positive from a negative by the wet collodion process on a glass plate. After the picture is completed, as a transparency, the reduced silver forming the image is toned, or rather replaced entirely by another metal, which, when vitrified, will yield a picture of the colour desired. If the silver image were burnt in at this stage, as might be done, it would produce a yellow picture similar in colour to the silver flashed glass supplied for dark-room windows. Hence, to obtain a black or purple colour some other metal must be substituted for the silver. Platinum, palladium, iridium, &c., may be employed according to the particular tint desired. The first-named is the metal most generally preferred. The transparency is simply placed in the “toning bath” of a chloride of the metal until the whole of the silver has been replaced by the other metal. The chloride of silver formed in the operation is then dissolved out. This, it is manifest, if left in, would cause an unpleasant yellowness in the finished picture. After toning and fixing, the collodion film is transferred from the glass plate to the enamel tablet, and, after drying, placed in the muffle. A few minutes of moderate heat, according to the fusibility of the enamel, is all that is necessary to vitrify the image, which is afterwards glazed with a soft and easily fusible glaze.

Another method, and one practised by some, is the dusting-on process, using, of course, vitrifiable pigments, such as those employed in porcelain painting. This process possesses some advantages over the substitution one, inasmuch as with it any colour or tint of picture may be obtained at will by selecting a suitable pigment, whereas, by the substitution method, the colours available are more restricted. The weakest point in connexion with the powder process is the difficulty in obtaining enough force in the shadows, that is, in getting the bichromated film to retain a sufficient body of pigment to yield the desired vigour. The pictures can, however, be strengthened by retouching and then refiring. This treatment most workers by the powder process have found to be a necessity.

The “carbon process” has also been made available in ceramic photography, and it is, perhaps, better adapted for the production of work of large size, on a commercial scale, than either of those just referred to. In this case the tissue is made with a vitrifiable pigment, instead of the ordinary colours. At first sight it might appear that this would be a very simple method to work, as it would only be necessary to develop the picture on the enamel or porcelain plaque, and then fire it into the ware. Unfortunately, however, there is—as there is in many other apparently simple processes—a little difficulty in the way. This difficulty is that when the heat is applied the gelatine

contracts, cracks, and then frizzles up and leaves the plate, of course taking the pigment with it. There are methods by which this difficulty may be overcome, but they are either treated as a trade secret or made the subject of a patent.

There are one or two foreign firms, however, who produce vitreous photographs for the trade here, and at moderate prices, but the business in them is very limited. This may be fully accounted for by the fact that no professional photographers, so far as we are aware, make them a speciality, or put them forward as they do almost every other style of picture. Under these circumstances it is not so very surprising that ceramic photography has, at the present time, to be classed as a neglected process.

The applications of ceramic photography, apart from portraiture, to which direction it has been chiefly confined, are too numerous to be detailed here; suffice it to say that it is admirably adapted for pottery and art work generally.

COST OF SILVER NITRATE.—The alloy in standard silver being seven and a half instead of ten per cent., as suggested in our article on this subject, the value of the metal in ounce comes out almost exactly $20\frac{1}{4}$ pence, or very closely five-eighths of the market price of standard silver.

REFERRING to the footnote in our issue of the 23rd ultimo, wherein we printed two of the Convention papers contrary, as it appears, to the decision of the Council, we have to express regret that the mistake occurred. The Council, *as a body*, was not responsible for the mistake, as there was, in fact, no meeting of the Council at the time. We add this to our previous explanation at the request of the ex-President, who fears that our previous acknowledgment was not sufficiently explicit thoroughly to exonerate the Council.

INTENSIFICATION by mercury is so simple and so sure, that it is scarcely probable it will fall into disuse; but simple as it is, certain precautions have to be taken to get the best results. *En passant*, we may say that a thorough investigation of the theory of the process has never yet been made, nearly all the text-books containing erroneous statements with regard to it. Such an investigation ought to lead to valuable results, for the conditions under which mercurially-intensified negatives fade are quite unknown, some produced years ago by a certain process being in good condition, while others again, but a few months old—intensified apparently under identical circumstances—being injured beyond repair.

SOME operators ascribe great virtue to a plain solution of bichloride in water, while others consider that chloride of ammonium should be employed as an aid to solution. We need not say that much stronger solutions can be produced in the latter than in the former mode, one part in nineteen being the maximum of solubility in cold water, alcoholic and ethereal solutions containing one in seven and six respectively are not of practical value although stronger. Other operators, again, prefer the iodine compounds of mercury. Mr. Edwards's method of precipitating bichloride solution by iodide of potassium, and adding "hypo" till almost all is redissolved, is perhaps the most elegant of all methods; it is so easy to intensify locally or wholly; and the result it is not possible to distinguish from a non-intensified plate. When plain solution of mercury, followed by ammonia, is employed—and this is the oldest and commonest of all—it is very necessary to wash well between each stage, or irremediable stains are produced. There is one point requires elucidating in the action of the ammonia: we refer to the difference in colour produced (which every one must notice) according to the degree of dilution of the ammonia solution.

It is quite possible that variations in the nature of the intensified image may be produced by the state of the ammonia itself. For example, the ammonia may contain a considerable amount of car-

bonate, the action of which is not known, and it occurs to us to suggest that experiments in this direction might be made with advantage. We lately pointed out the liability of ammonia to become contaminated by absorption of carbonic acid from the air, and it has been pointed out by a writer in the *Chemical News* that the presence of this salt exercises a remarkable action on other mercuric precipitates. For example, ammonia solution, as is well known, throws down from a bichloride a white precipitate, but when it contains a certain amount of carbonate the precipitate is redissolved entirely. May not some similar variation of action be produced when the ammonia solution is poured on the mercurialised plate?

BEFORE leaving the subject of mercurial intensification, we would call attention to the fact that most negatives so intensified can be reduced in intensity if required by solution of hyposulphite of soda. One method of treatment of an over-exposed picture has been founded on this plan: the negative is to be reduced by ferricyanide, intensified with mercury, and finally brought to the exact printing strength by hypo solution.

ONE of the most remarkable feats of photography on record is the photographing the terrible explosion at Antwerp, or if not the explosion, the immense cloud of smoke produced at the moment. The current number of *La Nature* gives an illustration copied from a photograph of the huge cloud that shot up in the air, roughly in shape like an inverted Florence flask, when the explosion occurred. It has been estimated as being seventeen or eighteen hundred feet across, and, according to the journal quoted, the cloud remained motionless for about a quarter of an hour, preserving the form recorded by the photograph. It seems very remarkable that just at the instant some one should have been ready with camera and plate and quick-witted enough, notwithstanding the shock, to secure the view in time. The author of the negative is given as M. L. Van-Neck.

PRACTICAL heating by electricity has too often been looked upon as the dream of a visionary, but we read that it is now an accomplished fact, and that apparatus is being made and sold by a public company for utilising electricity for railroad-heating, house-warming, cooking, &c., so that now it may be possible for those photographers in possession of an electric installation to utilise a portion of the surplus power for heating the studio and other portions of the premises. The apparatus consists of a series of coils enclosed in cast-iron cases forming the radiating surface, and provided with points for increasing the available surface. There seems a real probability of this being a practical invention, and the inventor, Dr. Leigh Burton, has received a prize from the Franklin Institute for his invention.

LANTERN SLIDES ON GELATINE PLATES.

Now that the lantern season is rapidly approaching, we shall no doubt once more have the battle of gelatine *versus* collodion fought over again. It is not my intention to enter into the argument here, further than to say, that where collodion plates possess their undoubted advantages, gelatine is indubitably the more convenient process to employ for many, both on account of its great rapidity, as well as the fact that it is in many cases the only process with which the photographer is familiar.

Further than this, I will only say that I am not one of those who condemn gelatine plates for transparency work. On the contrary, if the right precaution be observed, I believe transparencies of the very finest quality may be obtained with little more trouble than negatives. Naturally, those who attempt to apply rapid landscape plates to a purpose for which they are wholly unfitted must expect to meet failure, just as would have been the case in the old collodion days if a man had tried to make his transparencies with a neutral bath, freshly iodised collodion, and the most energetic developer he could obtain.

I say I am of opinion that with proper precautions gelatine plates may be made to run collodion very close for quality, and still have very much the advantage in rapidity, though far inferior in that

respect to the sensitive plates of commerce. In the belief that there are still some amateurs left who, like myself, are not only not afraid, but actually prefer to do some of their own work in emulsion making, I propose to describe in detail my method of making lantern plates, premising that all I claim in the process is the systematically adapting to amateur requirements the advice and instructions given by other writers.

In the early days of gelatine plates it was the general complaint of "old hands" that the new plates would not give the same "quality" as wet collodion. With increased familiarity with the process, and improved methods both of manufacture and of development, this gradually wore off, though even at the present day it is not unusual to hear similar, though milder expressions of regret. Whether or not there be really any truth in this suspicion of inferiority of gelatine for negative work, undoubtedly there has been ample ground to complain of the quality of the transparencies turned out by its aid. I have frequently seen, though not to the same extent recently, at mixed "lantern shows" a series of slides upon gelatine plates thrown on the screen in immediate succession to a number of collodion ones, with such an effect as must have made the producer feel very small.

Many of the commercial negative plates now on the market are so nearly perfect in their mechanical and chemical qualities, that it is difficult to see in what respect they can be improved. For negative purposes the character of the image for gradation, clearness, and colour seems unsurpassable; and yet, if one of these be developed as a transparency, and compared with a similar one on collodion, there will be a strong difference in favour of the latter. The special "lantern plates" prepared commercially, so far as my experience with them goes, differ from ordinary plates only in being slower, and perhaps, though not necessarily, in consequence capable of giving a clearer image with less trouble. In at least one instance I have a strong suspicion that a wide departure is made from the ordinary "salting" of the emulsion; but, as a rule, there appears to be little variation from the every-day routine.

What is required is a plate that will give perfectly clean lights, not merely free from fog and developing stain, for that any ordinarily good plate will do, but free from opalescence or granularity of the film of gelatine itself. Next, we require fineness of deposit, that is to say, the particles of silver must be so minutely divided as to be individually unrecognisable even under powerful magnification. The image should form, indeed, a homogeneous "stain" rather than a delicate stipple or grain, and even in the deepest shadows be perfectly transparent. The next quality is the capability of giving density and gradation—the two must go together, and the last is tone or colour. Each of these I will briefly touch on separately.

First, with regard to clearness of image. In the sense referred to here as distinct from fog, it may be said to depend entirely upon the gelatine and the method of treating it at every stage. Many samples of gelatine are, as met with in commerce, utterly unsuited to our present purpose, though perhaps well adapted for negative purposes, owing to a very slight opalescent appearance not noticeable in the shadows of a negative, but seriously detracting from the brilliancy of the high lights of a lantern slide. This defect is usually due to the presence of lime in the gelatine acquired during the process of manufacture, but it is not always so. Minute particles of other foreign matter emulsified, so to say, in the gelatine will also produce a partial opacity, as for instance in the well-known Nelson's "opaque" gelatines, the names of which, however, scarcely do them justice from a photographic point of view.

Lime when present in the insoluble form is extremely difficult, if not impossible, of separation, as in converting it to a soluble condition the chances are the gelatine will be itself decomposed. When present in the soluble form, as it invariably is, partly as a constituent of gelatine itself (phosphate of lime), the lime is always liable to be precipitated by any solution capable of forming an insoluble salt and becomes practically unremoveable. The substances capable of so forming insoluble salts include caustic alkalies, carbonate, hard water, solutions containing oxalates, citrates, and many others, so that it will be seen, while it is impossible to keep entirely clear of lime in the gelatine itself, it behoves us to use every endeavour, not only not to aggravate the injury arising from that already there, but to avoid introducing more.

The first step, then, is to select a gelatine that is free from all visible traces of lime, and which shows but little signs of it when allowed to swell in a solution of caustic soda in distilled water. A sufficiently pure sample having been obtained, we must avoid introducing more lime by using only distilled water in making the emulsion, and avoiding, as far as possible, the use of tap water at any stage. If a gelatine film or emulsion in an alkaline state be washed with water containing lime, carbonate or hydrate of calcium is sure to be deposited, and in the case of an emulsion ripened with ammonia and washed in ordinary tap water, the opalescence so caused is sometimes remarkable. With a very "hard" water even the washing a film after development is sufficient to produce a visible veil.

Similarly all solutions containing citrates, oxalates, or alum (especially if the film be alkaline), should be used with the greatest caution. The citric acid and alum "clearing solution" should be replaced where necessary by that containing hydrochloric acid. The ferrous oxalate developer should be used only in conjunction with distilled water, the negatives after development being soaked for some time in distilled water rendered slightly acid with acetic acid before being passed into ordinary water, which even then should be boiled or rain. Alum should never be applied to a plate that has not been well washed after leaving the developer.

I have said nothing about the presence of foreign matter other than lime in the gelatine, because such, if present, will most probably take the form of dust or other matter, removeable by means of filtration. If this be not the case, there is little hope of doing any good with the sample of gelatine, since the process of clarification with white of egg is so troublesome, and withal so uncertain, that it is not worth resorting to. The best way of filtering is to have made a conical bag, precisely similar to the cook's "jelly bag," of two or three thicknesses of close flannel or felt, or, better, fine chamois leather; sew this on to a ring or hoop of cane, by which the bag may be suspended to the roasting jack in front of a hot fire.

To prepare the gelatine, let it soak for a few minutes in perfectly clean rain water previously boiled, filtered, and allowed to cool. When quite soft take the sheets or "leaves," one or two at a time, and carefully and thoroughly rub them upon one another with considerable friction to remove any adherent dirt; rinse well and allow to soak in distilled water until sufficiently swelled. Liquefy by heat and raise the temperature until it reaches 180° Fahr. Dip the filter bag, previously quite clean, into very hot water; wring it out quickly and hang it before the fire, pouring the hot gelatine into it, with a suitable receptacle to catch it as it passes through. No matter how thick, it will quickly pass through the filter if kept hot and fluid, for which purpose it should hang pretty close to the fire, and it must be kept revolving in order to prevent the gelatine drying on the surface of the filter, as would be the case if allowed to remain stationary. If needful the filtration may be repeated a number of times.

A stock of gelatine so clarified may be poured out on to slabs of glass rubbed with oxgall and allowed to dry for future use; or the quantity required may be operated on each occasion. The advantage of clarifying the gelatine before adding it to the other ingredients of the emulsion is that the operation can be performed so much more thoroughly, and it is perfectly easy whatever process of emulsification may be followed, as it may be cleared in solution of four or five times the concentration of the emulsion, and subsequently thinned down.

With regard to fineness of division, this is a quality now almost ignored in ordinary "rapid" plates since the sensitiveness is supposed to require a certain degree of granularity. It is true that rapidity and coarseness generally run hand in hand, but it is by no means necessary; however, for our purpose, it is satisfactory to know that fineness of division is quite easy to secure, though in conjunction with rapidity it is not so.

Coarseness of deposit—by which I mean a degree of granularity plainly visible with a magnifier—began to be the fashion when the practice of boiling in the presence of a small proportion of gelatine, or digestion with ammonia, came into fashion as rapid methods of securing high sensitiveness. In Bennett's process extreme fineness of division accompanied the utmost rapidity, and even in the "boiling process" it is possible to get a fine deposit accompanied by sensitiveness, but it requires care. Naturally the precipitation of the silver bromide in a solution of gelatine containing only two or three grains to the ounce

will be quicker, as well as coarser, than when twenty grains of gelatine are present. But as for our purpose we do not require to boil, and are not therefore likely to destroy the setting power of the gelatine in that way, we may mix up the full quantity of gelatine at once, and thus secure to the fullest its assistance in giving us a finely-divided bromide. No other conditions are needful beyond a comparatively viscous emulsion and digestion at a moderate temperature, not too prolonged, to produce the finest grained emulsion it is possible to obtain. Such an emulsion, if properly made in other respects, offers advantages quite distinct from the merely physical character of the image. It assists greatly in securing both density and gradation as well as colour-giving properties, which, by the way, are more dependent upon formulæ and development than anything else, and I shall therefore touch upon them under those heads.

C. BECKETT LLOYD.

PRACTICE AND THEORY.*

THE negative having been taken, it has to be printed. As to the process that will give the most artistic results, opinions differ, and in all probability will continue to do so till the end of time. There is, undoubtedly, in the present day a general preference for matt-surfaced prints, with which novelty and the vagaries of fashion have probably something to do; at any rate, the matt surface and cold colours are decidedly in favour. Before platinotype came into popular notice, the greater part of plain paper prints had a slaty sunken appearance, with flatness and want of detail in the shadows. These contrasted with the brilliant albumen prints were decidedly inferior. Platinotype, however, showed to the general public that strong brilliant prints could be made without a shiny surface; this gave an impetus to the production of other prints than albumen ones. Unfortunately, negatives of all kinds and qualities are required to be printed from; some very valuable ones, perhaps unable to be again obtained, but bad in quality; have to be made the best of. If we were limited to matt-surface paper for printing them upon, the results would be a sorry hash; but here the albumen process comes in, and no one experienced in the matter will deny that for all and every kind of negative there is no process extant that can approach silver printing for efficiency. Its adaptability is marvellous; quite presentable prints can be made from the poorest apology for a negative; in fact, any negative that will print at all can be made the best of in silver printing. Take the average of negatives. How many are bright and faultless compared with those of varying degrees of mediocrity? The answer must be, very few indeed; and as all other processes require a special quality of negative, silver printing is tolerably sure of a long life in spite of all detractors. In silver printing we can see what we are doing—mask, dodge, shade, stop out, tint, and a score of other things that will tend to improve the work that cannot be so conveniently done in any other process.

There have from time to time been many papers with a matt surface put into the market that would give bright shadows and good colour. About twenty-seven years ago a Mr. H. Smith introduced a paper of this kind that he called Valetta Paper, and was worked exactly like ordinary albumenised paper, and gave very good results. I believe starch, lac, and gelatine entered into its composition. I used a good deal of it about that time for book illustrations, the prints keeping very much as ordinary silver prints would do—some have faded and some not, which fault I think may be attributed to imperfect manipulation, probably insufficient fixing. Fixing seems always to be the weak point when large numbers of silver prints have to be made. The chance is some will be fixed better than others; those last fixed coming off worst. Mr. H. Cooper, of Torquay, also prepared some, giving excellently bright prints, with a matt surface; he called his Resinised Paper. The formula was, I believe, published in one of the photographic periodicals, but I cannot call to mind exactly how it was prepared; any way, the results were charming. It should not be a difficult thing to produce paper that will give all the brightness and detail of albumenised prints without the gloss of albumen, and be sensitised with silver nitrate in the same manner. I do not think exception could be taken to such prints on the score of being inartistic any more than to the illustrations in an ordinary well-printed book on good paper. Such paper would, I imagine, be more permanent than albumen paper, which, to say the best for it, is a somewhat treacherous material. It often happens that paper albumenised in the spring and early summer is inferior in quality to that prepared later on in the summer and winter. I have been given to understand the reason of this falling off in quality is owing to the albumen used being in a great measure from eggs that have been artificially preserved.

* Concluded from page 619.

The albumen, although free from offensive odour, is poor and watery in comparison with that from fresh eggs, and the paper suffers accordingly. From my own experience I should think there is every probability that the explanation is correct. On such paper the printing results are flat and poor in colour, with a considerable amount of mottling and streakiness that no treatment will overcome. The sizing of the paper is sometimes irregular, the starch and resin not being so well incorporated with the pulp as they ought to be. The paper also gets albumenised before the size in it has had time to properly harden; the consequence is blisters, for which there is no remedy but time.

Mr. E. W. Foxlee and other experienced men have found that a badly blistering sample of albumenised paper may be quite cured of the defect if it is stored away for a considerable length of time without any other treatment. It is true certain conditions of temperature and strength of baths may somewhat alleviate the trouble, but as it frequently happens the paper is mixed in the same ream, some that will blister and some that will not, the deductions to be drawn from any experiments are unsatisfactory, as there are no means of distinguishing between the different samples beforehand. Mr. W. D. Richmond, following on the lines laid down nearly a dozen years ago by Mr. J. Stuart in the ALMANAC, found that by putting the prints *direct* from the printing frames into methylated spirit no blisters would form, although they went through all the usual processes afterwards without any special precautions; but this treatment did not prevent blisters if the prints were wetted with water first. This is an easy remedy and worthy a further trial, having the advantage of not diluting the spirit, as must be the case if the prints have been previously washed or toned.

If any large quantity of paper is consumed it is most economical to sensitise it at home on as strong a silver bath as the paper will bear; even with lightly-salted papers a sixty-grain bath will not be found too strong for the best results. A strong bath facilitates the toning, and adds richness to the colour of the prints. The best strength for the majority of the paper now in the market is between sixty and seventy grains of silver nitrate to the ounce of water. A guide to the best strength for the special sample of paper in use is the rapidity with which it bronzes on exposure to the light. With a negative of an average density, the margin of the paper projecting beyond the negative should be bronzed by the time the print under the negative is about three parts done; the deepest shadows in it should show a little trace of bronze. If no bronzing takes place, it may be considered that the bath is too weak, and the prints will be deficient in vigour; if too strong, the lights will be somewhat blocked, and the colour not so good, and the paper, also, will not keep so well, soon getting yellow. At the same time, bronzing does not altogether depend on the strength of the nitrate bath, the length of time of exposure and strength of the light having much to do with it; in a very weak light the uncovered margin of a print may be bronzed before the print itself is anything like sufficiently printed.

With regard to the keeping qualities of sensitised paper, it varies greatly according to the paper and the amount of free silver left on it. Many different methods of treatment have been suggested, but with many the toning is not sufficiently taken into account. It is very easy to make a paper keep well, if that was all; but to do so to tone well is another matter—the less silver left in the paper the longer it will keep, and the more, the better it will tone. Different makes of paper vary in keeping qualities, though prepared in the same manner, but with all, air and moisture are their greatest enemies, so to preserve them adopt similar means to those recommended by the Platinotype Company for keeping their paper. In all preservative solutions compounded with citric acid, to be applied to the surface after the usual sensitising, there must be a considerable amount of free silver, for unless there is, bright prints are impossible, and we get mealy, poor results. The manner in which the paper is laid on the silver bath to sensitise varies with different printers. However, there are only two methods that can be rapidly managed without producing faults. Let it be borne in mind the longer a bath has been worked the more albumen will it contain, and the bubbles formed will be of a more persistent character. On a fresh bath bubbles will form, but a very trifling disturbance will break them; but after a time they may be moved about on the surface, and break with considerable reluctance if they happen to remain unnoticed under the paper until it begins to flatten. The persistence with which they adhere is very annoying; merely lifting up the sheet and letting it down again, or a touch with a glass rod, will not be sufficient to get rid of them; they only disappear on being wiped with a scrap of paper, or something equally efficacious. The method of laying down the paper on the bath with the least chance of defects is either to roll up the paper tightly, face outwards, on a roller, for a short time before sensitising, so that when a sheet is held up by the two upper corners the lower edge will be curled. The curled edge is

carefully brought into contact with the silver bath, and the sheet slowly and steadily let down on to it, where it remains for the requisite time. The end first let down is then picked up, and the sheet drawn slowly over a glass rod fixed at the end of the tray, in order to remove as much surface moisture as possible. It is then either hung diagonally over a half-round rod, or suspended to a suitable frame by American clips till dry. The alternative method of laying down is not to previously roll the paper, but to take the sheet by the two *opposite corners*, bend the paper face outwards, lay down the lowest *corner* on the bath first, and gently let the sheet touch the bath diagonally, not relinquishing hold of the top corner till the sheet is quite down.

The advantage of either of these methods over bending the sheet and laying down the *centre* first, so often recommended, is that bubbles invariably form at that point where the paper first comes in contact with the solution, and it is *very* much more convenient to raise the edge or corner to get rid of them than lifting the whole sheet when the bubbles are in the middle. With regard to the time of floating. Three or four minutes are generally sufficient if the paper is not too dry, and having to ensure it being in a proper hygroscopic condition, it is best laid some hours in a damp place, until it becomes flimsy; there is not only less tendency to make bubbles, but the sensitising is more even under these conditions.

A very dry paper will frequently curl up at the edges, lengthways of the sheet, almost directly it is moistened, into a comparatively tight curl, so that the silver bath is carried on to the back of the sheet to its serious detriment. A slight tendency this way may be overcome by simply breathing on the back as it lies on the solution; but excessive dryness causes a most unmanageable curl that defies any amount of breathing. The paper must be forcibly held down on the bath until the moisture penetrates the paper, when it becomes tractable. To preserve the paper after thoroughly drying lay two sheets face to face, then a sheet of paper impregnated with carbonate of soda, then two more sheets of albumenised, and so on; put the whole between two boards with a weight on the top; in this manner without an air-tight case paper will retain its good qualities for a long time. A piece of the soda paper laid on the back of the albumenised in the *printing frame* is a good precaution; the only objection is, after using it some time in damp weather, it is apt to give rise to spottiness on the prints. The remedy is obvious.

As to printing, a good *diffused* light is almost always best, and only in cases of very dense negatives should the printing operations be carried on in direct sunshine. Direct sunshine gives rise to a good many defects—scratches and imperfections of the glass show badly on the prints, the colour is generally inferior, and delicate half-tones are much impaired—the only thing to be said for it is that it is a more expeditious way of turning out a quantity of work. As to the depth of the printing, no rule can be laid down. Given a good negative, and everything in proper working order, the printing should be finished when the deepest shadows are slightly bronzed, but even this depends on the density of the negative; there should also be a slight tint on the lightest portion under any circumstances; the print must be somewhat darker than it is intended to be in the finished work, to allow for reduction in toning and fixing. The weaker and thinner the negative, the weaker the light should be to print in; the denser, the stronger light. Prints from very thin negatives can be improved by laying a piece of pale yellow glass over the printing frame during the operation.

After printing comes the trimming process, either closely so that they require no further attention in this way before mounting, or roughly trimming the waste edges in order to economise the gold in toning the final trimming taking place after they are washed and dried, which I think rather the preferable plan, as the edges are apt to get softened during the soaking they get, and the finished prints do not look so nice and smart as when the trimming is deferred until the prints are dry.

If vignettes are wanted (that eminently inartistic style according to Emerson), the more gradual the shading off the better the effect will be. *Abrupt* vignetting, showing a definite outline, is for heads and busts most objectionable; the true vignette effect is positively murdered, leaving nothing but an oval or pear-shaped patch that will spoil the most beautiful picture ever taken. There are a great variety of methods in vogue for vignetting, and very good results can be had with any of them providing they are used with discretion. A popular plan, as easy and good as any, is to cover the print and negative with a perforated cover at a little distance from the frame, the aperture being somewhat smaller than the required vignette, the distance regulating the size of the picture and print in a quiet diffused light. A strong light may be used if the aperture is covered with tracing paper. It is of very little importance which plan is adopted; the idea

is to effect a gradual softening off of the image to nothing, and either plan will meet this requirement, but like other delicate operations it must be used with brains.

Printing on matt-surface or salted paper should be rather deeper than on albumenised, and the toning carefully watched, as the gold acts much more quickly on these papers. When ready-sensitised paper is used, or any paper preserved on an acid solution after the bulk of the silver is removed by the *first* washing, about an ounce of carbonate of soda to the gallon of water should be in the second, the soda being removed by subsequent washing before the toning takes place.

As to the *best* toning bath, really there is no best—almost any, used with discrimination, will give good colours. The favourite is perhaps the old-fashioned acetate or borax bath, as being easy to use and satisfactory in all respects when warm colours are required, and the lime bath for black colours. If a toning bath is required to be kept in stock the acetate is by far the best; it is always ready for use, and will last unimpaired for a very long time. The lime bath will not keep, and requires making an hour or so before use; it gives excellent colours, and for certain work it is difficult to improve upon; it is economical of gold, and is undoubtedly a good all-round bath. After toning put the prints into salt and water for a short time before fixing. Two hyposulphite baths are better than one; add a little liquor ammonia to each; let the strength of the first be one to six, and the print kept moving about in it for a quarter of an hour. Place them in the second of a greater strength—say, one to four—for a few minutes, then thoroughly well wash, and the prints are finished. The temperature of all solutions should be kept nearly as possible at 70°.

Respecting the nitrate baths, they should be kept neutral by the occasional addition of carbonate of magnesia. In all home-sensitised paper the presence of a *considerable* quantity of free nitrate of silver is absolutely essential to brilliant results. If very weak sensitising solutions are used, or the paper washed, it is necessary to make up for the deficiency of silver by adding some other nitrate or fuming with ammonia; but at best they are inferior to the stronger baths, both in brightness and uniformity of the resulting print.

EDWARD DUNMORE.

PHOTOGRAPHING OF PREPARED CANVAS AND SIMILAR SURFACES.

To the amateur or novice there will seem to be few substances on which the photographic image can be directly printed which would present more difficulty than canvas or panels prepared for artists painting upon; but although this is by no means a new idea or thing, yet as of late years so many people have devoted themselves to the camera that the subject must be new to many of them, and even many of those who have devoted their lives to photography know little or nothing of this out-of-the-way branch of their own work, and to all such it must prove interesting. To artists, also, it may be said that there is little use for them standing aloof on the pedestal of their own dignity, as we know, and very many of themselves also do, how much and greatly indebted they are to photography for the invaluable aid it has been able to render them. Not only is this the case, but it is perfectly patent to all who choose to look that it has quite revolutionised the landscape art, not only of this country, but of Europe, with perhaps the single exception of Holland and the Low Countries.

There the artists had acquired a habit of looking at nature so truly, and representing her withal so accurately, that they hardly needed that training which makes for truth, which photography has compelled all other schools to follow or adopt. But it is not alone in the mere drawing of landscapes that this class of fellow-workers are indebted; in other and what are considered by many to be the more important divisions of figure and portrait representation, they are not only aided in many instances with the drawing and light and shade, but also to the photographer are they often obliged for the very printed design on which to work, even though originally drawn by themselves.

To such an extent has this been carried by many, that it is within the writer's knowledge that several of the most famous names in art circles are content with either copying early but carefully drawn designs by the use of our art, but go much further than that and get the same reproduced on the canvas or the panel prepared for painting, just as the photographer does with his own work on the same materials. Nor should we find fault with this adoption of the mere labour-saving power which is here given, for if the superior artist chooses to do the mere copyist's work, he is only taking up time which he might use to far higher and nobler purpose; or if, as in many cases, he entrusts this simple copying work to a younger or inferior

hand, or to some of the cleverer of the young students, who are always proud to get such work to do, but which requires the continued and constant supervision of the artist himself to prevent deviation from the truth of line or change of expression in effect all unconsciously by the student copyist, and this requires much correction from the artist.

The photographer by his strictly mechanical copyism saves all this worry and bother by rendering it absolutely, whether right or wrong, in the first instance; and not only in this direction but in many others can this help be made available, and is, in the case where an elaborate design of figures or animals, or both in combination, has been made by the artist, and there is no probability of a popular reproduction by any of the various processes, he retaining the copyright of his work by this method gets the entire design in its light and shade, and to any size made for him, in a tithe of the time and cost and with ten times the certainty of even a replica by his own hand.

This is by no means a mere speculative statement, but one that is made with the fullest knowledge and with a long experience in doing such a class of work for men who have publicly contemned photographers and their art, but who are not above accepting the hundreds of pounds which have been got for their pictures, without mentioning the fact that they were painted on photographic copies of their own work truly, but still to the extent stated aided in the mechanical reproduction by photography.

The methods for producing this class of work now in common use are more or less objectionable, and they only need to be mentioned to show their ineptitude for the purpose. Any substance which has a body, such as a collodion transfer or a carbon print, or any other in which gelatine is superimposed or attached to prepared canvas, is not only bad, but is worse than useless, as it certainly tends by its unequal rates of contraction and expansion, and by being so amenable to the action of damp, to rend and crack the oil paint, as certainly as does the covering of the finished work with varnish before it is quite dry, and this is too often done.

It may be taken as an axiom in producing photographic portraits painted afterwards in oil colours, that there should be nothing which will prevent the perfect adhesion and union of the colours of the artist's palette and that of the prepared ground, and if I am not much misinformed this is by far too much the common practice.

What, then, is wanted is to treat the prepared canvas in such a manner that it will accept the printed silver image in such a way, and be as permanent, as that which was shown to be possible with all papers or plain cloth surfaces on page 524 of this JOURNAL, and that the picture shall be as much like an inkstain as possible; but before describing the mode of procedure guilt must be pleaded for urging the use both of the ornolu and of plain salted gelatine, though in minute quantities, for this purpose, and it was not until actual proof of not only the inutility but the positively deleterious effects came under observation, that this newer and better way had to be invented. It occurred in this way. One of the oldest and most respected persons in the business called my attention to a portrait which had been finished over one of these enlargements printed as indicated, and on a cursory examination nothing was apparently the matter, but on a closer survey it was found to be in a perfect network of fine cracks, and this became more painfully visible on looking through the canvas in a bright light. I had, from having recommended the way in which it was done, a kind of fatherly interest in the matter, and naturally felt much annoyed, and would not for a time believe that it was due to the method of preparation; but a deliberate destructive examination of the picture, which was not allowed to be sent home, proved that it was the interposition of the gelatine which had produced the ruin of a valuable picture, and thus paved the way for a better method.

In beginning, it is well to be careful in the choice of the canvas, as some of the examples occasionally prove somewhat refractory under the treatment. There can be no control over its preparation exercised by the photographer, the material being prepared without reference to his uses, so that all he can do is to select the best for his purpose, and this can only be arrived at by experiment. So far as description may go, that may be tried, but it would be obviously unfair to select and name a special maker or makers while there might be others, perhaps untried, which were quite as good. Broadly speaking, that kind called half-prepared is not quite so good for this purpose, even when made by the same makers as the fully prepared, although some of the best artists prefer it from the tooth it has, enabling the full freedom of a well-laden brush in the working. The principal reason why it is not so good is that the very thin layer of priming colour allows the texture and the more prominent fibres of the cloth to project in a slightly rough manner, and thus while in preparation for being printed upon the very thin layer on the topmost points is apt to be washed bare, and thus bring into contact with the cloth

and its gelatinous coating the sensitising solutions, which is best avoided.

The same remarks apply to most of the French rough canvases, and also to the Roman. That cheap German kind which has been recently introduced should, if possible, be left severely alone—it is rubbishy. The best to use is the good fully and well-prepared cloth of the old London makers, and, with almost if not every one, it will be found, that although the price may be a few pence a-yard more, the saving of time and trouble, as well as the feeling of absolute certainty as to the result, will more than compensate for the difference. It is well, also, to be pretty fresh; old shop-keepers are apt to crack. In preparing to print, say, a head, or indeed any picture, it is better that the cloth be strained on its stretching frame and the position of figure roughly sketched in, there being no use to sensitise more than is really necessary, say, the head and shoulders, and hands, if they come in. By using either negative or transparency, the latter by preference, and projecting on the prepared canvas, the artist can at once see and place his subject where he wishes. Or, as is very often done, the artist simply sketches in the position he wishes for the principal portions which are to be printed, and leaves the rest to the photographer. This being done, prepare the canvas for printing in this way: Take in the proportions of—

Methylated spirits of wine	½ ounce,
Water, which need not be distilled	¾ "
Sodium chloride	3 grains,
Citric acid	1½ "

and with a sponge or piece of clean cotton rag rub and wash the canvas all over—back and forward—rubbing it lightly but firmly until all appearance of grease has been got quit of and the above salting solution lies quite flat all over, care, of course, being taken that the coating is equal, and that no pools or puddles are left on the cloth or panel, the surface being impervious to wetting.

The sensitising solution is—

Silver nitrate	35 grains,
Distilled water	1 ounce,

to which, in order to make it into ammonia nitrate of silver, add strong liquor ammonia until the brown deposit first formed is gradually dissolved away, leaving just a very few floating particles which are filtered out.

To sensitise the canvas, which should now have the subject chalked in if the sensitising is partial, but which is not needed if the picture is printed right out, proceed precisely as with the salting solution, using either a rag or sponge, either of which is much better than a Buckle's brush, and dry in the shade or dark room as rapidly as possible. When quite dry give another coating of the ammonia nitrate of silver, which it is also best to dry rapidly, and being dry is ready for exposure under the negative.

This, there being no possibility of getting such work into a printing frame, must be done in such a rough-and-ready or handy way as may suit each individual worker, but I have found the following a very useful method: Have a board prepared ready, with all the corners and angles slightly rounded off, and slightly thicker than the canvas stretcher, thus causing it to project above the general level; then place the board flat, the sensitised canvas above it, with the negative in its proper place and on which has been scratched a X at each of the upper corners, while at the lower edge any convenient strip of metal to act as a slight weight and keep things steady; a similar one may be used at the top edge while printing. The surplus sensitised surface is a pretty fair index of the exposure, but by removing the top weight and keeping the negative steady with the left hand, and raising the upper with the right, the X's will show when the printing is sufficient. The picture should be rather over than under printed.

There is no necessity for toning with gold or any other agent, and for the process of fixation make a fresh strong solution of hyposulphite of soda, probably about six ounces to the pint of water, and float it over, and when thoroughly fixed this will be made visible by the ease with which the silver image can be removed by the finger or a cloth. Now is the time to remove all superfluous silver stains, leaving only what is necessary for the artist's working upon.

The washing need be very slightly prolonged, as there is nothing to retain the hyposulphite of soda in the pores of the almost impervious paint of the ground.

If, however, at any time after the print has been finished it is found needful to remove any portion of it, or if any accident occurs during the work, such as a doubled image, or anything which spoils it as a print, the whole image may be easily removed and the canvas rendered as perfect as at first by the following method. Put into a bottle—

Spirits of turpentine	3 parts.
Methylated spirits of wine	1 part.

The two substances do not mix, but with a rapid shake they form an emulsion of a semi-opaque, white appearance, which, however, is not constant or persistent, as the two fluids, if left untouched, gradually separate, the lighter floating on the top of the other. This, however, does not matter for the purpose in hand. While it has the appearance of an emulsion, saturate the surface of a pad of woollen or cotton with it, and rub rapidly and lightly over the spoiled print, which will at once show symptoms of disappearing, and go right over the whole canvas, wiping with a dry cloth as it is proceeded with until the whole is removed. If the action is too energetic add a little more turpentine, and if too sluggish a few drops additional of spirits of wine.

After a final wash with water and a good rub with a dry towel the surface is again ready to begin *de novo*. It has been noticed that a failure once in a time may occur with a perfectly new canvas, but such a thing has never been seen on a second trial with the same canvas by the writer.

The same details apply to prepared panels for painting upon, or any other substance of a similar nature. Considerable care should be exercised in all the operations to prevent the damp or water getting on the back of the canvas or panel.

W. H. DAVIES.

COLOURED PHOTOGRAPHS. VIII.

In the last paper we discussed the various qualities of vermilion, pink madder, rose madder, Indian red, brown madder, cobalt blue, burnt sienna, Vandyke brown, and so concluded our most useful colours for the painting of flesh generally. We then passed on to gamboge, yellow ochre, and sepia; which leaves us now to consider lake, carmine, French ultramarine, smalt, indigo, and Prussian blue, thus completing the list of the most useful colours for painting, not only flesh, but also the necessary accessories for the production of a portrait picture. Taking the list up from where we left off, namely, sepia, we come to—

Crimson Lake.—As all things bright must fade in time, so it is with this beautiful colour. It has always been a source of deep regret to artists that the use of this colour was attended with such dreadful results in the future. It is a fine colour, but its permanency is more than in doubt; to be more correct, there is no doubt at all about it it is fugitive, and few, if any, colours more so. All colours deriving their beauty and brilliancy from their combination with cochineal must be always received as being most undependable. It is only used, as far as portraiture is concerned, in the draperies. Generally speaking, it may be considered more useful than carmine, although it lacks its extreme richness and brilliancy. It washes well, and is not so scarlet in hue as carmine. A coat of gamboge passed over it will render it slightly more durable, but then it changes its hue and produces a scarlet. Under ordinary conditions of exposure the progress of its decolorisation is slow, but if exposed to a strong light its disappearance is not only rapid, but complete. Crimson lake, although a colour universally in use with most of our water-colour painters, every endeavour should be made to dispense with it as far as is possible. This advice, although in a lesser degree, may be safely put forward as regards the use of gamboge and indigo as well.

Carmine.—A very rich, brilliant, and intense lake, and possessed of very great power in its fuller touches: its paler washes are possessed of considerable clearness. In the latter quality, however, it does not compare favourably with rose madder or pink madder, their paler washes being notable for their clearness and delicacy. It is easy to work, but has the fatal drawback of being fugitive. Indeed, we must consider this colour as one of the most fugitive when exposed to the influence of strong light. All experiments in this regard have conclusively demonstrated that the richness of this beautiful pigment is gradually, but surely, lost by exposure to the action of light. To place it under the influence of direct sunlight would be to annihilate it right away in a few weeks. It is seldom used now in landscape painting, being chiefly employed in illumination and flower painting. Like lake, it owes its beauty and richness of colour to cochineal, only more so, and, per consequence, is proportionately more fugitive.

French Ultramarine.—This colour is generally known as French blue, and may be described as an artificial imitation of the genuine ultramarine. When of the very best manufacture this French ultramarine is a very near approach to the genuine, and even has advantages over it, in as much as its washing properties are vastly superior. The very best French ultramarine will be found, as a rule, to be somewhat of a darker hue and to possess less of the azure than the genuine article. The superiority of the latter is incontestable as regards purity of colour, and this is no mean consideration, but it also possesses the

extra advantage of being immeasurably more transparent. French blue, as a pigment, is perfectly permanent, possesses, in a modest degree, the qualities and usefulness of genuine ultramarine, and may be regarded generally as a very useful substitute. The genuine ultramarine is prepared from *lapis lazuli*, a stone to be found in many parts of Asia, and is regarded as by far the most costly and celebrated pigment we possess. It is separated from this stone by a mechanical process as ingenious as it is tedious. The mineral, when thoroughly crashed, is mixed with a resinous matter so as to be formed into a thick paste. This is then skilfully washed with water in order to separate the ultramarine, the principle evidently assumed being that the resinous matter has more attraction and holding power for the particles of the stony matrix than for those of the ultramarine. There are two distinct portions of this ultramarine which separate themselves from the *lapis lazuli*. The first is by far the deepest and richest in hue, and manufactures into the genuine ultramarine. The second portion differs from this in hue, being of a bluish-grey colour, and furnishes the material to produce the pigment known as *ultramarine ash*. The genuine ultramarine, in its best manufactured form, is an exquisitely beautiful blue, by far and away the purest we possess. As a medium for the representation of sky and atmosphere it stands alone, without a rival, but, I am sorry to say, it washes very badly, a fact which is no mean consideration for an artist. As regards exposure to light, it may be considered permanently durable, but the atmosphere of modern towns, charged as it is with acids, may affect it considerably. Care should, therefore, be taken to preserve it against these evil influences. It does not mix with everything. It is seldom to be found among the colours in the box of a poor artist. It has a thorough knowledge of its natural worth, and demands its price. It may be regarded as the king of the colour box.

Smalt.—This colour is a vitrified pigment prepared from cobalt. It is a deep and somewhat purple blue, and is often used for shading other blues. It is rather difficult to work, being gritty, and consequently is more satisfactory when stippled than when washed. By artificial light it appears to be somewhat of a reddish-purple hue. It is an artificial colour, consisting, as it does, of glass coloured by oxide of cobalt until it becomes an intense blue; it is then ground until a powder of the proper hue is secured. In texture, as I said, it is gritty, and, as a natural consequence, washes badly. Exposure to light does not seem to affect it, but an impure atmosphere will cause it to become discoloured. I need not say that it would lose its beauty of colour as a consequence. Atmospheric moisture will have a like effect, as it causes a disintegration of the particles forming the pigment, which naturally must injure its beauty of hue. It is a useful colour at times for the background and draperies, but is mostly used for illumination and flower painting.

Indigo.—This colour is a vegetable pigment of a deep greenish-blue. It is a more than useful colour for backgrounds. It washes and works well. In conjunction with sepia it makes a capital retiring green for distant trees, &c. In the long, long ago this colour was called *Indian blue*, and is produced from the leaves of the *Indigofera* plant. It is much darker in tone than Prussian blue, although in hue it is somewhat similar. In depth and transparency it approaches very much towards Prussian blue, although not nearly so rich. As to the qualities of washing and general working, indigo stands well, but, if truth must be told, as a pigment it is anything but durable. It may, however, be found to stand fairly well under a moderate amount of ordinary diffused daylight. The durability of this pigment is greatly influenced by the amount of skill and care expended upon its proper manufacture. But all varieties of this colour, no matter how well produced, if exposed to the direct rays of the sun will be found to be fugitive.

Prussian Blue.—This is a very fine, intense colour. A very good shadow colour for draperies of a purple hue may be produced by a judicious mixing of this colour with lake. This colour was discovered many years ago at Berlin, hence its name "Prussian." It consists practically of ferrocyanide of iron prepared by precipitation. It possesses an immense body, transparency, and richness of colour; its deep washes are so intense as to almost appear black. Prussian blue is pervaded by a decided green tinge, and consequently is not a colour at all well adapted to painting skies and distances. One cannot call it a permanent colour, nor is one altogether justified in setting it down as fugitive. It has been known to stand very well, although exposed to ordinary daylight, but it fades to some extent if exposed in sunshine. On these points its manufacture is responsible for much. By exposure to damp Prussian blue will become discoloured, and contact with an impure atmosphere will cause it to lose its beauty of colour.

We have now more or less fully considered the various points of interest in relation to the qualities of the various colours mostly used in the painting of flesh and the ordinary accessories of a

portrait picture. I think, in the long run, it will be advisable, before proceeding with our subject, to continue our investigations as to the merits and demerits of the various colours until we have completed the list. We will then have, as it were, a dictionary of colours which will be useful for reference. I will, therefore, continue the consideration of the various colours in the following order:—Red pigments, orange, yellow, green, blue, purple, brown, citrine and olive, grey and black pigments. Of course, in doing this, we will not again touch upon those already mentioned, but direct our attention to those only of the same classes which have not as yet received our due consideration. Thus, under red pigments we will take scarlet vermillion, orange vermillion, Field's orange vermillion, pure scarlet, scarlet lake, madder, carmine, and dragon's blood, and not again touch upon vermillion, light red, Venetian red, Indian red, carmine, crimson lake, rose madder, or pink madder.

Scarlet Vermilion.—This colour differs from the ordinary plain vermillion already described, inasmuch as it is paler and more scarlet in hue. Its permanence and general qualities are quite the same.

Orange Vermilion.—This is paler still, and approaches more closely to the yellow. There is, however, more of the orange-red about it than the true orange. It is much more transparent, and washes far better than any of the other varieties. For landscape painting I think it can be safely considered as the most useful of all the vermilion we have yet considered.

Field's Orange Vermilion.—This colour will be found to have many very serious advantages over all others of its kind. All who have used any of the orange vermilion must have noticed the natural tendency which they have to separate. That is to say, there seems to be a heavier and deeper portion which sinks to the bottom of your well or saucer, and a paler or lighter portion which floats to the surface. It does not require much consideration to decide that this is a grave drawback. Field's orange vermillion, on the contrary, is a perfectly homogeneous pigment, which is obtained by a most elaborate process of levigation from the ordinary orange vermillion. It is much brighter and purer in colour than the latter, and, besides the obvious advantage of being free from the tendency to evaporate, it is also more transparent. It may therefore be considered, especially from the point of view of the landscape painter, to be the most useful of all the series.

Pure Scarlet.—This consists, chemically, of iodide of mercury, and is arrived at by precipitating a solution of mercuric chloride with one of iodide of potassium. It possesses all the body and opacity of vermillion, is immensely superior in brilliancy, but, on the other hand, immensely inferior in its permanence. There is, perhaps, no pigment so dazzling and attractive, and there is certainly none more fugitive. This is easily understood when we consider that the iodine and mercury which enter into its composition are both most volatile substances. Add to this the fact of its existing, like vermillion, in two allotropic modifications—scarlet and yellow. Indeed, this is a colour likely to change under the least provocation and from various causes. An impure atmosphere will rapidly blacken it; under almost any condition it will fade. Mix it with other metallic pigments, you utterly destroy it. A glaze of gum-arabic is supposed to add to its permanence, but only for a very short time. As a colour for landscape painting it seems altogether beyond the range of nature; the only product of nature which it can depict, as far as I can call to mind, is the flower of the geranium. For this purpose no colour can come near it; but in the ordinary way it is useless. For illumination and flower painting its attractions are quite irresistible, and that is, I think, the most good we can say of it. REDMOND BARRETT.

their formation on surfaces of normal silver. I have made these for comparison—pressing gummed paper on silver leaf, bringing to a smooth surface by gently rubbing after drying. The contrast between the pale and faded-looking effects produced on normal silver, and the lustrous and glowing hues given by the allotropic, is very striking.* One cannot help wishing that this splendid colouration could be made to do service for obtaining natural colours by photographic processes.

As to the durability of these products I cannot yet speak with positiveness. Protected from light and air they endure for several months at least. Both the bluish-green insoluble silver B, and the gold-coloured C produce these effects: the gold-coloured is the better suited of the two.

—*American Journal of Science* for September.

M. CAREY LEA.

“NOTES FROM NEWCASTLE.”

SIR,—We have had in Newcastle, I think, a surfeit of sciences and philosophy, fortunately some of us have been able to excursionise, otherwise the effect would be deplorable.

Though not a member of the body, I received invitations to the various meetings of the British Pharmaceutical Conference, and was much impressed by the manner in which the, for the most part solemn and dignified, members of the drug trade took their pleasure. At the *soirée* a fairly good show of photographs was made by Messrs. Mawson & Swan, who also, with Messrs. Brady & Martin, exhibited various electrical and other chemical apparatus. I suppose no one else was invited to contribute pictures, otherwise a much larger and more generally interesting show could have been made. At the Hexham and Rothbury excursion I met several amateurs and exchanged notes; three or four had their cameras with them, with what success I don't know. Mr. J. P. Gibson, the well-known medallist, won golden opinions from every one for his able and condensed description of the Abbey and its surroundings. Mr. Gibson also acted as one of the guides to the British Association excursionists on the following Saturday.

I don't care much for *conversazioni*, and that given by the Mayor and Corporation for the reception of the British Association at the Natural History Museum was no better than the average. The music was good, however, and I met several old London friends, so that an hour passed pleasantly. A good deal of hunting about brought me to the corridor where Mr. Muybridge gave his lecture and demonstration; accommodation had been provided for about one hundred, whereas about a thousand, apparently, were anxious to hear and see; however, two or three extra performances under better circumstances at the Central Exchange Art Gallery have fairly satisfied public curiosity.

All your readers will be pleased to hear that Captain Abney received the honorary degree of D.C.L. at Durham University during his stay.

From what I hear, at least twenty of the Associationists carried cameras, and some of them could show good work—the detective form being most popular with the rank and file. Writing about detectives, I imagine at least one hundred of the genus “Demon” to have been sold hereabouts lately—a large addition this means to the amateur department. I have seen and handled these five-shilling outfits, but never a photograph from them.

The Y. M. C. A. here, a thriving institution, has now its “Photographic Club.” The President is Mr. H. Crawford Smith. Vice-Presidents: Lieutenant-Colonel Crawford, Mr. F. R. Goddard, and Mr. James Bacon. Secretary: Mr. J. B. Duckett, of 9, St. James's-street, Newcastle. The subscription is five shillings, which includes the use of a capital dark room, hypo, dishes, developing trays, &c. Various meetings have been arranged and carried out successfully. An exhibition of work is expected to be held during the winter, and a prize will probably be offered for the best collection of slides—this looks business-like.

As a photographer I believe in *reproductions*, in this sense I append the following (from the *Newcastle Leader*), which will doubtless interest your readers:—

Scene: Street in Newcastle.

Austere philanthropist, who has just purchased a newspaper from a small boy: “How old are you, my boy?”

Boy: “Nine years, sor.”

A. P.: “What is your father?”

Boy: “Ah hevrent a fathor.”

A. P.: “What was he when he was alive?”

Boy: “Ah nivvor had a fathor.”

A. P. (with surprise): “Indeed! And what does your mother do for a living?”

Boy: “Ah nivvor had a muthor?”

A. P. (with greater surprise): “Indeed! And how did you come into the world?”

Boy: “Me aunt had a bairn tas the lodger, an' ah'm him!”

The British Associationists go in rather for frivolities at times, especially in the Anthropological Section. The Anthropometric Laboratory has been well attended, and amongst other interesting items elucidated is this, that males squeeze seventy-two pounds, and females forty-five pounds. There must be something wrong here, as I know several young photographers who could squeeze anything up to 130 pounds or so!

My remarks about the local society were certainly rather strong, but I

ON RING SYSTEMS AND OTHER CURVE SYSTEMS PRODUCED ON ALLOTROPIC SILVER BY IODINE.

ALLOTROPIC silver, in its moist and plastic state, may be brushed over paper, and gives, on drying, a continuous and brilliant coating resembling metallic leaf. When a small crystal of iodine is placed on paper that has been thus coated, a system of coloured rings of remarkable beauty is obtained. A funnel or beaker should be inverted over the paper to prevent distortion by irregular currents of air. One form of distortion, however, produced by a slight current in one direction gives interesting results. If the paper with the crystal on it is set near a closed window, the slight current which makes its way through affects the air under the glass enough to carry the iodine vapour principally in one direction, and there result oval or pear-shaped curves of great elegance and much variety, according as the air currents are stronger or weaker. Another method is to place a bell glass, not fitting too closely, over the paper, and to set it where it will be influenced by the draught created by a fire, or even a gaslight.

That iodine is capable of producing interference rings (Nobili's rings) on metallic surfaces has long been known, and Robert Hunt has described

don't think ill-natured, nor out of place. It is annoying to see a society so little alive to its own interests as this. During the last two or three weeks it has had exceptional opportunities for making its existence known to and appreciated by numerous visitors. There might have been one, at least, of the social meetings Mr. Proctor describes; and an outdoor meeting would not have been out of place; while a public demonstration of lantern slides would have been a godsend. Its members could have met and conversed and exchanged ideas with members of other societies, to their mutual advantage. For all practical purposes the Newcastle-on-Tyne and Northern Counties' Photographic Association has been dead during the last few weeks; however, let us hope for better things in the future. Any suggestions I may have to make must be "contained in our next."

D. D.

Our Editorial Table.

MASON'S "ARTIST" MOUNT.

MESSRS. GEORGE MASON & Co., Glasgow, have sent us samples of a new class of mount they are introducing. It is a grey Bristol board with India-tinted centre. It is suitable for every class of photograph, and the specimens sent us entirely bear out their claims. These comprise everything in the realm of portraiture, groups, landscapes, and engineering. There ought to be, and will be, a large demand for these useful and attractive mounts when brought under the notice of the public.

TRADE CATALOGUES.

SEVERAL of these are before us this week. The most voluminous is that of Messrs. Holmes, Sadler, & Holmes, Manchester, who, in a ponderous tome of 206 pages, show with numerous illustrations the great variety of productions that they are capable of supplying. Indeed, on looking through its pages we are at a loss to find any photographic requisite that has been omitted.

Fallowfield's *Monthly Remembrancer and Traveller*, for August and September, too, is well supplied with every-day requirements in the way of cameras, stands, developers, and the numerous things requisite in the practice of photography.

Taylor, Taylor & Hobson, of Leicester, send us the eighth edition of their catalogue, which is ever increasing in dimensions and an exposition of their growing manufacturing business, in the development of which no effort or expense seems to have been spared. Their speciality, as every one knows, is lenses.

CONVENTION GROUPS.

ONE gloomy evening, when the cessation of rain rendered it possible, the party who, during Convention week, visited Kew Observatory assembled outside the building, and before departing on their homeward journey were photographed by Mr. Thomas Scotton, of Derby. The result is before us, admirably executed, and we shall treasure it as a memento of an afternoon spent in company of a most genial party.

From Mr. Richard Keene (Derby) we have received a copy of a group taken by him at Gravesend during the excursion of the Convention to that old seaport. It is a free-and-easy group, containing most excellent likenesses of many whom we know and esteem. With Mr. Keene's group he sends us also a picturesque view of Morton Old Hall, Cheshire, showing the entrance gateway from the south-east. This, like the other, is printed in platinotype, in which this veteran artist excels.

INDEX OF PHOTOGRAPHIC EXPOSURES.

MR. A. R. WORMALD (Sutton, Surrey) sends us the new edition of his *Practical Index of Photographic Exposures*, which has now got into its fourth thousand. Its object, as stated, is to supply to the beginner in photography a ready means of knowing (without calculations, or with as little calculation as possible) the duration of exposure likely to produce a good negative with a given stop and plate.

REVOLVING SPIRIT LEVEL.

MESSRS. SHARP & HITCHMOUGH, Liverpool, send us one of their Aptus revolving spirit levels, which they have recently introduced, to be attached to the revolving back of a camera for the perfect adjustment of the horizontal; when the back is reversed the level is revolved at right angles to indicate the horizontal in the altered position.

I was desirous of having some of these curve systems reproduced in colour printing for this *Journal*, but on conferring with an experienced colour printer found that he could give no assurance of a successful result. The colours are transparent, and yet have a metallic brilliancy—a combination almost impossible to imitate in printing.

When the level is placed on the top of the camera it takes the place of an ordinary circular spirit level, it having the advantage of an easy

adjustment. The diagram shows its nature. The idea is a good one, and the level will prove useful.

PATENTS COMPLETED.

IMPROVEMENTS IN APPARATUS FOR THE EXHIBITION OF PHOTOGRAPHIC PICTURES, ADVERTISEMENTS, AND THE LIKE.

No. 14,089. JOHN TAYLOR LEIGHTON, 18, Montgomery-street, Edinburgh.—*August 17, 1889.*

My invention relates to improved means for the exhibition or display in succession of photographs, pictures, advertisements, and the like, which being mounted upon suitable frames, are by the rotation of a handle brought successively into view.

The improved apparatus or appliance according to my invention comprises an enclosing box or frame, divided into three compartments or divisions, the central one of which is shallower than the others, but of sufficient depth to allow of the free passage of the frames. At the top and bottom of the enclosing box are fixed, horizontally, four grooved or slotted plates, two at the back and two at the front, within which grooves move horizontally and parallel to each other four slides, each provided with a loose projecting clutch or pawl, which latter may, under some circumstances, be held in position by means of springs or equivalents. The two front and two back slides aforesaid are connected respectively to two vertical bars arranged within one of the lateral divisions or compartments above referred to. Said vertical bars have longitudinal slots formed therein, in which slots take the crank pins of two adjustable revolving arms, the rotation of which is effected by means of a knob or handle fitted upon the exterior of the enclosing case; thus, upon rotating said handle, a to-and-fro motion is imparted to the vertical bars and its attachments.

The frames above mentioned are formed of any suitable material, and provided on one or both sides, as may be desired, with clamps or grooves for holding the articles to be exhibited or exposed to view. In a convenient position on the top and bottom of the frame and front and back are formed slots, perforations, or recesses, with which engage the loose clutches or pawls fixed to the slides aforesaid. The vertical edges of said frames are bevelled in such a manner that in the forward movement of one frame it may pass in front or to the rear of the next succeeding frame.

The action of the improved apparatus, according to my invention, is as follows:—Upon rotating the knob or handle the arms aforesaid, on which are fitted the crank pins, are rotated in unison therewith, by which means, as above described, the vertical bars and horizontal slides have a reciprocating motion imparted thereto. In the forward movement the loose clutches or pawls of the back slides engage with the perforations or recesses in the back plate of the frame, impelling it forward from the centre division into the outer or third lateral division or compartment. In its return the clutches aforesaid are capable of sliding over the perforations or recesses in the back of the frame, but the clutches on the front side, now engaged with the recesses in the front of the frames, and by means of the bevelled edges, withdrawing the frame to a rearward position in the central compartment or division.

In addition to the clamps or grooves in the frames, small springs may be employed to retain the articles to be exhibited in position and prevent displacement during the to-and-fro motion above described.

The enclosing box may be of any suitable design, ornamental or otherwise, and may be provided with a magnifying lens inserted in a collar attached to the front of the box.

In cases in which the frames are intended to carry two photographs or other articles, the back of the enclosing box is provided with an opening similar to that in the front, and may similarly be provided with a magnifying lens, thus allowing double the number of articles to be exposed to view than when the front only is utilised.

IMPROVEMENTS IN THE CONSTRUCTION OF PHOTOGRAPHIC CAMERAS.
No. 12,573. WILLIAM SCORER, North-street, Havant, Hampshire. —
August 31, 1889.

My invention relates to improvements in photographic cameras, and consists of a device for the easy adjustment of the swing back and the easy closing of the camera with the focussing glass, which is protected by the lower part of the said camera.

By means of my invention, a camera is capable of being easily fixed in position, while its rigidity and the safety of the focussing glass are thereby ensured.

In carrying my invention into practice, I make a folding and sliding base, or frame, upon which is fixed the back and front of the camera carrying the bellows, this camera being either square or conical in shape.

The central part of this base, or frame, which carries a support resting upon the tripod stand, is provided either with a tongue or groove on which the outer portion slides, and which can be moved away from the lens with the back. The said tripod stand can be fixed in an ordinary manner, or provided with a toothed circular turntable actuated by a pinion. To the front part of this frame is hinged another part of sufficient width to carry the whole of the camera when closed, and provided with a suitable clamp thereunder, by means of which it is firmly fixed to the said front part, enabling the camera to be opened or closed with facility.

This second part is of suitable length and thickness to correspond exactly when open with the outer portion of the sliding frame, which is provided at its lower part with a groove, in which slides a metal piece. Upon this piece pivots the back of the camera, which can be thus extended and clamped in position, and can be made to swing backward, forward, and sideways. Upon the frame constituting the back of the camera is screwed another metal piece, and the former pivots upon the metal piece before mentioned, which slides under the frame, and is clamped in position by means of a suitable clip. The said metallic piece carrying the back of the camera can be made in one piece, or, in the case of large cameras, in two pieces, connected, when the camera is open, by a strip of metal, being secured in position by one or more milled-head screws.

The camera frame is also furnished with a screw for separating the sliding portions thereof, and is used for focussing after a rough adjustment by means of the above-mentioned sliding piece.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 19.—Mr. H. M. Smith in the chair.

The CHAIRMAN said that at a meeting of another Society it had been stated that if a finished bromide print that was found to be too dark were treated with oxalate developer and immersed in hypo it would be reduced. He had tried it, but without sufficient result to be sure of it, and inquired of Mr. Debenham if he could throw light upon it.

Mr. W. E. DEBENHAM supposed that it would depend upon whether the oxalate developer had become oxidised, as it would be with an old developer. In this case, no doubt, it would reduce the depth of the print.

Mr. A. HADDON agreed with this view, and added that if the oxalate were fresh and neutral, and the hypo contained silver, the print might be expected to be rather strengthened than reduced.

The CHAIRMAN said that the gentleman who made the statement with which he set out had added that a print developed with pyro would not be reduced, but only an iron-developed one.

Mr. DEBENHAM: This was a case of mistaken observation, of which there were many instances in photographic history, these mistakes being accepted as facts by subsequent writers, and stated as such in text-books.

The CHAIRMAN had an instance in his mind illustrating that remark.

A question was read:—"What is the best medium for mounting silver prints in a book so as not to cockle the leaves?"

It was replied that a medium should be used, such as gum or starch, containing as much alcohol as possible, and that the print should be dried before being covered with the medium.

Mr. ARCHER CLARKE said that it was best to starch the prints and let them dry; fresh starch might then be applied, and if quickly laid down the cockling would be but slight.

The CHAIRMAN mentioned that Mr. Zaehnsdorf had said that he always pasted paper on the back of a mounted photograph, so that there should be a tension to counteract that which arose from the contraction of the print in drying.

Mr. F. A. BRIDGE said that he curled prints backwards for a time to cure the curl.

Mr. DERENHAM said that the remedy was only good for a time, and that the print would eventually curl inwards.

Another question was read, asking for a reliable formula for preserving sensitised paper.

Mr. P. EVERITT recommended floating the back of the paper on a bath of citric acid solution at a strength of nine ounces to the gallon.

Mr. DEBENHAM inquired whether paper so prepared toned well.

Mr. EVERITT replied that it did very well.

Mr. DEBENHAM remarked that of the acids he tried the only one which preserved the paper without interfering with the tone was perchloric. This might be added direct to the sensitising solution.

Mr. CLARKE recommended storing the paper between sheets of blotting paper that had been imbued with soda.

Mr. HADDON said that in some cases sensitised paper yellowed more quickly between blotting paper than without it. That was due to a small quantity of hyposulphite of soda left in the paper by the manufacturer.

Another question was asked as to the best method of mounting prints on boards having an India-tint lithographed centre, the member inquiring having found a strong tendency in the prints to come up after drying.

Mr. BRIDGE said that if the tint were sponged over with water it would afterwards take the starch paste properly.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

SEPTEMBER 17.—Mr. J. Traill Taylor (President) in the chair.

The Hon. Secretary showed some 8x6 platinum type prints of views in the Isle of Wight.

Mr. G. J. Clarke showed some silver prints, and Mr. W. Bishop some hand-camera views.

The CHAIRMAN referred to an alleged new cure for blistering of albumenised paper, the method being to immerse the print in alcohol; this was published by Mr. Stuart, of Glasgow, in an article in *THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC* in 1878. The cure consists, after toning and washing in water, in immersing the prints for a short time in methylated spirits of wine till such time as they have a semi-transparent appearance, or about five minutes, then press most of the spirit out and wash again in water.

Mr. H. M. SMITH did not think it necessary to immerse in neat spirit, and suggested the addition of spirit to the toning or fixing bath, in the same way as it might be added to the developer for bromide prints.

Mr. A. MACKIE said that at a meeting of the Photographic Club it was agreed that the size left the paper, and not the albumen the size.

The CHAIRMAN said that he had examined the inside of a blister under a microscope, and found filaments of paper attached to it, proving that the size had left the paper.

Mr. MACKIE said that if there were a tendency in the paper to blister, it would be brought on by a sudden change in the temperature or density of the solutions.

The CHAIRMAN stated that a sudden change in the density had a great deal to do with blistering, and in America it was usual to place the prints in salt and water after the hypo bath, to make a gradual change in the density.

Mr. CLARKE had used a very weak solution of acetic acid before fixing.

The CHAIRMAN said there was an objection to the use of acetic acid, as, unless it was washed entirely out before fixing, sulphur toning would result.

Mr. MACKIE did not think that the same theory held good in the case of blistering on bromide paper.

Mr. BISHOP considered that there was a closer relation between the processes than was generally supposed, and thought the methylated spirit would harden the size of albumenised paper in the same way as the gelatine film of bromide paper, and prevent its tearing away from the paper.

Mr. SMITH said that, albumen being soluble in ammonia, he considered the use of ammonia in the fixing bath would soften the albumen film and favour blistering; he had known cases in which paper had blistered when ammonia was used that had not blistered without it.

The CHAIRMAN stated that the heavier the coating of albumen the worse the blisters would be should the paper have any tendency in that direction.

The next meeting will be on Tuesday, October 1, when the Hon. Secretary will read a paper on *The Relation between Exposure and Development and Subsequent Improvement of Negatives*. Visitors are invited.

PEOPLE'S PALACE PHOTOGRAPHIC CLUB.

SEPTEMBER 20.—Second annual meeting.—Mr. W. Lindell in the chair.

The SECRETARY read the Committee's report, which showed that there were forty-two members on the register. The winter's programme had been contributed to by papers and demonstrations. By the Secretary, on *The Carbon Process*; Mr. Edwards, on *The Platinotype Process*; Mr. Farmer, on *Modes of Development*; Mr. Livingston, on *Intensification and Intensifiers*; Mr. Downing, on *Flash Light Photography*; Mr. Hastings, on *The Work of Photographic Societies*; Mr. Gamble, on *The Preparation and Use of Isochromatic Plates*; Mr. Hawkins, on *The Wet Plate Process*; and Mr. R. Beckett, on *The Measuring of Lenses*. A social meeting and two public lectures had been given.

At the Workmen's Exhibition, held at the Palace, of the five first-class certificates awarded four were carried off by members of the Club—Messrs. Barrett, S. J. Beckett, Edwards, and Hawkins.

At the City Guilds Examination, of the thirteen students that passed ten were also members of the Club.

The report then stated that the Trustees of the Palace had decided to suspend for twelve months the Institute portion of the Palace and also the Clubs formed in connexion therewith, and that they should be dissolved as from September 30 instant. The Trustees, however, would be prepared to consider any application to form new clubs from students in connexion with the technical schools. Having regard to the progress made and flourishing condition of the Club, the Committee regretted any circumstances that rendered the disturb-

ance of the Club necessary, but trusted that arrangements would be made by which no present member would, in the event of their not joining the Photographic Club be refused membership in the new Club.

The SECRETARY, in moving the adoption of the report, explained fully the arrangements decided upon by the Trustees, and recommended the meeting to adjourn until October 3, when the Club could, *pro forma*, dissolve, and immediately afterwards reform, when the officers could be elected and the Club be re-established.

This course was agreed to.

The Auditors' statement was read, and showed a balance of 2*l.* 1*s.* 4*d.* in hand.

BATH PHOTOGRAPHIC SOCIETY.

THE last of the regular excursions of the season took place on the 21st instant at Glastonbury Abbey.

By noon many exposures had been made upon portions of St. Joseph's Chapel, the Abbey walls, crypt, &c., such as were favourably lit, but the wind blew too strong to do justice to heavy foliage. Accordingly it was decided to visit Wells, some six miles distant. Here the sun was shining brightly, and some work was done in the quaint old market-place, then in the full swing of a market day, its rapid streams of water running each side of the street, probably for centuries, as an overflow from a powerful spring in the Bishop's Palace grounds, and reminding one of abroad, at Lima for instance, where water passes along a wide channel in the middle of the streets to the outskirts.

The west front of Wells Cathedral is, on a sunny afternoon, one of the most satisfactory subjects of the kind which can be photographed. This and several other portions of the exterior received attention, especially the cloisters, Vicar's Close, and moat. No work could be done inside owing to service being conducted at the time. About half-past five we bid adieu to this cathedral city, reaching Bath about two hours later.

Correspondence.

Correspondents should never write on both sides of the paper.

ISOCROMATIC PHOTOGRAPHS.

To the Editor.

SIR,—Mr. Bothamley, in his paper on *Orthochromatic Photography with Gelatine Plates*, which appears in the *BRITISH JOURNAL OF PHOTOGRAPHY*, August 30, page 571, says, "Ives's method consists of flooding the plate with an alcoholic solution of the dye (containing one grain in four ounces), allowing the alcohol to evaporate, and then washing with water. It is not easy to see why this method should give better results than simply immersing the plates in an aqueous solution of the dye. Photometric experiments confirm this supposition. They also confirm Ives's statement that if the plate is treated with the strong alcoholic solution and not washed, no sensitiveness to the less refrangible rays is obtained, doubtless because the alcoholic solution does not really penetrate the film. I was unable to get satisfactory results with cyanine in this way."

Mr. Bothamley's conclusion, although discrediting one of my statements of a certain and demonstrable fact, is undoubtedly the result of a conscientious trial of the method. It is, therefore, fortunate that I am now able to give the probable reason for Mr. Bothamley's failure, and to state the conditions of success so plainly that he will be able to repeat the experiment successfully. These conditions, as I now understand them, are as follows:—First, that dyes be used which are either insoluble or not freely soluble in water; second, that the sensitive plates be of a suitable character ("seed" plates and some others are suitable), and that they be fresh from the factory.

After making, possibly, forty splendid negatives by this method with cyanine, I opened a box of plates of a different size, which had been some months on a shelf in my dark room, and with these plates got, by the same method, only weak, foggy, worthless negatives, although the plates worked all right for ordinary photography. Further experiments showed that my method was decidedly better than Schuman's more complicated bath method on some plates when they were fresh from the factory, but not so good as Schuman's when they were old, and not better than Schuman's with some makes of plates, even when they were fresh. The fact remains that the best results I ever got with cyanine were by my own method, and that the relative colour sensitiveness was far greater than had ever been reported from the use of cyanine on such rapid plates.

I believe I have already called attention to the fact that cyanide and chlorophyll, when applied in the manner I have recommended, appear to remain entirely upon the surface of the film, even when the plate is soaked in water. It seems to me that the water acts only upon the dye to render it light-sensitive, and that this "sensitised" dye, when further altered by exposure to light, forms a nucleus for development, in the

manner suggested by Captain Abney (*BRITISH JOURNAL OF PHOTOGRAPHY*, 1888, pages 196, 215). In fact, I believe we have here a proof that Captain Abney's theory of the action of colour-sensitisers is correct, but that his demonstration was incomplete, and the method he recommended was unsuccessful because he did not recognise the necessity of treating the dye with water to make it light-sensitive.

That the failure of cyanine and chlorophyll to make plates colour-sensitive without wetting is not due merely to their failure to penetrate the film, as assumed by Mr. Bothamley, is proved by the fact (to which I long ago called attention) that they act in the same way upon collodion plates, which must also be wetted after applying the alcoholic solution.—I am, yours, &c.,

FRED. E. IVES.

Philadelphia, September 11, 1889.

CONTINUATING ACTION OF LIGHT.

To the Editor.

SIR,—There are some slight typographical errors in the article under this heading, a few of which please let me correct. The second word in the last line of the first paragraph is a travesty. The word "fraction" in the next paragraph should be in the plural, while the comma after "is," line 17, paragraph 3, mars the meaning of the sentence. The punctuation mark after "exposure," line 9, paragraph 4, should be deleted, and "as" read for "are." For these and the rest I, no doubt, am to blame.

The continuing theory was, I find, advanced by a writer in the *ALMANAC* about ten years ago, and was promptly doubted by so considerable an authority as Dr. Eder.—I am, yours, &c.,

THOMAS BEDDING.

MISAPPLICATION OF PHOTOGRAPHIC LENSES.

To the Editor.

SIR,—I regret that your correspondent, Mr. Larry O'Broom, has not understood my paper. The ambiguity he finds with regard to my opinion on large direct heads as against enlargements from small ones may be due to the fact that I took it for granted that every photographer was well conversant with the bearing of the law of conjugate foci on the subject. As a matter of fact, however, your correspondent does not quote me fully, his quotation being from the following sentence:—"I do not propose to discuss here the *pros* and *cons* of direct large heads as against enlargements, for there are many other reasons coming in which, at the expense of theoretical benefit, have proved that the direct large head, when taken under the most favourable circumstances, that is, with a lens of long focus, is undoubtedly much more pleasing than an enlarged small image." To endeavour to make this clearer to your correspondent, I simply repeat what I then said with reference to the accompanying diagrams.

Fig. 1.

Fig. 2.

In Fig. 1, if the object O and the image I are arranged at double the focal length of the lens on opposite sides of its optical centre, they are of the same size. Any object O¹ or O² nearer to or farther from the object O, will necessarily give an enlarged or reduced image respectively; and in taking a given life-sized head, if the eye be focussed for, the nose must be enlarged, and the ear or background reduced in scale. Now, if a long-focus lens be employed to do this work, any difference in the planes other than those focussed for becomes less and less apparent as regards truth in the resulting image. The longer the focal length of the lens, the less and less apparent becomes the liability of untrue rendering. In Fig. 2 the rays meet the lens practically parallel, and if a small lens, such as a *carte* lens, be employed in focussing a sitter at such a distance that the rays are practically parallel—i.e., the difference between the extreme conjugate points included is insignificant in comparison to the distance of the sitter from the lens—a theoretically truer image in drawing is the result, and if this be enlarged to the same size as a direct large head it is theoretically truer in drawing. As to the question of distortion,

a rapid rectilinear or any non-distorting lens—including some forms of portrait lenses—gives the truest drawing. The Petzval form of portrait lens is next, and the ordinary single achromatic meniscus last. I concur with your correspondent that an enlarged head from a negative taken with a rectilinear lens is to be recommended for fidelity of reproduction; but my own opinion is that enlargements have a kind of "flat" appearance that does not appear in a properly taken direct large head. Your correspondent informs your readers "the pleasing results (in direct large heads) are not gained with the lens, but with the printing process." This may have something to do with the subject, but it is quite out of the question to ignore the performance of the lenses in the question.—I am, yours, &c.,

THOS. R. DALLMEYER.

25, Newman-street, W., September 25, 1889.

To the Editor.

SIR,—In last week's JOURNAL I see a letter from Mr. Larry O'Broom anent the above subject. I have read it over twice, and it still appears to me quite misty. I really cannot see why he should say that "the pleasing results are not gained with the lens, but with the printing process." Surely the kind of result *should* be due to the lens used in producing the image, whether this be from a projected small image, as when enlarging, or whether it be a direct large image, i.e., an image produced in the camera by means of a lens whose focal length is not less than twice the length of image required. I have gone through the various papers read at the Convention, and consider those by Mr. Dallmeyer and Mr. Traill Taylor to be the most practical on the subject that have appeared for some time; and I am sure that if the professional photographer made it a rule to work according to Mr. Dallmeyer's ideas, he would produce his large pictures more natural than he does now. There are a few professionals alive to the great advantage gained by using long-focus lenses of both single and double form when they wish to produce large heads, &c., but the present rule is to use the *carte*, cabinet, and other lenses for pictures that would be infinitely better were lenses of greater focal length used. With regard to *distortion* by lenses, I, some years ago, when gelatine plates first came into use, made the following experiments on the stereotyped model of former days, viz., the plaster bust recommended by our dear old Jabez Hughes, and other writers, for the collodion worker.

From this bust negatives were made by means of lenses of the following types:—Rapid rectilinear, portrait, single landscape, portable symmetrical, and, lastly, the lens from the finder of an astronomical telescope. All were of the same focus within a fraction of an inch—that is to say, the same size of image was produced with each lens without altering the distance between it and the bust. Transparencies were made—by contact—from the negatives, and these were projected upon the usual screen by means of the limelight, but no difference whatever could be seen in their outline. The picture produced with the finder objective was as perfect as the one made with the rapid rectilinear, the result being no doubt due to using long-focus lenses, and at a sufficient distance from the model to practically bring the focus down to nearly that for parallel rays. Had I used lenses of greatly different foci, and made the images agree in size by altering the distance between camera and model, I believe that I should have discovered distortion in the picture made with the shortest-focus lens, because of the exaggerated perspective produced.

It is some time since the practical W. K. Burton recommended for large portraiture single lenses of long focus. Such lenses, however, were made, and have been obtainable now for several seasons. Still, the pity is that photographers do not avail themselves of such excellent tools; the simple fact is, the majority of them do not give themselves the trouble to read and understand such practical papers as those given at the late Convention.—I am, yours, &c.,

J. T. CHAPMAN.

Manchester, September 23, 1889.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—Mr. Robinson makes merry with quip and quotation over what he terms my "definition" of naturalism as "truth and the best of everything," and he confesses himself a naturalistic under this description. This astonishes me, for later in his letter there is yet another quotation to affirm that what he wants is truth with some fiction or imagination added.

Now in the rage for definitions I should like to ask Mr. Robinson for his definition of imagination or "fairy fiction," just to see how far from *untruth*, as far as our art is concerned, this would turn out to be. No two men agree as to what is truth in the abstract, but a very general consensus of agreed opinion will be found to exist as to many things being *untruths*. Amongst these *untruths* must certainly be included the results of combination printing as practised by Mr. Robinson, wherein the character, quality, and tone of the foregrounds will be found to be out of harmony and truth with the backgrounds, wherein also, in many cases, the artificiality of the models reminds one of the stage rather than of the country. Mr. Robinson, with some boldness, defends the practice of photographing ladies trained to carry out his ideas, and dressed up as rustic maidens or fisher lasses, as being better than trusting to haphazard

chance for models. But it is no question here of chance, because the artist who takes such pains as Mr. Robinson does, would naturally carefully select his model to the manner born for any special subject. A very short study of photographic pictures, comparing those containing figures dressed for the occasion in unaccustomed garb and posed in unaccustomed actions, with others in which figures native and natural to the surroundings and subject they are depicted in, are taken, will convince any one on this point. Lady models are not in place in such subjects, and no skill can make them so. It may be more comfortable to work in this way, and easier to attain a certain end; but, unfortunately, "truth and the best of everything" will not admit this practice in the way it has been followed.

Mr. Robinson objects to my claim as to what it is which differentiates the ordinary from the naturalistic school, but he practically admits the claim in his next paragraph. He joins issue only on the word "exclusively," and boasts of adding imagination. Now this to me means absolutely nothing. Surely the poetry and pathos, and all that makes nature most beautiful to the seeing eye, is *in nature* as she appears to us all, and has to be drawn from it by the artist who is trained to the powers of expression, not added from without. Where the imagination comes in, in such daring combination printing as Mr. Robinson is famed for, is beyond me to see. Let any one look at *The Angelus* or *The Sower* for a lesson.

I echo Mr. Robinson's desire to stop disputing over terms, but there is something more than mere terms involved where it is a question between, on the one hand, combination printing, over emphasis of so-called composition laws in minutiae (such as rules about wedge-shaped lights and shadows, and balancing lines in detail), attempts at historical subjects, and artificial models, and, on the other hand, severe regard for everything natural and true in tone, costume, action, and expression.

It may readily be admitted that the aim and desire are the same in both cases, but the divergence is as to methods and principles admissible and likely to lead nearest to the desired result.—I am, yours &c.,

GEORGE DAVISON.

MISLEADING FORMULÆ.—EIKONOGEN.

To the Editor.

SIR,—I am a lover and user of ten per cent. solutions, and on the advent of the new developing agent, eikonogen, obtained from a leading dealer here an original tin of it. I attempted to make a solution of my pet strength, but quite failed to get a stronger solution than about three per cent. On seeing in your issue of last week that Messrs. Fradelle & Young state that they make a ten per cent. solution, I have tried once more, and failed as before. On going to the dealer about it, he tells me that I might as well attempt to put a quart of ale into a pint pot as to try to make a solution according to Messrs. Marion's advertisement. Who is right?—I am, yours, &c.,

JAMES GARDNER.

Manchester.

[Our correspondent will not succeed in making a *plain* ten per cent. solution, but if the proportion of sulphite of soda given in the formula issued by the makers be just dissolved, it is possible the desired quantity of eikonogen will be taken up, as its solubility is greatly increased in the presence of the sulphite.—ED.]

CAUTION—EIKONOGEN.

To the Editor.

SIR,—I may be allowed to caution all those using Thomas's hydroquinone developer not to do so in a metal tray, as the caustic potash necessary to that developer acts fatally upon the gilding or plating of the tray, and on cleaning it or rubbing it the brass surface is quite exposed. Can any one suggest an easy way of rendering this surface innocuous, either by replating or otherwise? The developer in question, which is a very excellent one, has no action upon vulcanite or porcelain.—I am, yours, &c.,

ETHEL CONSTANCE MAY.

A USE FOR GELATINO-CITRO-CHLORIDE PAPER.

To the Editor.

SIR,—I ask for space to describe what is, so far as I know, a new use for the paper mentioned above. It is, briefly, for the reproduction, either on the same scale, or on a scale either larger or smaller, of negatives.

Such reproduction is generally done, at least in this country, by the taking of a transparency from the original negative, and the production from that of a second negative. This process is troublesome, and never, in my experience, gives a second negative quite equal to the original, even if the transparency be in carbon. I do not say that it is possible to get a reproduced negative quite equal in gradation to the original, but I have no hesitation in saying that I get better negatives by copying gelatino-citro-chloride prints that have been stripped from glass than by making them from transparencies.

The copying of prints that have been stripped from glass is very easy on account of the complete absence of grain. It is only necessary to so place the print and the camera that no reflection from the surface of the former is to be seen when looking from the position of the latter.

Negatives are very liable to destruction in this country from climatic influences, and I find it quite worth while, in the case of any negative that I specially value, to make, at the beginning, a print on gelatino-citro-chloride paper, and to store this, in case of accident to the negative.

It might be thought that the tone of the print would much influence the result in copying, but I find that it does so to but a small extent. On the whole, I prefer a brownish tone.

It is often recommended that a transparency should be made from any negative that is specially valued, in case of accident to the latter. It is at least quite as useful, and much easier, to make a print on gelatino-citro-chloride paper.

I have written throughout of gelatino-citro-chloride paper, but I imagine that a burnished print on any other kind of paper would serve equally well.—I am, yours, &c.,

K. OGAWA.

Tokio, Japan.

THE CORNWALL EXHIBITION.

To the Editor.

SIR,—It says a good deal for the work of an amateur that it should deceive the eye and judgment of the skilled representatives of the foremost photographic journals in the world; but so it has been in the case of one of the exhibits at the Royal Cornwall Polytechnic Society's Exhibition, 1889, noticed in the JOURNAL for September 20, where the lantern slide studies of Mr. F. Briglemen are quite coolly put down as being "printed evidently by a mechanical process of various tones, which are very effective and fanciful." As it so happens, I had the privilege of examining that "frame of lantern slides" before they were sent away, and since that time have carefully examined others from the same worker's hand, as well as the negatives from which they were taken, and, to clear up that little mistake once and for all, must state that the gentleman alluded to is an amateur of the studious and practical type, with little time to spare from his professional duties, and that those slides are prepared and printed by himself, without his having even the knowledge of how to print, or get them printed, mechanically. The dozen of slides sent were made by the following processes:—Gelatino-albumen (Chapman's), which were the only commercial plates used; the others were by gelatine citro-chloride, gelatine bromide, and carbon, all prepared by the exhibitor.

The different tones and colours of the silver prints are got entirely by exposure, development, toning, and fixing, these operations being so varied as to get the different effects of sun or moonlight, the greeny-blue of the latter (although quite untrue to nature) being that by which we are wont to represent nature in paintings. If there is any doubt about the untruth of moonlight colour, just take a look at trees or foliage during a full moon on a cloudless night, at, say, twenty yards distance, when it will be seen that the most colour-sensitive eye will fail to detect even a vestige of colour. All nature is seen then as "darkness dimly lit."

In the two or three carbon slides, the thickness of the material may have led to the mistake of supposing them mechanical, but closer observation will show that they are highly artistic, both in selection of subject and production of print from the untouched negatives. It may be noted that prints from several of these and others obtained for Mr. B. a special medal at the Crystal Palace Exhibition in the spring of the present year.

In this connexion it might be suggested that lantern slides should not be looked at only as prints, but be judged by their appearance on the screen, the same lenses and light being used.—I am, yours, &c.,

Edinburgh, September 24.

ARTHUR SEAT.

STANDARD MEASUREMENTS FOR PHOTOGRAPHIC LENS FITTINGS.

To the Editor.

SIR,—I had no opportunity of explaining to you at the Convention my course of action in the matter of those standards for lenses. You were absent when I moved the return of the report, and it occurs to me that you might misunderstand me. There is already much deplorable misunderstanding connected with the whole concern, and so I write you.

My simple reason for moving that Mr. Wollaston's report be not adopted was that I believed it to be no report of any work done by the Convention Committee, which I understood had never met; and that in its incompleteness and grossly bad expression, it was altogether disgraceful to the Convention, and impotent.

As you know, I and my firm do heartily support the general adoption of the series of screws and the system of apertures recommended in the report. But I felt, and do now feel, most strongly, that if the work of our Convention in the matter is to command that high respect, which it should merit, and which the thing itself demands, we must do the work in some far better way.

I myself do know the correct specification of the standard screws, for instance; but I do not think you could find six other men who do. And you cannot understand it from the report. So also in other matters: the whole thing is to my mind extremely feeble and impotent. I do not care personally that our opticians themselves have not been consulted. If

the work had been done at all well, I would not care who did it. But I do feel annoyed that the one who professed such enthusiasm at Birmingham should have so damned it himself.

This is one view of the matter—a most important view—which is most imperfectly considered. No optician is likely of his own generous will to abandon his old screw fittings. It means an enormous loss of plant and stock.

Whatever system may ultimately become common will be established by public demand chiefly. Public demand is the only thing possible for his conversion, or for any general agreement.

And you, good sir, with your vast powers, have it more in your hands than any of us to make the healthy public demand.—I am, yours, &c.,

State-street Works, Leicester, September 15, 1889. WILLIAM TAYLOR.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Eight new porcelain dishes, 19x16 and downwards; wanted, whole-plate lens in exchange.—Address, H. T. AULT, 15, Wharfe-street, Newcastle, Staffordshire.

I will exchange enlarging lantern, four-inch condenser, for 12x10 portable camera with one or more double backs.—Address, ARTIST, 75, Dale-street, Batley Carr.

Will exchange Brown's patent whole-plate combination camera with two double slides for lantern and slides.—Address, G. A. ROBINSON, East Bank House, Hawick, N.B.

I will exchange a cabinet No. 3 portrait lens with Iris diaphragms, by Beck, for first-class studio furniture or a whole-plate outdoor outfit.—Address, W. DAKIN, 1, High-street, Sheffield.

A genuine Beeston Humber Crippler tricycle, light roadster, suitable for either sex, offered in exchange for light 15x12 or larger camera and lens.—Address, PHOTO, Museum Parade, Matlock Bath.

Wanted, a single landscape lens by Ross, four inches diameter and twenty inches focus, in exchange for tanks, &c., for carbon printing, a whole-plate patent Globe lens, seven inches focus, and Wilson's Quarter Century in Photography.—Address, H. C. J., 7, Tadema-road, Chelsea, S.W.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

J. Bell, Frome.—Photograph of Memorial Cross, St. John's Churchyard, Frome.
Photograph of North Porch, St. John-the-Baptist Church, Frome.

B. B.—Wash for half an hour.

A. B. C.—The publisher does not know.

M. A. H.—Both hot and cold bath are utilised for the purpose.

R. J. SHERMAN.—Dissolve pure or non-vulcanised rubber in benzol.

RUSSELL STEELE, M.D.—Any lens having a focus of from twenty to thirty inches will do.

J. GOTTHARD.—Try a hydroquinone developer, such as that lately recommended by Mr. J. W. Swan.

C. C. W.—The arrangement described will afford sufficient light of a good quality for copying.

W. H. McENTER.—There are two German weeklies—*Deutsche Photographen-Zeitung* and *Photographisches Wochenblatt*.

H. W. J.—As you say, one patent appears to be an infringement of the other, consequently that last taken out will be invalid.

J. WIDDER.—Judging by the specimens, there is merit enough in the process to render it one that would be taken up by lithographers.

EIKONOGEN.—It is at present on its trial; a little time will suffice in having its alleged advantages established, or otherwise. We have not yet received the pyroxyline.

F. H. K.—England Brothers, 6, St. James-square, Notting-hill, W., are the publishers. For other works, see "Editorial Table" notices in this JOURNAL during the present and past few years.

A. A. A.—The reply you received was certainly very stupid. It was probably written by a clerk who was totally ignorant of the practical part of the subject with which he was dealing. Write personally to the manager.

W. HERBERT asks where he can purchase some blood albumen, as he cannot obtain it at any of the photographic warehouses.—It may be had from most drysalers. Skilbeck Brothers, Upper Thames-street, we know supply it.

WINTER PHOTOGRAPHY.—If the electric light is not available, the best substitute in portraiture is magnesium. This may be used either as the flash light or by burning the ribbon. The limelight is not sufficiently actinic for taking portraits.

ANTHONY BEALES.—We are not acquainted with either of the lenses named, but their respective rapidities will easily be ascertained by comparing full aperture with focus. That which has the shorter focus is the quicker working, both having equal apertures.

EIN FRAGER inquires: "What is the best method of putting the names of views, &c., upon the negatives? are they printed or written with a pen?"—The best and most usual way is to write the names with a sable pencil charged with a black varnish, such as "Bates's black."

P. C. B. DANIELLS.—The outlines of the albumen process will be found on page 470 of the current volume. Full working details have been given several times in back volumes, also in the ALMANACS. We cannot in this column spare the space to give the practical details of processes.

R. SHIRLEY.—The best and cheapest method of reproducing the manuscripts will be by photo-lithography. We can offer no opinion as to whether their publication would be likely to prove a commercial success; all will depend upon whether the sporting fraternity take sufficient interest in such matters.

T. NORTHERN asks: "Will you please inform me if there is any way of restoring a negative over-intensified with mercury to its previous condition?"—Immerse the negative in a solution of the bichloride of mercury until the image becomes whitened, then stop the operation as soon as the image becomes thin enough.

A. S. says: "I have had the misfortune to break a glass positive I had to copy. Can you give me an address of a photographer who makes glass positives?"—There are several photographers in the neighbourhood of the Westminster Bridge-road who take glass positives. Most itinerant photographers work the positive process almost exclusively.

K.—We cannot congratulate you on the work; all the portraits are flat and map-like. This is due to using far too much front and top light. Try the effect of stopping out all the front light and softening the top light; then illumine with the side light. The form and proportions of the studio are very good. The fault is not in the studio, but in your method of working it.

YORKS inquires where he can obtain brown paper in very large sheets, like that upon which some of the backgrounds are painted. The largest sheets kept by stationers, he says, are much too small for his purpose.—Our correspondent should apply to the upholsterers; they keep brown paper in continuous lengths, and about five feet wide. It is sold under the name of "carpet paper."

BROMIDE writes: "Will you kindly let me know the qualifications necessary for employment under Government as a photographer?"—We presume the only qualifications necessary are the requisite abilities to do the work required. The Government, however, employ very few, if any, civilians as photographers, most of the work being done by the military—chiefly by the Royal Engineers.

W. JAMES.—In photographing groups of dahlias, you will gain a considerable advantage from the employment of orthochromatised plates and a yellow screen. You cannot do better than prepare the plates according to the formula given by Mr. Bothamley, as you suggest. Use as little light as possible in the dark room during the preparation and early stage of development of the plates.

L. M. says: "I should like to know what is the experience of your readers with regard to Carbutt films. I took about eight dozen abroad with me this summer, and most of them I found stuck to the paper placed between them, and in many cases the paper between them was crumpled or doubled up. When stuck together I pulled pieces off the film. Considering the price charged, I think they ought to be sent out in a better condition."

C. WOOLSTON says he has some writing to copy, but he cannot succeed. It is written in a blue ink on a very yellow-tinted paper, and, he adds, the difficulty is in obtaining sufficient contrast between the writing and the paper, no matter by what process he intensifies the negative.—This is a case where orthochromatic photography will prove of special value. Our correspondent should use an orthochromatic plate, and expose through a tolerably strong yellow screen; he will then obtain a satisfactory result, without doubt.

ARGENT BROMIDE writes: "By mistake, in the dark, I took a bottle containing ammonia bromide instead of the nitrate of silver bottle and dropped a small quantity into the sensitising bath (for floating paper) before I discovered my mistake. Can you help me out of my difficulty or suggest the best plan to adopt with the bath?"—No harm has been done; the bath has only been weakened by some of the nitrate being converted into bromide of silver. This must be filtered out and the bath made up to its original strength.

INQUIRER writes as follows: "I shall be glad if you can give me advice in your 'Answers to Correspondents' in regard to an Eastman film negative I have. The negative, when washed, was placed on a piece of glass, film down, and on drying did not peel off as usual. I should like to remove it from the glass altogether, or, failing that, to strip the paper from the back. Failing either of these plans, what would be the best way of making a reproduction?"—If the negative be on stripping film, our correspondent has proceeded wrongly. The glass should have been collodionised before the negative was placed upon it; then the application of hot water would have removed the paper. If the film is so firmly adherent it is possible that hot water may still cause the paper to come off; if this does not succeed the best way will be to reproduce the negative by transmitted light in the camera.

N. C. COOK.—The cause of the indistinctness is due to a movement of the camera during the exposure. Probably the stand lacks stability. This is the fault with many of the exceptionally light and portable stands.

Z. A.—You will not be able to successfully etch a copper plate through an exposed gelatine film with nitric acid. The acid would destroy the film. For this reason a solution of the perchloride of iron must be used.

RECEIVED.—W. Scover; and others. In our next.

PHOTOGRAPHIC CLUB.—At the next meeting, Wednesday, October 2, the subject for discussion will be, *Backgrounds and Appliances for Home Portraiture*.

THE Jones patent smoke consumer, or "Fumu Dejector," is said to be useful in manufacturing towns in keeping the atmosphere clear from smoke. Everything that tends to abate the smoke nuisance will be cordially welcomed by photographers.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—Competition Prints and Lantern Slides. All pictures and lantern slides to be addressed to the Hon. Secretary, and deposited at 3, Lord-street, not later than two o'clock on Thursday, 28th November, after which time none can be received. The rooms will be closed to members on that date from half-past two until half-past five p.m.

Illustrations, Mr. Francis George Heath's magazine of amusement, art, literature, and science, commences its fifth volume in October with a new pictorial cover, and its forthcoming issues will include illustrated papers, embracing drawings of the month, reproductions of the National Gallery pictures, pretty places, art studies, eminent artists, pen and pencil portraits of celebrities, Tyrolean winter resorts, &c. Simpkins, Marshall, Hamilton, Kent, & Co., are the publishers.

PICTURES BY PHOTOGRAPHY.—An exhibition of photographic pictures by Mr. H. P. Robinson, of Tunbridge Wells, will be opened at the Camera Club, 21, Bedford-street, W.C., on Friday, October 4. Mr. Robinson's landscape photographs are well known in the country, and this exhibition will include a representative collection of his work. There is at the present time a considerable stir amongst photographers to claim for their art pictorial possibilities which have been very generally denied it. This series of exhibitions serves to bring forward examples of the best that has been done by the camera. The pictures are open to inspection by visitors interested on presentation of card.

"WHAT have you in that covered basket?" severely asked the watchman, in "Plutarch," of the slave. "It was covered," pertly replied Doalos, "in order that you might not see what was in it." Detective Parsons, being in Aldersgate-street, saw a person carrying a parcel, and looking about in what, to the detective mind, seemed a suspicious manner. "What have you in that parcel?" demanded the officer. The person declined to say, but subsequently explained that it was only some old lead. The contents of the parcel were examined by a jeweller, who pronounced it to be silver, weighing 7½ ounces, worth 3s. 6d. an ounce; and the person was charged with the unlawful possession thereof. But behold the untrustworthiness of circumstantial evidence! When the accused came up on remand at Guildhall his brother-in-law deposed that the silver was his own property, being the residue of nitrate of silver used in baths for sensitising photographic paper, of which article he was a manufacturer, and that he had given the silver to his connexion by marriage to sell for him. So the innocence of the accused being established he was discharged. —*Telegraph*.

ANIMALS IN MOTION.—We learn that the lectures and demonstrations by Mr. Eadweard Muybridge have been greatly appreciated in Newcastle-on-Tyne both by the members of the British Association there assembled and by the people generally. The *Chronicle* says that much interest has been created in Mr. Muybridge's extraordinary manifestations with his Zoopraxiscope, which has been well described as a magic lantern run mad. Mr. Muybridge's first appearance in Newcastle at the Mayor's *conversazione* on Thursday last week did him little justice, as he could not be heard in the corridor to which he was relegated, nor could the wonderful pictures that he throws upon the screen be properly seen. In the Art Gallery, however, seeing and hearing were accomplished without the slightest difficulty, and the audience were delighted and astonished at the marvellous demonstrations of animal locomotion that were brought before them. Animals walked, cantered, galloped, and leaped over hurdles in a perfectly natural manner. All sorts of beasts and birds were illustrated in various stages of locomotion, and, finally, man appeared on the scene, and reproductions were given of the *genus homo* walking, running, leaping, tumbling, and performing all sorts of extraordinary antics in a manner that was absolutely lifelike. The entertainment was instructive and unique, and there can be little doubt that Mr. Muybridge has got hold of an idea that should have an important influence on art in the future. He has since repeated his lecture in the Art Gallery.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1535. VOL. XXXVI.—OCTOBER 4, 1889.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE present Exhibition of Photographic work is one of which this Society may very justly be proud, inasmuch as it gives unquestionable evidence of progress in art study; and we cannot but think that the general opinion will be that this year's display of photographic productions will most undoubtedly raise the art capabilities of this scientific method of producing pictorial results. It is a very singular fact, that just in proportion to the progress made on the side of science, so the artistic possibilities also seem to be increased; this, to a very great extent, may undoubtedly be attributed to the freedom from that anxiety and subsequent mental worry which attended the usage of the comparatively old wet process, for the mental quiet and absence of consideration for possible failure in this respect after, in many instances, so much thought and care had been bestowed on the preparation of a picture (more especially where living objects were studied) must leave the operator perfectly free to give full scope to his actual capabilities.

Therefore, we acknowledge with strong emphasis the debt which we owe to science for the present pictorial and most gratifying result of photographic investigations.

Perhaps the most noticeable advance is in the character of the portrait exhibits, which show a decided tendency to the avoidance of those rather outrageous accessories which, not so long ago, seemed to be the accepted stock-in-trade of so many otherwise good workers. A study of those exhibits in portraiture which have totally eliminated accessories, having only plain backgrounds, will reveal this fact which so many of the highest portrait painters have always adopted; thus the attention of the beholder is at once fixed upon the real subject matter, viz., the head and face, and in many of the large direct photographs in the present Exhibition this result will be readily acknowledged.

There are but few exhibits of pictorial subjects where figures have formed the leading study. This, which is the greatest of artistic capabilities, demands a very high appreciation of form and constructive skill, both in detail and in their relation to accessories; therefore, much praise must be given to those exhibits which show that by photography this highest of pictorial results can be realised.

One of the scientific aspects of this Exhibition arises from the very large number of platinotype prints which this year are in evidence of the capability of this process, not only to record delicate detail, but also to eliminate so much of those intense dark masses which attended its first introduction, and thus this wonderful union of science and art is steadily progressing towards perfection, and consequent higher position in pictorial results.

Not so much progress can be recorded of another scientific

matter, viz., the absolutely true rendering of colour by photography, and by that is implied the actual measurement by one colour of the entire scale and relation of many colours in their true advancement and valuation when translated into white and dark.

This matter at present is somewhat like an infant, no doubt progressing most satisfactory, but requiring time to develop into maturity.

One very curious matter is most prominent in this year's display, and that is the almost universal usage of plain oak frames, and, in many instances, large white mounts. It has been frequently remarked that this is a retrograde movement, which gives to the pictures an appearance of being simply a collection of engravings. The hitherto cold black tone of the platinum work seems to have suggested this mode of framing, whereas a gold frame in contact with the photograph, without question, not only suggests the idea of *original* work, but also gives more value to the enclosed matter. A careful study of those pictures which are in gold frames undoubtedly reveals this fact, and it is a great pity that this mode of framing could not be enforced in some way. Two things would be gained by so doing—one being a most powerful help to the photograph itself, the other an avoidance of those masses of light which so distract the sight and lower the tone and pictorial effect of the exhibit. A walk round the Exhibition, to realise the full effect of this depression of the photograph by its surroundings, should most certainly lead to a different method of framing. In some instances a darker toned mount has been used, which at once increases the artistic value of the photograph.

Despite this drawback the Exhibition is exceedingly interesting, and marks an onward movement both in the scientific and artistic aspects, the greatest of which is the marvellous outcome which photography now reveals, viz., that besides being a thing of beauty, it is becoming possible that it may also be a joy for ever.

There are some excellent specimens of photo-engraving processes, which appear to make greater progress every year.

There can be no question but that the re-introduction of medals on the part of the Photographic Society has resulted in a large amount of very excellent work being sent in, although there is the absence of many well-known exhibitors; and hence it seems to have been considered necessary to display as much as the Gallery can contain, so that a full and most assuredly an attractive Exhibition is the result.

This year's Exhibition will, then, well repay the thoughtful attention of those who wish to profit by the advancement made in science, and also to study the realisation of art possibilities which photography hold out.

The Jurors this year were Messrs. W. Bedford, Valentine Blanchard, George Davison, William England, Joseph Gale, H. P. Robinson, and J. Traill Taylor. They awarded the medals as follows:—Lyddell Sawyer (84, *Dangerous Company*); B. Gay Wilkinson (99 and 101, *Shrimping and Prawning*); A. Schmitz (129 and 638, *Cologne Cathedral and Staircase in Royal Castle, Cologne*); F. M. Sutcliffe (136-7-8, *Fish Stall, Saturday Afternoon, and Dinner-time*); Green Brothers (178, *Head of Derwentwater*); Ralph W. Robinson (413, *et seq.*, *Sir J. E. Millais*, and other home portraits of artists); Harry Tolley (447, *Carting Hay*); Robert Faulkner (480, *Professor Blackie*); Typo-Etching Company (494, *Sleepy Hollow*); Auto-type Company (498, *Christians fleeing from Persecution*). In the Apparatus Division, to Swinden & Earps (666, *Detective Hand Camera*); and for Transparencies, to F. P. Cembrano (678).

The pictures by H. P. Robinson, J. Gale, and G. Davison, who were Judges, were not entered for competition.

We shall next week begin the detailed notices of both the pictures and the apparatus.

HOME-MADE CHLORIDE OF GOLD.

We have discussed the question of the manufacture of nitrate of silver and shown that for the average photographer to attempt to make this salt, even counting labour as costing nothing, and ignoring possible breakages and the cost of utensils, not to speak of the purchase of nitric acid, is something less satisfactory than the traditional "change for a shilling." We have now to inquire how the matter stands with regard to chloride of gold. On this point we have not to do with the theoretical proportion of gold in a hypothetically pure gold salt. We have to find out what the product as placed upon the market is, and to calculate from the data so obtained. There is here no trouble at all; the best brands of chloride of gold have, without exception, we believe, a printed label stating the amount of metallic gold contained in a given quantity of chloride—whether so-called "chloride of gold" or "chloride of gold and sodium," &c., is immaterial, as we have practically to do with the precious metal alone.

"This tube is guaranteed to contain seven grains of metallic gold," we usually read on the fifteen-grain tubes: if the salt is purchased in bulk the reference is still generally to the proportion in fifteen grains. It will, therefore, for the purpose of our remarks, be advisable to deal with this amount, the fifteen-grain tubes being familiar to every one. Eighty-five shillings being the value per ounce of unalloyed gold, we get $85s. \times \frac{7}{15} = 39s. 8d.$, the value of the gold in an ounce of commercial chloride of the brands alluded to, or $39s. 8d. \times \frac{1.5}{4.50} = 1s. 2\frac{1}{2}d.$, the value of the metal in a fifteen-grain tube.

Our readers may now judge for themselves whether, at the price they pay for this necessary chemical, they would find any economy in what we may term home-made chloride. As a matter of fact, it may be estimated that, buying the gold salt in bulk, it would have to be bought in large quantities to get it at such a price as to stand the purchaser less than twenty-five per cent. increase upon the value of the contained gold. Put in another way, a pound's worth of metal dissolved made into chloride would be charged at a minimum of twenty-five shillings.

If the photographer desired to produce the salt in the form of clean crystals anyway resembling the commercial article, it may at once be said that unless quantities far beyond the

ounce or two likely to be dealt with were to be used there would be loss, as the time involved would be considerable, and the production of clean crystals is so difficult except in bulk.

In the case of this salt, however, the crystalline form is less necessary and less called for than with nitrate of silver. Most photographers keep it in solution, and when they purchase a fresh supply dissolve it in a given proportion for stock, and measure rather than weigh their quantities. It is easy enough to dissolve a metal and keep the solution, and therefore it is not nearly so uncommon for photographers to make their gold solution as it is their silver nitrate crystals. When this is done it is usual to take coin of the realm—sovereigns rather than half sovereigns—dissolve in *aqua regia*, and use without further preparation; or to precipitate the gold, so as to eliminate the copper, and re-dissolve. This latter operation involves very considerable time, and a certain risk of loss, as precipitated gold takes a considerable time to entirely fall to the bottom of the precipitating jar, and any hurry would result in the fine, precious particles being lost.

If, however, the solution, just as it is made from the coins, be employed, the saving is quite appreciable, and there are many who employ such solution and consider it quite equal to that made from the commercial salt. There is the objection that a considerable amount of chemical foreign to the salt is introduced in neutralising the highly acid product obtained in this manner; but we are not aware that it has been found to have any detrimental effect. It has been stated that the chloride of copper is injurious to the tone of the print; but when the solution is neutralised with carbonate of lime the quantity of that salt will not be found great.

In conclusion, we may say that home-made chloride of gold, from the dissolution of sovereigns, is useful and economical; but otherwise the manufacture is more satisfactorily relegated to the laboratory of the practical chemist.

NUKTIGONIA—what a nice name to be sure! But what is it, and what does it mean? Simply this, that according to the "Anti-Dark-Room Photographic Company, New York," a certain something has the property, when mixed with the developer, of enabling plates to be developed in open daylight. Even such an authority as Napoleon Sarony, of New York City, is found to say that "the great want for amateur photographers has been supplied by the Anti-Dark-Room Photographic Company, and it is most ingenious and simple. We are not informed as to the nature of this new addition to our resources, but remembering that we have exposed a plate undergoing development in ferrous oxalate (which is of a deep red colour) to light while the developing action was going on, and this without impairing the quality of the resulting negative, we are led to inquire if "Nuktigonia" be not a red dye which has no deleterious effect upon the developer when added thereto.

WHEN the platinotype and the bromide paper processes were, commercially, in their infancy, not a few surmised and gave vent to their impressions that the cold colour of the pictures and their dead surface would be an insuperable bar to their success. It will be remembered that at that period we strongly and steadily advocated the adoption of the cold tones and matt surface for the better kind of pictures, and prognosticated that eventually platinotype and bromide paper would supersede silver printing for the higher class of work. In this opinion, we may add, we stood pretty much alone. How far our prognostications have been verified each succeeding Exhibition has amply demonstrated. The present one, however, far exceeds every previous one in the number of photographs of the engraving-like character. Indeed, many of the examples, mounted on India paper and plate-marked, are scarcely to be distinguished from veritable engravings.

Furthermore, some of them have decidedly more force and vigour than some of the photographic engravings shown. The garish, red-toned prints on albumen paper, so much in vogue at Exhibitions a few years back, now appear to be conspicuous by their absence.

A CORRESPONDENT, an amateur photographer, writes complaining of the scant courtesy he received from many professionals to whom he applied for the loan of a dark room wherein to change his plates, or to develop a test negative occasionally, during his holiday tour. He says in the majority of instances he was refused, although he offered to pay something for the accommodation. Various excuses were made, such as—it would interfere with business, sitters were expected, the rooms were engaged, &c., notwithstanding that in many cases there were no sitters to be seen. This is not the only letter of a similar character that we have received during the past few weeks. At first sight it does appear to be somewhat churlish to refuse the use of a dark room for the brief time necessary to change half a dozen plates. But a little consideration will show that this small accommodation even may, in a busy establishment, entail considerable inconvenience during business hours. On mentioning the subject to some provincial photographers, now in London for the Exhibition, they one and all declared that the visits of amateurs were little less than a nuisance during the busy season. The mere changing of a few plates, which need occupy but a few minutes, usually entailed the loss of an hour or two in gossiping; the amateur must see over the place, put a number of questions on all manner of photographic matters, to say nothing of the many suggestions made, all of which have to be treated with courtesy. One gentleman said he recently gave the use of his developing room and chemicals to an amateur to develop a couple of trial negatives, and although he had sitters waiting, it was over an hour and a half before he could gain access to it again. When he did, he found it in such a state that it was impossible to work until all the benches had been cleaned down. The solutions, he said, "had been spilt and splashed about everywhere, dishes left dirty, and hypo was all over the place." This gentleman declared that another amateur should never have the use of his dark room. If amateurs, when they are accommodated, would always bear in mind, and act accordingly, that in a photographic business time is money, they would, as a rule, have no cause to complain of want of hospitality on the part of their professional brethren.

We have frequently referred to the exceedingly low price at which carbon prints on opal glass—the "porcelains" sold at the fancy stationers—are produced. One would have thought that these pictures were cheap enough in all reason with this method of production, but evidently it is not the case. We recently saw in a shop window some silver prints on albumenised paper of the scrap genus, mounted on opal glass. Although, we imagine, they had not long been made, they had faded badly. The evil appeared to be brought about by the mountant used to stick them on to the glass. This, in some instances, had given way with the heat of the window, and the paper was peeling off. In the same window were to be seen some chromo-lithographs, also mounted on opal, after the style of coloured carbon pictures. The race after cheapness is now very keen, but up to the present time carbon holds its own, so far as cheapness, combined with general effectiveness, is concerned.

PHOTOGRAPHERS at holiday resorts often complain that the varnished lithographs, in imitation of photographs, sadly interfere with the sale of their views of local scenery. Usually these lithographs are sold in long strips bound up in a cover. A few days ago, however, we were shown some of the cabinet size mounted on thick chocolate colour mounts, with gilt and bevelled edges. These pictures, for the most part, will be purchased by the public under the impression that they are veritable photographs. It is scarcely necessary to mention that they were of foreign production, although they bore no indication of the fact. Here, again, is evidence that the Trade Marks Act is not being complied with.

In exhibiting specimens in showcases too little attention is frequently paid to the glass of the frames. The tint of this may, and often does,

materially alter the tone of the pictures, and sometimes has a marked influence for the worse on the appearance of coloured work. How often it happens that the tone of a print appears perfect itself, but when it is framed, by reason of the colour in the glass, it is sadly disappointing!

THERE is another point in connexion with the exhibition of pictures which is frequently overlooked, namely, the light in which they are shown, or which may occasionally fall upon them. This was well exemplified a short time back, and in the following way:—Several very fine bromide enlargements were exhibited in a shop window, and one day, when the light was feeble, it was noticed that they all appeared to be in places of a decided yellow tint, just such a tint as was highly suggestive of sulphuration in the fixing. The pictures were on the point of being removed, when it was noticed that the yellowness was caused by the light from some pale, stained glass above the shop window proper. A few sheets of brown paper laid upon the top of the window-case at once restored the pictures to their pristine whiteness. In a bright light the pale tint of the stained glass was overpowered by the strong light coming direct through the window, but not so when the light was feeble. In the windows of some reception rooms tinted glass is introduced for decorative purposes. When this is the case considerable care should be exercised in the hanging of the pictures, otherwise, in coloured work especially, they may be materially deteriorated in effect by the tinted light which may happen to fall upon them at different times of the day.

WITH much gratification we learn that the high honour of the Order of St. Stanislaus has been conferred by His Majesty the Emperor of Russia upon Mr. Leon Warnerke for his "useful activity and special researches and improvements in the art of photography in Russia." Those who in this country know Mr. Warnerke, and are acquainted with his researches, will not fail to be struck by the justice with which this award has been made.

PHOTOGRAPHIC AWARDS AT THE PARIS EXHIBITION.

THE English awards are now published. In the classification, photography has not found a place among works of art, but is relegated to the Industrial Section.

Upon examining Class 12, "Photographs and Photographic Apparatus," we find that the following are the recipients of the honours:—

In Photographs the list stands as follows:—W. J. Byrne, *Bronze*; Jas. Burnside, *Bronze*; Frith & Co., *Silver*; J. P. Gibson, *Silver*; F. Hollyer, *Silver*; James Lafayette, *Silver*; H. S. Mendelsohn, *Silver*; J. B. Scott, *Bronze*; F. M. Sutcliffe, *Silver*; John Thomson, *Gold*; H. Vanderweyde, *Gold*; Walery (Count Ostrorog), *Gold*; Werner & Son, *Silver*; West & Son, *Silver*; York & Son, *Bronze*.

In the Photographic Apparatus Section the medals are awarded to—J. H. Dallmeyer, *Gold*; Ross & Co., *Gold*; Sands & Hunter, *Silver*; J. F. Shew & Co., *Silver*; and Watson & Sons, *Gold*.

DEER STALKING WITH A CAMERA.

THIS, at first sight, seems a strange subject for a non-sporting paper, but I will endeavour to show that it may be one that will interest some of the many photographers who glance over these lines.

Science has developed two methods of shooting—one which destroys the object shot at; the other which permanently secures the object, either as a thing of beauty for ever, or the reverse, to the confusion of the shootist.

The second method will interest photographers more than the first, and it is to be understood that this method of shooting—which perpetuates, not destroys—is the one adopted in this short account.

As deer stalking with a camera is a somewhat new development, it is to be hoped that a few of my brother photographers will take advantage of my experience and try their hands at obtaining pictures of these most graceful animals during this and next month.

Highland deer are hardly fit subjects, for obvious reasons, so we must content ourselves with stalking tame deer in our public parks.

This method will be found as interesting in its way as the more expensive, and it is quite as necessary to be very wary in our approaches to this game.

Walking through Richmond Park last autumn I passed close to a large herd of red deer, which was under the management of a most magnificent stag. This old fellow was so occupied in keeping his herd together that I went quite close to him, well within range; standing alone, with a small oak in the background, he made a study worthy of Landseer, particularly when he laid his great head back and bellowed to some of the wayward herd. I was in a splendid position, light correct, distance good: all things combined to produce a rare picture, but, alas! I had no camera.

This year, again, another splendid chance occurred. Walking through the park with my dog, a Russian wolf-hound, perambulating ahead I caught sight of a solitary red doe, walking with head erect and stepping as if on stilts: it came towards us with such apparent uneasiness that, remembering that the deer had only lately been suffering from rabies, I felt a little uneasy also. She continued to approach until within three yards, when we all came to a standstill and mutually admired each other. I had by this time discovered that the dog was the object of this unusual display of interest on the part of the doe, who every now and then lowered her head in a threatening manner towards him; so I called him to heel and thought it wise to proceed slowly on my way, as the doe made no sign of moving off to a safer distance. As soon as we started the doe started and followed close behind. Suddenly, when not thinking of her, I heard a rush behind, and the dog took to his heels, followed by the doe uncomfortably close. After they had careered round in a large circle I managed to call the dog to heel again, and we proceeded rather more rapidly than before, leaving the doe looking anxiously after us. This doe, I found, had lately deposited its fawn in some bracken close by, and so resented our too near approach to its lair. Thus, as my camera was reposing at home, I lost a second splendid opportunity of shooting a deer standing alone.

Next day I went on what I guessed would be a wild goose chase—no, a tame deer hunt—and passed the same spot with my camera and dog, but no deer were in sight. Returning home I came across a herd of red deer, and determined to try and stalk them with the help of the dog.

In the ordinary way it would be of no use to approach a herd of deer boldly, for they would be off long before a sufficiently near position to shoot had been reached, but during the "fence months" they have a special interest in dogs and are not so timid. The months most suitable for this kind of work are May, June, September, and October.

I ought, perhaps, to say that my camera used for this work is quarter-plate, and of the detective kind, with a lense of five inches focus. It is possible to get shots at deer with a very long-focus lens in an ordinary camera and focussing cloth, but the depth of focus is not sufficiently great to obtain the best results, and stopping down is not permissible to any extent with a rapid shutter.

My method of procedure was as follows:—I and the dog approached slowly; if they showed any sign of retiring we stopped, and I became deeply interested in my black box: my movement interested them, and they stood still and stared. When they became settled we again slowly approached, stopping as before when necessary. Having by this means come almost within range, I altered my tactics, and having set my camera for action, and focussed for ten yards, I tucked it under my arm, and telling the dog to "lay down," moved slowly away from him, keeping the same distance from the deer. When I had gone some steps, the deer, watching intently, began to walk towards the dog with hostile intentions. When they were close to him I called him, and, telling him to lie down again, walked a few paces, approaching the deer imperceptibly. They then made for the dog again, and by this means we gradually came within range, then, allowing them to compose themselves into a picturesque group, the trigger was pulled, and the deed of darkness done—for was not the "black art" employed? If a second shot should be required, with a change of position, the deer stalker should move slowly away from the ground he has been working over, and allow the deer to approach the places where the dog has been lying. This they will do before he gets out range, and begin sniffing around and looking inquisitively at the dog, who is innocently lying at your feet, snapping at the flies, and not even bestowing a thought on his would-be assailants.

A most important point to be observed in thus stalking deer, is to be slow and deliberate in all movements. A sudden move will probably cause a stampede in the opposite direction required, and then it will be as well to find another herd to operate on, for by the time they have finished their run all interest in you and your proceedings will have evaporated, and you may try in vain to get within

range again. Don't be in too much hurry: surely a really good picture is worth an hour's patient work.

To possessors of tricycles there remains yet another way of stalking deer, available any time of the year; and although much still remains for care and skill, it is, perhaps, the easier method *when* the deer are found. In parks the deer have become quite accustomed to traffic along the roads, and take but little notice of passing vehicles, even though they themselves are almost on the road. Often when riding round Richmond Park, without my camera, I have come across most picturesque groups quite close to the road, some even being upon it. If the tricycle is brought slowly to a standstill near such a group, they will look up, but show no intention of moving off, and being well within range—if not almost too close—they can be secured without any trouble.

A little account of an attempt in this line will illustrate the mode of action.

One day in August I rode into the park with my camera fixed behind the tricycle, and passed those places I considered the best; however, the deer were browsing anywhere but near the roads, and after having gone some considerable distance I was almost giving up for the day, when, in the far distance, I just distinguished an object on the edge of the road which looked uncommonly like a deer, so putting on speed, lest it should be gone before I reached the spot, I soon neared it; as it had moved several times during my approach, I was pretty sure of my game, but I was soon disillusionised—it was only a man and woman seated with their backs towards me! On my way home, however, I was more successful; this time I made no mistake, several fine stags were slowly crossing the road near some hawthorn trees some distance ahead. I stopped, took my camera from behind the tricycle, mounted with it under my arm, and rode quickly towards them. On nearing them, I slackened speed and approached very slowly, and finally came to a standstill in a good position and pulled the trigger. If care is used, one may turn round after riding on a little way and come back for another shot. No attempt must be made to dismount and walk by, as they will move directly on hearing footsteps; the shot must be taken while seated.

There are some disadvantages attending this method; for instance, one is entirely dependent upon good fortune for coming across a group by the roadside, and if one does meet with several sufficiently near, the light may be in the wrong direction; in this case it is best to keep back and wait a little while until they cross the road, which they are almost sure to do.

A hint as to the time of exposure may be of value to those who know the speed of their shutters. If taking a single deer, a speed of one-tenth of a second is safe if the operator waits until it stands still. For groups it is best not to use less than one-twenty-fifth of a second, as some are sure to move their heads.

The best times for the tricycle are in the morning or evening on ordinary week-days; it is of little use on holidays.

Permission to photograph in the Royal parks and gardens may be obtained from the Chief Commissioner of Public Works and Buildings, 12, Whitehall-place, W.

W. P. ADAMS.

COLOURED PHOTOGRAPHS.

IX.

In our last paper we carried our investigations of the reds as far as the pure scarlet, leaving us still—scarlet lake, madder carmine, and dragon's blood to complete our list of these pigments. We will therefore start with—

Scarlet Lake.—This colour is nothing more or less than a close combination of crimson lake with pale vermillion. It is this latter colour which imparts to it its scarlet hue. As I before said, crimson lake is anything but permanent, scarlet lake is even less so. Being so defective as regards its permanence, it should naturally be but sparingly used.

Madder Carmine.—This beautiful colour is a lake, which is prepared by precipitating the colouring matter extracted from the madder root in combination with alumina. As in the case of the carmine of the cochineal family, so with the carmine of the madder; it is the strongest and most powerful of a series of lakes. If we compare madder carmine with the cochineal carmine to determine its claims to a good reputation for permanence, the verdict will be very favourable to the former. Indeed, if judged solely by the latter, it may be considered an absolutely permanent colour. Authorities that have experimented with a view of settling this point are almost entirely of opinion that, submitted to the test of the ordinary diffused light of day, madder carmine is an absolutely permanent pigment. For all this, as I suggested, there are doubts; some having found that ex-

posure for a lengthened period to the influence of direct sunlight had caused it to fade slightly. Its value to a water-colour artist is principally for its deeper tinges. Madder carmine in its lighter or paler washes cannot compare with those of rose madder, which is noted for its delicacy and beauty of hue under these conditions.

Dragon's Blood.—I do not think this colour worthy of much consideration, as it is a dangerous one to use, since it will fade by exposure to the ordinary light of day. The genuine dragon's blood is a kind of resin to be found in the East Indies. It is of a warm and rather dull red hue, but may be considered as an altogether ineligible pigment, owing to its thorough lack of permanence. This, of course, refers to the genuine article, but there is an imitation colour now in the market which does duty for it. It is semi-permanent, and under the test of strong light fades, or, perhaps, it may be as correct to say, changes to a burnt sienna colour. To architects, however, it is a most useful colour, and I think we lose nothing if we leave its use altogether to them.

With this, I think we may safely leave the reds and pass on to the various colours which come under the denomination of orange pigments. Under this heading come cadmium orange, chrome orange, Mar's orange, and neutral orange. Of course, burnt sienna comes under this category, but we need not discuss it here, as we have given it ample consideration before.

Cadmium Orange.—This colour may be altogether considered as a very recent addition to the artist's colour box. I believe it has not been known for much more than a quarter of a century. It is a variety of sulphide of cadmium. It is a very lustrous and brilliant pigment, and has more than taken the place of the old "chrome orange" of years ago. There is nothing to wonder at in this, as, besides being considerably more permanent, it is also a much more mellow and beautiful colour. It is moderately transparent, and for gorgeous sunsets it may be considered simply invaluable.

Under the ordinary conditions as to exposure to light, cadmium orange may be looked upon as being perfectly permanent. I do not mean, however, to say that it will stand being exposed to strong sunlight for a considerable space of time and remain unchanged, for I well know that under these most trying conditions it becomes somewhat browner in hue. Damp has no evil influence over it, nor has impure atmosphere. Considered as a whole, it is one of the most valuable colours we possess, remarkable as it is both for its brilliance and permanence. As I said before, for gorgeous sunsets it is invaluable to the water-colour artist, to illuminators also cadmium orange has been a much valued acquisition.

Chrome Orange.—This colour consists of basic chromate of lead. Great power and brilliancy are the natural qualities of all the chromates of lead, and chrome orange is no exception to this rule. But these chromates of lead have their drawbacks, and very serious ones. There is always a certain harshness of colour, backed up by a considerable want of permanence. But this is not all: they possess a tendency to oxidise any delicate organic pigments with which they may come in contact. As a natural consequence of its lead base, chrome orange is liable to become considerably discoloured by exposure to an impure atmosphere. It is not a colour, happily, which is indispensable to an artist, since for most purposes it is effectually superseded by the steady and reliable cadmium orange.

Mar's Orange.—This colour consists essentially of sesquioxide of iron, artificially prepared, producing a subdued orange pigment. It is possessed of great purity and clearness of colour, and is to a very great extent transparent. For bright sunny tints its use, in pale washes, will be found most effective, and may be considered extremely permanent. It is a laid-down theory that Mar's orange is rather likely to injure the evanescent colours, as, for example, crimson lake or indigo; we would, therefore, be wise in avoiding as much as possible such combinations as might endanger the value of our works.

Neutral Orange.—This colour is simply a mixture of cadmium yellow and Venetian red. As a first wash, to soften the extreme brilliancy and harshness of the white paper, it will prove most effective and useful. We can rely upon its permanence. This combination was much used some years ago by Mr. Penley in his well-known water-colour drawings, and I believe it was owing to him that it was made into a pigment for the convenience of artists and designated neutral orange.

This, I think, will complete the list of orange pigments most in use, and bring us to the study of a long and beautiful line of colours—the yellows. In this category we will find—*aureolin*, deep cadmium yellow, pale cadmium yellow, deep chrome yellow, pale chrome yellow, lemon yellow, Kings' yellow, Naples yellow, Mar's yellow, Roman ochre, brown ochre, yellow carmine, Italian pink, yellow lake, and gallatone. Of course, raw sienna, yellow ochre, gamboge, and Indian yellow are

also to be found under this heading, but as we have met them before we will not require to consider their qualities.

Aureolin.—This pigment, although but a recent addition to the artist's colour box, has asserted itself and taken a high position. It consists of a double nitrite of cobalt and potassium. In theory, the stability of this pigment is put down as somewhat doubtful, but practice and experience have shown it to possess considerable permanence. It is a very beautiful colour, most delicate and transparent; many consider it to be, in point of hue, the purest of all our yellows. Aureolin mixes with the utmost safety with most of the colours. It has, however, been found to have an injurious influence upon indigo, thereby giving us the idea that it should be used with great caution in combination with the delicate organic pigments. Of course, its chemical composition leads us to easily understand that it may exert an oxidising or destructive action; this necessarily being a double danger should be fully considered when we are using it. In its paler washes I consider aureolin very beautiful, and will not fade to any appreciable extent when subjected to lengthened exposure to bright light—even sunlight. If only exposed to ordinary daylight, I feel almost sure it is as permanent as any colour we possess.

Deep Cadmium Yellow.—This pigment is a lustrous, warm, orange yellow; it is not very transparent, yet is marvellously clear and bright. I believe it to be the richest and most powerful yellow known. It consists of sulphide of cadmium, and is consequently unaffected by any impure atmosphere. It is quite possible that, if exposed for a considerable length of time to direct sunlight, it may become somewhat browner in hue, but in the ordinary daylight it is perfectly permanent. I think we will be safe in giving deep cadmium a foremost place among our most permanent colours.

Pale Cadmium Yellow.—Of this colour there are two varieties to be had—one being a rather full yellow, while the other is more lemon in hue. The former is on a par with deep cadmium yellow as regards permanence, while the latter will sooner or later fade almost completely away under the influence of ordinary daylight. I should think the manufacture of this latter pigment would have much to do with its degree of stability, but in the long run it must fade.

Deep Chrome Yellow.—This pigment is formed of a chromate of lead, to a greater or less degree basic, prepared by precipitation. It is a very brilliant yellow, but possessing, as do all the chromes, a peculiarly harsh and disagreeable quality of colour. It dulls considerably after exposure to sunlight, and in an impure atmosphere becomes black. We must be very careful as to the other pigments with which we mix this deep chrome yellow, or else the results may be most destructive. The mixture of chrome yellow with some of the blues is notoriously destructive, as, for example, Antwerp blue, Prussian, and indigo. It has a tendency as well to oxidise other substances, and great care should be taken not to mix chrome yellow with any organic pigment.

Pale Chrome Yellow.—This colour consists of neutral chromate of lead. In its various properties it is altogether similar to the deep chrome yellow. It is still less permanent, and exposure to ordinary daylight will turn it to a greenish hue. It is more usually used in combination with the various blues than the deep chrome, and necessarily our remarks about the latter apply with redoubled force.

Lemon Yellow.—There are two "lemon yellows" in the market. The genuine and permanent one is a peculiar preparation of chromate of barium. It is a beautiful semi-opaque lemon, inclining somewhat to primrose, and possessed of great purity and clearness of colour, although anything but remarkable for its intensity. The second preparation known under this name is far richer in colour, and consists of chromate of strontium. It is a very beautiful pigment, but not at all suitable for a water colour, being but slightly soluble in water—a more or less fatal drawback to a chromate. As a natural consequence it rapidly becomes green, and really should not be used under any pretext. The genuine (that prepared from chromate of barium) washes, and works easily and pleasantly. Even this, if badly prepared, will turn greenish in the course of time. I believe Field's process for producing this yellow is considered to be the best.

Kings' Yellow.—This colour is sometimes known as *Orpiment*, and is an artificially prepared sesquisulphide of arsenic. It is a bright yellow pigment, ranging about midway between aureolin and lemon yellow in hue, but is possessed of so many bad qualities that very few artists, if any, use it to-day. It soon bleaches by exposure to daylight, and is a deadly poison—a matter for consideration for those who put their brushes unduly to their mouths.

Naples Yellow.—This pigment, in the old days, used to be a compound of the oxides of lead and antimony, but is nowadays a compound product, being prepared from cadmium yellow and Chinese white. This pigment very closely resembles the original in colour,

but possesses the great advantage of being perfectly durable. It is of a pleasing pale, somewhat warm straw colour, and is opaque.

Mar's Yellow.—This pigment, like Mar's orange, is an artificial preparation of oxide of iron. It may be said to resemble the yellow varieties of ochre, but is much more transparent as well as being purer, richer, and brighter in colour. It is perfectly safe as to durability, but there are doubts as to its effects when mixed with any of the more delicate organic colours. We should think well, therefore, before we use it in any such combination. There are many who paint away and never give these matters the least consideration, and others, later on, wonder what is the matter with their pictures when they see the inevitable change working. REDMOND BARRETT.

HINTS ON THE MANAGEMENT OF THE LANTERN.

[Extract from Communication to the Birkenhead Photographic Association.]

Let us suppose that a biunial or double lantern of the ordinary construction, with the blow-through form of jet, is to be used. We may also assume that a cylinder of oxygen gas with regulator has been provided, and that we have sufficient tubing to convey a supply of hydrogen from a convenient gas bracket.

Having placed the lantern on a suitable stand, as nearly on a level with the centre of the screen as possible, with condensers and objectives carefully cleaned and in position, and the jets arranged on their supports in the lantern and properly connected with the various outlets of the dissolver, proceed to attach the hydrogen tubing to its corresponding nozzle on the dissolver, turn on the gas, and light both jets to a flame of about an inch in length. Now take your limes from the case in which they are kept and place them on the pin provided for the purpose in front of the flame. Close the door of the lantern to keep in the heat, and in a short time the limes will be thoroughly hot and all moisture will be driven from the inside of the lantern and lenses. In the meantime, adjust the oxygen regulator to the cylinder (having fixed the latter in an upright position), and connect the regulator with the oxygen nozzle of the dissolver by a sufficient length of good rubber tubing. Gently turn on the tap at the cylinder until the bag or bellows of regulator is filled, and then turn off the oxygen again. Open the oxygen tap of one of the jets to empty the regulator. If no explosion follows, you may conclude that the gas in the cylinder is not an explosive mixture and may be used with safety. Now turn on the oxygen again, opening the valve gently as before. If turned on quickly the sudden rush of gas from the cylinder will probably burst the regulator and do other injury. Proceed to light up each lantern in turn to centre and adjust the position of the light. This is done as follows:—Move the lighted jet up and down on its supporting rod and to one side or the other, as may be found necessary, until a flare of light appears in the centre of the disc on the screen. Clamp the jet in this position and slide the tray upon which it is fixed forward until the flare opens out to a clear and evenly illuminated disc. Now focus the lens by means of a picture placed in the stage of the lantern. Having done this for each lantern, light both up simultaneously and cause the two discs to coincide on the screen by means of the adjusting screws provided for the purpose in the lantern fronts. See that the by-taps on the dissolver are so regulated that when the gas is shut off from either lantern by the dissolver a small flame of hydrogen is kept burning and just tinged by a slight supply of oxygen.

On arriving at this stage you are now ready to perform your part of the evening's performance as lantern operator, and what will be most wanted on your part during the remainder of the evening is an unlimited supply of coolness and presence of mind, with a general watchfulness over the whole apparatus.

P. H. PHILLIPS.

REPORT ON THE PHOTOGRAPHIC CONVENTION OF GREAT BRITAIN, ST. JAMES'S HALL, LONDON.

August 19th to 24th, 1889.

BY THE DELEGATES OF THE PHOTOGRAPHIC CLUB—ADOLPHE M. LEVY, JOHN NESBIT.

GENTLEMEN,—The opening ceremony took place on August 19th, when a fairly large gathering assembled to hear the President's address, and also to inspect the collection of pictures and apparatus exhibited. We think it is only fair to say something in praise of those gentlemen who superintended the arrangement of the exhibits. Though the time at their disposal was extremely short, everything was put in order in due time, and it is highly creditable to state that the Exhibition was opened punctually without the usual accompaniment of packing cases and litter which generally attend such ceremonies. Among those to whom credit is due, are several members of our Club.

The presidential address consisted of a very complete and exhaustive history of photography from the time of Daguerre up to the present day. Mr. A. Pringle's authority on photographic matters is sufficient guarantee for the soundness of his discourse; this has, besides, been published in the technical papers, and will, we are sure, be read with much interest by all.

At the close of the address the members present examined the exhibits, which were fairly numerous and representative. We must state, however, that in the Apparatus Department there did not appear to be any novelty. However, a detective camera, designed by the Platinotype Company and exhibited by Messrs. Noakes, attracted a great deal of attention, one of the main features being the special method of changing plates. We think, however, that this instrument, which appears to have many commendable qualities, would be rendered more serviceable by the introduction of finders, ensuring the proper centring of the subject on the plate.

One of our members, Mr. Getz, showed a new form of tripod, which, to our mind, is most certainly in advance, so far as handiness and steadiness are concerned, of anything that has been so far put on the market.

Some objects of historical interest, consisting of very fine Daguerreotypes and negatives on waxed paper, taken by the respective authors of those processes, were exhibited by Mr. Friese Greene. Other members also showed old-form cameras, and, in particular, one of the pantoscopic type, provided with a "water lens."

During the sittings of the Convention a number of papers were read, or taken as read. These papers constitute, of course, by far the more important part of the business transacted, and we propose to devote some time to summarising them, as also the discussions to which they gave rise.

The Convention of 1889 did not bring forth the announcement of any new discovery in the realm of photographic processes. The papers brought forward were, however, very interesting, and speak highly for the amount of thought and experimentation which have been brought to bear on the subject.

The number of investigators who are devoting their time to the development and improvement of photography is daily increasing, and there cannot be any doubt that all this research will lead to considerable progress. We think, however, that there is cause for regret that so little is done towards elucidating the principles upon which photography, as a science, is based. It must be clear to all that an accurate knowledge of the true reactions undergone by the silver haloids, when subjected to the influence of light, would be an invaluable guide to all those who are endeavouring to perfect the processes now in use, or to devise new ones.

It is, however, satisfactory to find that some attention is being given to the instrumental means used in photography. We allude here to the lens question, on which the papers read by Messrs. Traill Taylor and T. R. Dallmeyer afford valuable information. Mr. Traill Taylor concerns himself mainly with the lenses to be used in hand cameras of the so-called "detective" form.

Besides describing various forms of lenses which may be utilised in this class of camera, Mr. Taylor points out the great advantages which may be derived from the use of a portrait combination. Many street views and scenes of every-day life, which cannot be obtained with an aperture of $f/8$ through lack of light, in narrow courts and alleys, can be secured with a lens working at $f/4$. Mr. Taylor says that he has obtained entirely satisfactory results with a portrait lens, but he, unfortunately, does not mention whether the instrument is of the usual type, or one of the new portrait combinations constructed on the symmetrical principle. Mr. Taylor informed his audience that very good results had been obtained with hand cameras by the use of a single lens of the meniscus form, the exposures being, however, much prolonged.

Some discussion took place with reference to the most favourable length of focus for detective work, and the balance of opinion was in favour of relatively long-focus lenses.

In our opinion, the use of portrait lenses in hand cameras would necessitate some modification in the general construction of the camera. Large apertures are accompanied by considerably less depth of focus, and a great deal more precision in focussing is consequently indispensable. It does not seem possible to set the focus by judgment with a portrait lens, the slightest deviation rendering the picture useless, through insufficient sharpness. It would, therefore, be advisable to introduce a modification by means of which the picture could be sharply focussed before exposure.

The large diameter of the lenses increases the difficulty in obtaining a suitable shutter, and this point also will require attention.

Mr. T. R. Dallmeyer's paper is entitled, *False rendering of Photographic Images by the Misapplication of Lenses*. This paper dealt mainly with the false perspective induced both in portraiture and in landscape work by the use of lenses of too short a focus. It also dwelled on the most suitable angle of view to be included in the plate.

A very important point was touched upon. In a well-known book recently published the author recommends that in a landscape the principal object itself should be slightly thrown out of focus, in order to secure a better artistic effect.

Mr. Dallmeyer points out, that whereas putting a lens out of focus tends to the destruction of structure, a softening of the picture may be obtained by the introduction of a small amount of spherical aberration. At the same time, a perfectly sharp picture is not always deficient in softness, a great deal being dependent on lighting and atmospheric conditions.

It is almost to be regretted that Mr. Dallmeyer did not develop further his remarks with reference to wide-angle lenses. The abuse of these has led to the production of many pictures which are painfully distorted in

perspective. There is no doubt that many interiors, for example, are so arranged that none but the very shortest focus wide-angle lenses can deal with them. It is a question whether, at an artistic point of view, as well as for the good name of photography, such pictures, however interesting, had not better be left alone.

In the discussion on this paper most of the speakers agreed with Mr. Dallmeyer. There appeared, however, to be some misunderstanding between him and Mr. Beck, when the latter pointed out that in taking large direct heads, the subject and the plate being at equal distances from the optical centre of the lens, a short-focus and a long-focus lens would have the same depth of focus practically. Mr. Dallmeyer replied that with a long-focus lens the result would be better. Mr. Beck had never doubted that the result would be due, not to increased depth of focus, but to better perspective.

A paper by Mr. Dunmore was taken as read, the author not being present. This is to be regretted, as the subject—i.e., *The Determination of the Relative Rapidity of Gelatine Plates*—is a much vexed question, and some valuable discussion might have been elicited. We think that Mr. Dunmore's paper might be advantageously discussed at one of the meetings of our Club.

Mr. A. Haddon read a paper on *Desensitising and Resensitising Albumenised Paper*. The experiments recorded by the author are extremely interesting, inasmuch that they show that albumenised paper which has been once sensitised cannot be entirely deprived of its sensitiveness, at least by any of the reagents he has tried. The discussion on this paper did not bring forth any new facts, and several speakers seemed to agree with the author that the title of his paper was not happily chosen.

The audience did not seem to grasp the object of the investigation carried out by Mr. Haddon, and the discussion strayed in consequence from the paper itself to a general discussion on the effects of various treatments of sensitised paper in its printing qualities. The principal fact elucidated by this paper seems to be that a certain proportion of free nitrate of silver is requisite to obtain first-class results.

A very important discussion took place on the "Report of the Committee upon Lens Standards" being read. This report was deemed inefficient, and was referred back to the Committee. Some gross errors were pointed out, and several speakers commented severely on the way in which the Committee had performed its mission.

The advisability of having a series of standard flanges to be used by all opticians was warmly approved of, but at the same time it was pointed out that whatever system was to be arrived at, the co-operation of the principal lens makers would be essential to success.

With reference to stops, general satisfaction appeared to be given by the system actually in use. A member, however, thought that the subdivisions of focal length had better have for unit a decimal number. Efforts were being made in many directions to secure the adoption of the decimal system, and if a change was to be made in lens fittings, it might be as well to make the parts on that system.

It was resolved to appoint a Committee, in which should be included the principal opticians. This Committee would endeavour to arrive at a solution of the question, equally satisfactory to the interests of the opticians and to that of the photographic public.

Professor Bothamley read an exhaustive paper on *Orthochromatic Photography on Gelatine Plates*. This paper may be taken as an embodiment of all that has been done up to date with reference to the tone-rendering of values by photographic negatives. The only process not mentioned is the chlorophyll method, originated by Ives, and with which the author does not appear to have experimented.

The very great bearing which the development of orthochromatic processes must have on the future of photography enhances very materially the importance of Mr. Bothamley's investigation, and we think it advisable to sum up here the conclusions to which he has arrived.

Three points, says the author, require quantitative investigation, viz:—

The necessity for, or advantage of, a preliminary bath of alkali.

The influence of alcohol in the sensitising bath.

The necessity for, or advantage of, washing after treatment with the dye.

These three operations have been held to be essential by some authors.

Mr. Bothamley investigates the action of each treatment by the effect it has on the sensitiveness of the plate, measured by a sensitometer under well-determined conditions of illumination and development.

The conclusions drawn from the sensitometer numbers obtained are as follows:—

The preliminary bath of alkali may be omitted.

Alcohol up to ten per cent. has no influence, and may be dispensed with when the dye is soluble in water. In larger proportions it produces a decrease in sensitiveness.

With a concentration of the dye up to 1 : 5000, the after washing of the plate is quite unnecessary.

Mr. Bothamley states that density is more easily obtained with orthochromatic than with ordinary plates, and recommends a developer containing much less pyro than usual. The examples of orthochromatic photography exhibited side by side with photographs of the same subjects on ordinary plates were certainly not very conclusive as a rule, the difference shown not being as great as might have been expected. Some of the pictures on ordinary plates would have most certainly been better had a weaker developer been used, or local development resorted to. In commenting on the results he has obtained, Mr. Bothamley remarks that

insufficient exposure with ordinary plates is often the cause of inferior results with reference to values. This is a hint which is of some importance in these days of so-called instantaneous shutters. The next point of importance treated by Mr. Bothamley is the use of the yellow screen. It has been claimed by makers of isochromatic plates that this adjunct could be dispensed with. Mr. Bothamley shows, however, that the gain obtained over ordinary plates is but slight, and that to arrive at really good results a yellow screen of greater or lesser colour intensity, as the case may be, is indispensable. The selection of a screen of proper colour, suitable to the subject to be photographed, constitutes the main difficulty of orthochromatic photography. Too great depth of tint gives as bad results, with reference to values, as ordinary plates. This is very probably the reason why so many pictures taken on isochromatic plates fail to show any appreciable advantage over ordinary plates. No rule can be given for the choice of coloured screen. This, like the length of exposure and many other data in photography, can only be arrived at by prolonged experience.

It is interesting to notice the figures given by Mr. Bothamley with reference to the action of dye solutions on various makes of plates. There is a considerable difference as to sensitiveness, some makes being much more affected than others.

Rhodamine gives a considerable decrease in the sensitometer number, as compared with erythrosine. All this seems to show that orthochromatic methods are still very imperfect, and that a great deal remains to be done before they arrive at that stage of development, when they will undoubtedly replace entirely the commercial gelatine bromide plate.

Three papers were taken as read:—

Past and Present, by W. M. Ashman.

For Talbot—His Early Experiments, by Friese Greene.

Photo-mechanical Printing Methods, by T. Bolas.

The two first papers are purely of historical interest. Mr. Bolas's paper is very exhaustive, and will, without doubt, be read with much interest by those who work at engraving processes in conjunction with photography.

Every evening lantern-slide exhibitions were given, and slides of great beauty were shown. Pre-eminent among these displays was Mr. E. Muybridge's lecture on animal locomotion, profusely illustrated by the optical lantern, and also by an instrument specially constructed for the purpose, and called the zoopraxiscope.

Mr. Muybridge's researches throw much light on the subject of animal locomotion, and show how little has hitherto been known about this subject. The works of some of the most esteemed painters are proved to be faulty in this respect, and it is much to the credit of photography to have been the means of rectifying grievous errors in the delineation of animals in motion.

Some slides were exhibited showing the apparatus used. Forty-eight cameras were set up in series of twenty-four and two twelves, so that simultaneous views were obtained of the same subject from three points of view. The most interesting part of the appliances is the arrangement which effects the exposure. The apparatus is electro-magnetic, and so designed that variable speeds of rotation can be given to it. As the drum revolves, it releases consecutively the shutters of the lenses, and it will be readily understood that if the speed of the drum is proportional to the rate of motion of the animal under experimentation, it will be possible to take a series of pictures representing the various phases of one and the same stride, as the animal passes along the course in front of the main battery of twenty-four cameras. The electric current can, of course, be applied at the most suitable moment, at will.

A series of lantern slides obtained from the negatives of consecutive phases being placed in the zoopraxiscope and thrown on the screen, the animal is seen in movement in a most realistic manner.

It is to be hoped that Mr. Muybridge will, if he has not already done so, embody in a book the result of his observations. His experiments were all made with portrait combinations, and this brings us back to the statements made in Mr. Traill Taylor's paper with reference to the use of lenses of this class for instantaneous work. A feature of Mr. Muybridge's apparatus is that the shutters are on a stand entirely independent from the cameras themselves, thus avoiding any chance of vibration being communicated to the apparatus. These shutters are of the drop type, and in this case a considerable height of fall is provided before the aperture actually passes in front of the lens.

The results obtained by Mr. Muybridge, will, no doubt, encourage other experimenters to devote some attention to this branch of photography. The difficulties are certainly very great, and the apparatus requisite very considerable and consequently expensive.

We regret not to be able to give any account of the various excursions, which, we believe, were very successful. A dinner and smoking concert took place on the 23rd. This was well attended, but we must refer you to those who were present, as we could not attend ourselves. We will conclude this report by an account of what passed at the General Meeting held at the Society of Arts on August 21, and at the Council Meeting on August 24.

Mr. Andrew Pringle, President, in the chair. The attendance was thin, the weather being most unfavourable. After reading and signing the minutes of the previous meetings, the first matter on the agenda was discussed. This was the selection of a locality for next year's meeting. An informal invitation having been received last year from Chester, it

was agreed that the meeting be held next year in that town. The co-operation of the Liverpool and Manchester Photographic Societies was to be obtained. Chester has many advantages, there being a great deal of subjects for photography.

The members of the General Committee were then elected. Some discussion took place with reference to the advisability of augmenting the subscription of members of the Convention. It was proposed that in future the subscription should be 10s. instead of 5s., but many speakers appeared to think this increase disadvantageous, so it was finally decided that the subscription should remain fixed at 5s.

At the same time, those who contemplated joining the Convention next year were requested to send in their subscription at once, so that the Secretary should be able to have something on which to base his estimates. It was also decided that the date of this year's meeting being most unfavourable, future Conventions should be held at an earlier date, either at the end of June or the beginning of July.

PHOTOGRAPHY AT THE PARIS EXHIBITION.

If by placing the Exhibition of Photographic Negatives and Apparatus on the first floor of the "Palac' des Arts Liberaux" it was intended to screen those exhibits from contact with the crowd—which certainly sometimes is the reverse of considerate—the attempt has proved a signal success. We have satisfied ourselves, much to our regret, that the public is very shy of climbing up the stairs which lead to Class XII., although there is a constant crush in the ground-floor galleries running all around the building.

This want of visitors is all the more unaccountable when it is remembered that almost every one, nowadays, "goes in" for photography, and consequently takes an interest in every detail relating thereto. In all probability, many among the millions of people that have come to see the Exhibition went home greatly disappointed at not having been able to find the department of photography. And yet there are a great many pretty things to be seen in that succession of gorgeously got-up salons, where the most celebrated photographers of Paris and other large cities have very tastefully displayed the finest specimens of their work, the results of constant labour and of uninterrupted endeavours to approach perfection.

The times are past when hirsute photographers used to afford ready food for the satire of Gavarni, De Daumier, and Cham. That species of photographer has long since departed from our midst, along with Musset's and Murger's students and *grisettes*. The present photographer is not unfrequently an accomplished scientist; he must be in every instance skilled in chemistry. Acetates, acids, bromides, chlorides, iodides, nitrates, and sulphates, are things he has to manipulate constantly. He makes new discoveries every day, invents improved methods, and thus gradually gets the start of his fellow-workers, until he is in his turn superseded.

Photography is an art that cannot remain stationary; those who practise it have no right ever to say to themselves, "Let us stop here, we need go no further." The Jury of Rewards must have been rather at a loss when they had to classify the exhibiting photographers. There are about a dozen rival firms who seem to have achieved an equal degree of success. Which of those portraits, so astonishingly lifelike, or of those landscapes, so neat and so minute in detail, are, in preference to the others, entitled to the prize? M. Carnot's portraits are of course numerous, so are also the likenesses of other French public characters. The exhibitors were evidently anxious to behave with civility.

As photography was becoming more and more popular, it became necessary to facilitate the exercise of it. The idea of carrying about heavy apparatus for hours together was likely to discourage many amateurs; besides, the position of a man erecting his "travelling stand" and camera in the middle of some road or village is generally not quite free from ridicule.

Instantaneous processes, doing away with the necessity of long focussing, have enabled small hand apparatus to be constructed, which hold no more space in one's pocket than a note-book, and are ready to work at any moment, owing to the fixed focus of the objective. These portable apparatus have now been brought to a degree of perfection which enables instantaneous photographs to be taken while travelling by express train. And last, not least, they offer facilities for perfidiously photographing people in spite of themselves.

Very interesting negatives have also been obtained by instantaneous methods, showing the successive phases of movements. Thus, a detachment of soldiers may be seen marching at quick time: it has been taken in one-fiftieth of a second, and the negative shows every man of the company with one leg up. In the same way the various attitudes of children playing at leap-frog and other outdoor games are grasped in an instant.

M. Albert Londe, Director of the Photographic Department of Dr. Charcot's clinique at the Salpêtrière, exhibits a whole series of negatives showing the effects of faradisation upon the muscles of the patients' faces, while they are in a state of catalepsy. This is an interesting collection to examine, which testifies to the immense services photography is called upon to render to science.

The scientific application of this art is, in fact, extending in many more directions. Astronomers, balloonists, &c., are thereby enabled to record

data which hitherto had remained unnoticeable, and to reproduce instantaneous phenomena of which not even a trace could be discovered before. Geography and topography, again, are in a great measure benefited by the improvements made in the art of photography.

The results that have been obtained for the last few years by searching and enterprising photographers are very important. Photographs can now be taken indistinctly upon paper, glass, wood, cloth, and enamel. In this connexion one of the exhibitors showed us direct photographs upon wood and upon leather, without any film, being applicable in the cabinet-making, upholstering, and bookbinding industries, as well as for a great many other purposes.

Photochromy, too, has made considerable progress; however, in this respect the way is still open to inventors. It is not credible in effect that, considering the infinite resources placed at the disposal of photographers by electricity, they should fail before long to obtain images in the natural colours and shades of the objects reproduced. Painters will most likely be rather disgusted when that time comes, and will talk a good deal about the profanation of fine art!

Photography is not over half a century old, and yet is not the progress wonderful that has been made since the times of Daguerrotype? It has, no doubt, more pleasant surprises in store for us, especially if it should be taken in hand by a gentleman of the Edison type.

—*Petit Journal*, Paris, September 18, 1889.

OPINIONS OF THE LONDON DAILY PRESS ON THE PHOTOGRAPHIC EXHIBITION.

[*The Times*.]

THE season of winter exhibitions is already upon us, and first in the series comes that of the Photographic Society of Great Britain, the private view of which was held on Saturday, in their rooms in Pall-mall East. It is almost superfluous to say that every form of photographic art, whether as regards subject or process, is adequately represented, with the exception possibly of objects in rapid motion, such as express trains, and limbs of human beings, or animals in active exercise. A very cursory inspection of the pictures enables the visitor to realise the immense strides which photography has taken during the last quarter of a century; how great have been the contributions of chemistry, how much skill and artistic feeling in the composition of the pictures and the treatment of subjects have been brought to bear upon the application of what at one time appeared to be a merely mechanical process. Even the element of colour, the absence of which is usually held to be a primary defect in photography, is to some extent, and especially by the later processes, brought into play. One of the first things which strikes one is the great superiority as regards the tone and softness, distance, and light and shade of the application of the bromide, platinotype, carbon, and other recent processes over the earlier silver methods. The modern prepared papers, such as the Pizzighelli, bromide, Obernetter, chloride, Blanchard's paper, and others, also contribute largely to the excellence of the specimens shown on these walls. In many cases effects are produced very similar to those of the old mezzotints. Especially successful are the different applications of platinum, "hot," "cold," and "warm," of which examples are frequent in this Exhibition. Of course the great majority of the pictures are by the hands of our fellow-countrymen, or are the work of British Companies or Associations, such as the Autotype Company, which is fertile both in excellence and in numbers, the Sciopicon Company, whose exhibits possess exceptional value, and the Typo-Engraving Company; but there are also many foreign examples, especially American and German. It is very satisfactory to be able to say that British photography distinctly carries off the palm. Excellent as undoubtedly many of the German works are, there are to be noted in them a greater hardness and less delicacy in the matter of distance and outline than in their English rivals. In estimating the quality of a really artistic photograph, it is, of course, difficult to analyse how much of the product is due to the original mechanical operation, and how much to "composition" and manipulation subsequent to the original action of light and the other physical agencies. But, just as the painter must "mix his paints with brains," as was said on a memorable occasion, so in every kind of photograph, even in the simplest portraiture, there is ample scope for brains, for delicacy of perception, and for nice artistic touch. There is, in truth, an idealism possible in photography as in painting; and, as these walls testify, it is not beyond its range adequately to present to view, not only the outward lineaments, but the inner man with his thoughts, emotions, and desires. Nor can a complete conception be attained of the dignity of the photographic art without realising the immense contributions which it has levied and is levying on the science of chemistry. Celluloid films, the subtle composition of carbon, chloride, and bromide papers, the use of platinum at different temperatures, the marvellous sensitiveness of gelatine, the revelations of the microscope, and the infinite operations which are employed to give permanence to evanescent products, furnish ample evidence of the countless demands which photography makes upon the highest activities of the human brain.

Turning to the pictures themselves, one finds that the greatest success has been achieved precisely where success might be thought most difficult—viz., in landscape and subject pictures. One remarks especially how

admirably snow always comes out—though this is due, perhaps, as much to the character of the object as to the skill of the artist. A more difficult feat is the representation of yachting. The yachting pictures are uniformly excellent. The chief contributors in this department are Messrs. G. West & Son, who devote themselves almost exclusively to this class of subjects. Mr. Harry Symonds also contributes excellent "Yachting Scenes." What many will be disposed to consider the most charming object in the Gallery is a picture by Mr. H. P. Robinson, marked "Not for competition," *Merry Fisher Maidens*, a scene on the beach, if we mistake not, at Hastings—beautiful in composition, colour, and softness of outline. Good illustrations of the different methods of platinotype are afforded by Mr. George Davison's four pictures, *Albury Heath* (hot), *Oster Gathersers* and *Low Water at Wickenhoe* (sepias), and a *Breezy Corner* (warm). An excellent snow effect is realised in Mr. Truman Wood's *Mont Blanc from the Summit of Mont Buet* (Eastman stripping film), and in Mr. G. Renwick's *Frost Studies*. Mr. J. Gale contributes very satisfactory specimens in platinotype—*Village News*, and *The Monks' Walk at Chenies*, and two others. Mr. Lyddell Sawyer sends a beautiful riverside scene, *Dangerous Company*, which has been awarded a medal. It is the old story of a man with a maid—a rural scene, with boat, and river, and trees, and human forms, represented with great delicacy and truth. Messrs. Werner & Son have a fine portrait of *The Last of the Desmonds*, an old man with long white beard and picturesque cloak. Mr. B. Gay Wilkinson, jun., gains a medal for capital platinotypes, *Shrimping and Praising*, and contributes other meritorious works. In representations of buildings, Herr Anselm Schmitz has been awarded a medal for large and striking pictures of Cologne Cathedral, and of a staircase in the Royal Castle of Brühl, Cologne; and Mr. W. J. Stillman gives excellent autotype enlargements of the Temple of Concord at Girgenti, and the interior of a temple at Segesta, Sicily—admirable illustrations of the extreme truthfulness of photography. Mr. Frank M. Sutcliffe sends a considerable number of works of high merit, mostly on Blanchard's platinum paper. In respect of three of them, *Saturday Afternoon*, *Fish Stall*, and *Dinner-time*, he has received the medal of the Society. A beautiful scene, *The Evening Hour, Whitby*, in which the water and reflections in it are shown with singular delicacy, contributed by the Autotype Society, is also taken from a negative by this artist. Mr. W. Dillworth Howard sends soft and finished views on the Italian lakes; if we are not in error, from the Lago Maggiore and Lago di Orta. Mr. Van der Weyde's *Adoration of a Doll*, an enlargement in red chalk in three panels, is more conspicuous than pleasing, and the colouring is decidedly too pronounced. Messrs. Green Brothers have well earned their medal for their lake scenes—*Buttermere*, *Thirlmere*, *Head of Derwentwater*, and *Langdale Pikes*—which are all executed on bromide paper. Colonel W. L. Noverre's *Penance Harbour*, on specially prepared rough drawing paper, is also worthy of notice. Mr. S. Bourne exhibits a series of admirably finished country scenes, on Pizzighelli paper, from Cromer, Nottinghamshire, and North Wales. Mr. D. H. Macfarlane also sends good work of Norwegian and Highland scenes; and Mr. W. J. Byrne sends two excellent genre photographs: *The Town Artist—Experience*, and *The Village Artist—Youth*. *Sleepy Hollow*, from a photographure from nature, by Messrs. A. & C. Dawson, contributed by the Typo-Etching Company, is one of the best rural scenes in the Exhibition, and well merits the medal which it has gained.

Ludlow Castle, by the Autotype Company, from a negative supplied by W. Bedford, is an excellent representation of foliage; and *Home Studies*, by Mr. Henry Stevens, and *Sweet Spring-time*, by Mr. Ralph W. Robinson, of domestic scenes. Of reproductions of famous pictures, that of the Autotype Company, for which a medal is awarded, an autogravure of Mr. Holman Hunt's *Early Christian Missionaries fleeing from Persecution* is especially worthy of commendation for the finish and accuracy of detail and outline. The same Company furnish admirable representations of the same artist's pictures, *A Tuscan Girl*, scenes from the *Two Gentlemen of Verona*, and *Rienzi vowing vengeance for the Death of his Brother*. The Goupilgravure of Sir P. Leighton's *Daphnephoria*, exhibited by Messrs. Bousod, Valadon, & Co., is hung rather too high to make careful inspection possible. Messrs. Bousod, Valadon, & Co. also send an admirable Goupilgravure printed in colours from a single plate, which makes one desire to see other specimens of similar coloured work, and an exceedingly charming river scene entitled *L'Appel au Passer*. Two pictures by Mrs. Edward Penton well merit attention for two reasons. They are called *A Cornish Fisherman* and *A Newlyn Fishwife*. The first reason is the excellence of the works themselves in composition and colour, and the other refers to a matter too little heeded by artists. The frames are made of broad pieces of plain wood, which harmonise admirably with the tone of the works themselves, and afford a pleasing contrast to the usual vast area of white mounting and ugly or uninteresting frames, which are apt to detract so much from the effect of most of the pictures.

Of the portraits, the highest standard is unquestionably reached by Mr. Fred. Hollyer, who has been equally fortunate in the choice of artists and of subjects. The subjects are Mr. Watt's portraits of Cardinal Manning and Mr. Matthew Arnold, and the same artist's pictures, *The Happy Warrior* and *Good Luck to your Fishing*, and Mr. Rossetti's *Beata Beatrix*. The idealistic and spiritual character of these paintings are reproduced in the photographs to an extent which one would

scarcely have believed to be attainable. Mr. Robert Faulkner gains a medal for his striking portrait of Professor Stuart Blackie. Mr. Ralph W. Robinson also receives a medal for an excellent series of photographs of Royal Academicians and Associates, mostly in their working attire, of which the most remarkable are those of Mr. Watts, Mr. Storey, and Mr. Waterhouse. Mr. F. H. Evans, whose distinction lies chiefly in another field, as will shortly appear, contributes some excellent platinotype "At Home Portraits." Admirable "At Home Photographs" of the German Emperor, taken at Osborne on August 5, 1889, by Mr. W. J. Byrne, and of Prince Edward of Saxe-Weimar, by Messrs. Werner & Son, also appear. We could, however, well have spared the large and somewhat aggressive photograph by Messrs. Elliot & Son of Mrs. Alice Shaw (*La Belle Siffluse*). A special word of praise in speaking of portraits is due to the really excellent photographs of children—the most difficult of subjects—sent by Mr. K. Faulkner.

No work in the Gallery, however, deserves more attention than the admirable specimens of photo-micrography, sometimes miscalled micro-photography, exhibited by Mr. F. H. Evans. The result is achieved by means of a spot lens, and the work shows with incredible subtlety of detail the cirri of barnacles, the jaws of a spider, the parasite of a queen-bee, and other infinitesimal objects in a manner which can only be compared—and the comparison is inadequate—to the finest Venetian or Brussels point-lace. Infinite possibilities are thus opened out of usefulness on the part of photography to biological science, undreamt of in the earlier stages of the art. The specimens of the Woodbury process exhibited by the Sciopticon Company are also deserving of minute attention, by means of which the original impressions, printed in ordinary ink or in a pigment instead of by the usual chemical means, and subjected to a pressure of seventy tons, gain a permanence otherwise unattainable. The lantern transparencies, for which Mr. F. B. Combrano, jun., has a medal awarded him, are also most beautiful and interesting. A large collection of the most recent photographic apparatus is also exhibited, chiefly the work of Messrs. J. F. Shew & Co.

On Saturday evening, Mr. James Glaisher, F.R.S., the President, and the Council of the Society entertained a numerous company at a *soirée*.

[Daily News.]

THE private view of the Photographic Society's Exhibition was held on Saturday at the Old Water-Colour Society's Rooms in Pall-Mall. It will be remembered how a few years ago the favour with which dry plates were received revolutionised the art of photography and practically did away with the old wet process. The feature of the present season is an equally marked triumph of platinum over gold and silver in the finished picture. Everywhere the platinotype, as it is called, meets the eye, and the cool, grey tones, with their reposeful effect, enhance the pleasantness of the compositions, no less than their superior permanence increases the value. The general effect of the Gallery is that of a black-and-white exhibition, with no unfinished sketches. Picturesqueness and a rapid impressionist effect are obtained in many of the works, whose variety in size, from the statuesque to the microscopic, enables the hangers to dress the walls effectively, and does away with the depressing monotony of minuteness, which is the bane of an ordinary collection of photographs. The first-class exhibits keep their place, but marked improvement will be noticed amongst those of secondary importance. The ranks are closing up. Among the portraits, what is most striking is the frequent evidence of technical difficulties surmounted. The mere extension of size is not the chief of these. Naturalness, and a look of daily life and ease have been signally obtained in the series of Academicians at the foot of the room—Peter Graham, Marks, and MacWitter, the best—by Mr. Robinson, of Leamington, whilst Mr. W. J. Byrne's fifteen portraits of ladies in Court dress are remarkable, not only for the faithful rendering of pleasant high-bred English faces, but for the skilful differentiation of the delicate contrasts offered by the tones and surfaces of white arms, white dresses, white leathers, white flowers, and white veils. The landscapes, however, predominate. In many the artist's happiness in choice of subject and selection of the right moment has enabled photography to vie with composition. Mr. Lyd Sawyer's series (No. 53, &c.) of river subjects supply admirable illustration of this peculiar excellence. No. 54 would delight Mr. Wyllie and the admirers of his work. The views of Grasmere (Nos. 178 and 179, from the camera of Mr. J. A. Green, a medallist, by the way) are remarkable for the combination of broad aerial effects in mountainous backgrounds and crisp emphasis of reeds and branches nearer the eye. Close by are three masterly sea pieces (No. 180) on a rough, grained, water-colour paper, which gives them the effect of uniting the free touch of water colour to the truth of science. Above these a triptych at the head of the room shows once for all that children may be represented in photography fully the size of life without any appearance of heaviness or exaggeration. The sensational element is not omitted; on the contrary, it has been caught on the wing. The series in frames No. 319-320, representing a balloon filling, rising, floating away, and then discharging its parachutist into space, are records of an exciting moment and thoroughly up to date. But some of the most agreeable impressions are left by the simplest subjects—by such little bits of pure landscape as Nos. 285 and 286—the first, the edge of a pool with a clump of rushes in the front and a streak of broad light over the water, and the weedage skirting the clumps of trees, all under a grey sky; or No. 598, a

marvellous little group of Italian peasant children brimming over with fun and laughter, in the strong Southern sunshine.

[Daily Telegraph.]

THE steady advance of the photographic art—for art indeed it has come to be—is shown by the excellent collection of high-class work now on view at the Galleries at 5A, Pall-Mall East. Year after year we have had occasion to note the progress made under the auspices of the Photographic Society of Great Britain, and the 600 photographs now on view can honestly be said to "beat the record." There is continued evidence of the desire to make real pictures, and not mere mechanical records of fact; and the laws of composition, the nice sense of relative balance of tone-values, as artists put it—and, what is perhaps of chiefest import, a strong dramatic feeling—are shown in the best things of this fascinating collection. Among the novelties there are some delicate opaline portraits by Mr. Friese Greene, who has carried this subtle process to perfection, and whose mounting is thoroughly artistic and wonderfully clear work on the new celluloid material; every line as firm as if cut by Albert Dürer himself, and, as a contrast, soft, impressionist work caught through a pin-hole, without the intervention of a lens; and such studies of racing yachts and moving life as are sent by Messrs. G. West. Mr. Friese Greene's opal photographs carry the work of invention in reducing the time of taking a picture a step further; they dispense with the necessity of toning, and thus a photograph can be completed in less than an hour. The series of artistic "Celebrities at Home" contributed by Mr. R. W. Robinson, are of chief importance among the portraits, and in this line Mr. Abel Jervis, Mr. Robert Faulkner, and Messrs. Byrne, hold high places. Mr. Fred Hollyer is the authorised interpreter of the works of Watts and Rossetti, and his studies are faithful and sympathetic. Mr. Van der Weyde contributes the chief work, a humorous triptych, called the *Adoration of a Doll*, an enlargement in red chalk, with a quaint parody of medievalism about it that is pleasant and innocent. Mr. S. Bourne's glimpses at country life, Mr. Davison's series in Essex, and Mr. Frank Sutcliffe's studies of fisher-folk are all of high merit, and a word must be said for the good work shown by lady photographers, amongst whom Miss Florence Harvey takes high rank. Photographs are not exactly things that demand detailed criticism, and when reference has been made to the happy choice of a subject in which the artistic element shows itself, and the beauty of the result in which the workman-like element comes out, there is no more to be said. These qualities are certainly shown in successful combination on these walls, and here comes in the practical lesson to be taken in earnest by the growing army of amateur photographers who trot about the world with their "detective cameras," snatching at a smile or a sunset as suits their caprice. To buy a portable camera, to "shoot" an effect, then to send your negative to one man to develop, to another to print, to a third to mount and frame, and then to call the result "my photograph," is but a foolish child's game. The true photographer is in his own way as "thorough" as the conscientious etcher, and completes every process himself. This is the lesson that the amiable amateur should take to heart as he makes an affectionate study of these masterpieces of scene pictures. The Society held their annual *coursaazione* on Saturday evening when the President, Mr. James Glaisher, F.R.S., and the Hon. Secretary, Captain A. M. Mantell, received a goodly company of those interested in the attractive art.

BRITISH ASSOCIATION.*

SECTION A.—(MATHEMATICS AND PHYSICS.)

[Opening Address by Captain W. de W. Abney, C.B., R.E., F.R.S., F.R.A.S., President of the Section.]

ONE of the reproaches that in early days was cast at photography was its inability to render colour in its proper monochromatic luminosity. Thus, whilst a dark blue was rendered as white in a print—that is, gave a dense deposit in a negative—bright yellow was rendered as black in a print, or nearly so—that is, as transparent, or nearly transparent, glass in the negative. To the eye the yellow might be far more luminous than the blue, but the luminosity was in the photograph reversed. I need scarcely say that the reason of this want of truth in the photograph is due to the want of sensitiveness of the ordinarily used silver salts to the least refrangible end of the spectrum. Some fifteen years ago, Dr. H. W. Vogel announced the fact that when silver salts were stained with certain dyes they became sensitive to the colour of the spectrum which the dyes absorbed. This at once opened up possibilities, which, however, were not at once realised, owing, perhaps, to the length of exposure required when the collodion process was employed. Shortly after the gelatine process was perfected, the same dyes were applied to plates prepared by this method, which, although they contained the same silver salts as the old collodion process, yet, *per se*, were very much more sensitive. A new era then dawned for what has been termed isochromatic and orthochromatic photography. The dyes principally used are those belonging to the eosine group and cyanine—not the ordinary cyanine dye of commerce, but that discovered by Greville Williams. For a dye to be of use in this manner it may be taken as an axiom—first propounded by the speaker, it is believed—that it must be fugitive, or that it must be capable of forming a silver compound. The more stable a dye is the less effective it is. If we take as an example cyanine, we find that it absorbs in the orange and slightly in the red. If paper or collodion stained with this colouring matter be exposed to the action of the spectrum, it will be found

that the dye bleaches in exactly the same part of the spectrum as that in which it absorbs—following, indeed, the universal law I have already alluded to. If a film containing a silver salt be dyed with the same, it will be found that whilst the spectrum acts on it in the usual manner—viz., darkening it in the blue, violet, and ultra-violet—the colour is discharged where the dye absorbs, showing that in one part of the spectrum it is the silver salt which is sensitive, and that in the other it is the colouring matter. If such a plate, after exposure to the spectrum, be developed, it will be found that at both parts a deposit of silver takes place; and further, when the experiment is carefully conducted, if a plate with merely cyanine-coloured collodion be exposed to the spectrum and bleached in the orange, and after removal to the dark room another film containing a silver salt be applied and then a developer, a deposit of silver will take place where the bleaching has occurred. This points to the fact that the molecules of a fugitive dye, when altered by light, are unsatisfied, and are ready to take up an atom or atoms of silver, and other molecules of silver will deposit on such nuclei by an action which has various names in physical science, but which I do not care to mention. This is the theory which I have always advocated, viz., that the dye, by its reduction, acts as a nucleus on which a deposit of silver can take place. It met with opposition, a rival theory, which makes the dye an "optical sensitiser"—an expression which is capable of a meaning which I conceive contrary to physical laws—being run against it. The objection to what I may call the nucleus theory is less vigorous than it has been, and its diminution is due, perhaps, to the more perfect understanding of the meaning of each other by those engaged in the controversy. To my mind, the action of light on fugitive dyes is one of the most interesting in the whole realm of photography, as eventually it must teach us something as to the structure of molecules, and add to the methods by which their coarseness may be ascertained. Be the theory what it may, however, a definite result has been attained, and it is now possible to obtain a fair representation of the luminosity of colours by means of dyed films. At present the employment of coloured screens in front of the lens, or on the lens itself, is almost an essential in the method when daylight is employed, but not till some day is discovered which shall make a film equally sensitive for the same luminosity to the whole visible spectrum will it be possible to make orthochromatic photography as perfect as it can be made. The very fact that no photograph of even a black-and-white gradation will render the latter correctly must of necessity render any process imperfect, and hence in the above sentence I have used the expression "as perfect as it can be made."

The delineation of the spectrum is one of the chief scientific applications to which photography has been put. From very early days the violet and ultra-violet end of the spectrum have been favourite objects for the photographic plate. To secure the yellow and red of the spectrum was, however, till of late years, a matter of apparently insurmountable difficulty; whilst a knowledge of that part of the spectrum which lies below the red was only to be gained by its heating effect. The introduction of the gelatine process enabled the green portion of the spectrum to impress itself on the sensitive surface; whilst the addition of various dyes, as before mentioned, allowed the yellow, the orange, and a portion of the red rays to become photographic rays. Some eight years ago it was my own good fortune to make the dark infra-red rays impress themselves on a plate. This last has been too much a speciality of my own although full explanations have been given of the methods employed. By preparing a bromide of silver salt in a peculiar manner one is able so to modify the molecular arrangement of the atoms that they answer to the swings of those waves which give rise to these radiations. By employing this salt of silver in a film of collodion or gelatine the invisible part of the spectrum can be photographed and the images of bodies which are heated to less than red heat may be caused to impress themselves upon the sensitive plate. The greatest wave-length of the spectrum to which this salt is sensitive so far is 22,000 μ , or five times the length of the visible spectrum. The exposure for such a wave-length is very prolonged, but down to a wave-length of 12,000 it is comparatively short, though not so short as that required for the blue rays to impress themselves on a collodion plate. The colour of the sensitive salt is a green-blue by transmitted light; it has yet to be determined whether this colour is all due to the coarseness of the particles or to the absorption by the molecules. The fact that a film can be prepared which by transmitted light is yellow, and which may be indicative of colour due to fine particles, together with an absorption of the red and orange, points to the green colour being probably due to absorption by the molecules. We have thus in photography a means of recording phenomena in the spectrum from the ultra-violet to a very large wave-length in the infra-red—a power which physicists may some day turn to account. It would, for instance, be a research worth pursuing to photograph the heavens on a plate prepared with such a salt, and search for stars which are nearly dead or newly born, for in both cases the temperature at which they are may be such as to render them below red heat, and therefore invisible to the eye in the telescope. It would be a supplementary work to that being carried out by the brothers Henry, Common, Roberts, Gill, and others, who are busy securing photographic charts of the heavens in a manner which is beyond praise.

There is one other recent advance which has been made in scientific photography to which I may be permitted to allude, viz., that from being merely a qualitative recorder of the action of light it can now be used for quantitative measurement. I am not now alluding to photographic actinometers, such as have been brought to such a state of perfection by Roscoe; but what I allude to is the measurement and interpretation of the density of deposit in a negative. By making exposures of different lengths to a standard light, or to different known intensities of light, on the same plate on which a negative has to be taken, the photographic values of the light acting to produce the densities on the different parts of the developed image can be readily found. Indeed, by making only two different exposures to the same light, or two exposures to two different intensities of light, and applying the law of density of deposit in regard to them, a curve is readily made from which the intensities of light necessary to give the different densities of deposit in the image impressed on the same plate can be read off. The application of such scales of density to astronomical photographs, for example, cannot but be of the highest interest, and will render the records so made many times more valuable than they have hitherto been. I am informed that the United States astronomers have already

* Concluded from page 625.

adopted the use of such scales which for the last three years I have advocated, and it may be expected that we shall have results from such scaled photographs which will give us information which would before have been scarcely hoped for.

One word as to a problem which we may say is as yet only qualitatively and not quantitatively solved. I refer to the interchangeability of length of exposure for intensity of light. Put it in this way. Suppose that with a strong light, L, a short exposure, E, be given, a chemical change, C, is obtained: will the same change, C, be obtained if the time is only an *n*th of the light, L, but a times the exposure? Now this is a very important point, more particularly when the body acted upon is fairly stable, as, for instance, some of the water-colour pigments, which are known to fade in sunshine, but might not be supposed to do so in the light of an ordinary room, even with prolonged exposure. Many experiments have been made at South Kensington as regards this, more especially with the salts of silver, and it is found that, for any ordinary light, intensity and exposure are interchangeable, but that when the intensity of light is very feeble, say the one-one-millionth of ordinary daylight, the exposure has to be rather more prolonged than it should be, supposing the exact interchangeability always held good; but it has never been found that a light was so feeble that no action could take place. Of course it must be borne in mind that the stability of the substance acted upon may have some effect; but the same results were obtained with matter which is vastly more stable than the ordinary silver salts. It may be said, in truth, that almost all matter which is not elemental is, in time and to some degree, acted upon by light.

I should like to have said something regarding the action of light on the iron and chromium salts, and so introduced the subject of platinotype and carbon printing, the former of which is creating a revolution in the production of artistic prints. I have, however, refrained from so doing, as I felt that the President of Section A should not be mistaken as the President of Section B. Photogravure and the kindred processes were also inviting subjects on which to dwell, more especially as at least one of them is based on the use of the same material as that on which the first camera picture was taken by Niepce. Again, a dread of trenching on the domains of art restrains me.

Indeed, it would have been almost impossible, and certainly impolitic, in the time which an address should occupy, to have entered into the many branches of science and art which photography covers. I have tried to confine myself to some few advances that have been made in its theory and practice.

The discovery of the action of light on silver salts is one of the marvels of this century, and it is difficult to overrate the bearing it has had on the progress of science, more especially physical science. The discovery of telegraphy took place in the present reign, and two years later photography was practically introduced; and no two discoveries have had a more marked influence on mankind. Telegraphy, however, has had an advantage over photography in the scientific progress that it has made, in that electrical currents are subject to exact measurement, and that empiricism has no place with it. Photography, on the other hand, has laboured under the disadvantage that, though it is subject to measurement, the factors of exactitude have been hitherto absent. In photography we have to deal with molecules the equilibrium of whose components is more or less indifferent according to the process used; again, the light employed is such a varying factor that it is difficult to compare results. Perhaps more than any other disadvantage it labours under is that due to quackery of the worst description at the hands of some of its followers, who not only are self-asserting, but often ignorant of the very first principles of scientific investigation. Photography deserves to have followers of the highest scientific calibre; and if only some few more real physicists and chemists could be induced to unbend their minds and study the theory of an applied science which they often use for record or for pleasure, we might hope for some greater advance than has hitherto been possible.

Photography has been called the handmaid of art; I venture to think it is even more so the handmaid of science, and each step taken in perfecting it will render it more worthy of such a title.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 7	Carlisle and County	Cathedral Hall, 57, Castle-st., Carlisle
" 8	Newcastle-on-Tyne & N. Counties	Mosley-st. Café, Newcastle-on-Tyne.
" 8	Derby	Society's Rooms, 3, Derwent-street.
" 8	Bradford.	55, North Parade.
" 8	Manchester Amateur	Manchester Athenæum.
" 8	Bolton Club	The Studio, Chancery-lane, Bolton.
" 8	Photographic Club	Anderson's Hotel, Fleet-street, E.C.
" 10	Birkenhead	Free Public Library, Hamilton-st.
" 10	Cheltenham	
" 10	Manchester Photo. Society	36, George-street.
" 10	London and Provincial	Masons Hall Tavern, Basinghall-st.
" 11	Ireland	Royal College of Science, Dublin.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 26.—Mr. Freshwater in the chair.

Mr. H. D. ATKINSON inquired whether there was known to be any fading away of an undeveloped image upon very rapid plates. He had recently, during a journey, exposed several plates, and whilst those of ordinary rapidity developed properly, those of the extra rapid kind only gave a faint, ghostly image.

Mr. ARCHER CLARKE said that the ordinary plates of one of the commercial makers proved to be more rapid than those marked as extra rapid. If that was the make in question the probability was that the faintness of the image was merely due to under-exposure.

Mr. F. A. BRIDGE said that there was no chance of the image having faded. Mr. ATKINSON replied that plates of the same sample worked properly before going away.

Mr. Hastings showed a print from a negative taken with a shutter asserted to work in the one-two-hundredth part of a second. The negative was taken from a railway carriage whilst travelling at the rate of sixty miles an hour, and only on close examination was any want of sharpness noticeable.

In the course of a short discussion on orthochromatic plates, Mr. A. HADDON said that he had noticed that in some subjects in which there was reflection from water the orthochromatic plate yielded the better result by far.

Mr. C. H. COOKE inquired whether any member had found a greasy spot towards the edge of platinotype paper. He had done so, and attributed it to the greasy compound used in the tins for making the joints air-tight.

The CHAIRMAN would like to know the real cause of the blistering of some dry plates. He had recently opened a packet which gave him a good deal of trouble in that way. It was a make that took long in fixing.

Mr. CLARKE recommended a weaker fixing bath.

Mr. P. EVERETT inquired whether a statement by Mr. George Smith, that two plates, one of which had received three times the exposure of the other, could not possibly be developed to be at all alike, was in accordance with the experience of the members.

The opinion was generally expressed that negatives with these diversities of exposure could be developed so as to produce prints which could not be distinguished from each other, although the colour and appearance of the negatives might be different.

Mr. EVERITT having spoken of the slow printing character of yellow negatives,

Mr. W. E. DEBENHAM said that, if the shadows were clear, he could not see why a negative which owed its printing density to a yellowish colour of a thin deposit should print more slowly than one which owed its density to a thicker deposit of a grey or neutral colour.

In confirmation of this view, Mr. COOKE said that he had a negative almost gamboze in colour which printed quickly.

Mr. ATKINSON had also a negative that was of very non-actinic colour, having been intensified with mercury and Schlippe's salt, which printed quickly; and Mr. BRIDGE had a similar experience with a yellow mercury-intensified negative.

Mr. HADDON could find no reason for slow printing in yellow negatives, provided the yellow colour was confined to the deposit, and was not a general stain all over the film.

This view was contested by Mr. EVERETT, but was generally accepted by the members.

A question was read:—"If a plate has received the correct exposure, is there any advantage in developing with a brush?"

Mr. J. J. BRIGNSHAW said that there might be. If the plate had been exposed on a subject having such violent contrasts that, with the best exposure as a whole, there were parts over or under-exposed, brush development might be employed with advantage.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

SEPTEMBER 23.—Mr. E. T. Hiscock in the chair.

Mr. A. Le Viege exhibited prints, also a Chronolux shutter by Messrs. Lancaster & Son.

Mr. S. T. Chang exhibited one of Shew's Eclipse detective cameras.

The CHAIRMAN then called upon Mr. Bishop to demonstrate the transferotype process.

Mr. BISHOP: The advantages claimed for this process are, that it allows of an image being developed in the ordinary manner, after which it may be transferred to any surface thought desirable; it is also one of the easiest and quickest methods of making a reversed negative for mechanical processes; window transparencies may be made cheaper than by any other method; and it is also claimed for it that it is useful for making lantern slides. The *sine qua non* of a lantern slide is that it shall be absolutely clear in the high lights. It is here that this process fails, for, as you will notice in the specimen before you, the gelatine is covered by a fine granularity or reticulation. The Eastman Company say that this is of no consequence, as it does not show when projected upon the screen, but it *does*. Among the different things to which the image may be suitably transferred are opal, plaques, tiles, lamp shades, ground glass, panels, vases, &c. The paper is made by being first coated with a soft, soluble gelatine which, when dry, is then coated with the sensitive emulsion, which becomes insoluble when dry. After exposure to light, which is about the same as for bromide paper (that which I have here for development having had one second to weak daylight late in the evening), it is developed with the ordinary oxalate of iron developer; it is then put into a bath of acetic acid and water (strength: one part acid, two hundred and forty parts water); after which it is fixed, washed, and then squeezed into contact with the surface to which it is intended to fix it; it is then blotted and placed on one side to dry for half an hour, when it is ready for stripping, which is done by pouring hot water on it, which, soaking through the paper, dissolves the soluble substratum of gelatine and allows the paper to come away, leaving the film attached to the surface of the article, when all that remains to finish it is to wash off the partly dissolved gelatine still adhering to it. For this I prefer a large camel's-hair brush (known as a water-colour wash brush), as being less likely to leave any pieces behind. The lecturer then proceeded to illustrate his remarks by developing a print, after which he transferred about half a dozen of different sizes—some to opal, others to ground glass.

The question was asked as to the reason for letting the print dry for half an hour on the surface of the glass before stripping.

Mr. BISHOP replied that if stripped before that time there was a probability of the film leaving the support, which he illustrated by stripping one which he had a few minutes before squeezed into contact, the result being that the picture frilled slightly at the edges.

It having been remarked that this process gave reversed results, Mr. BISHOP said that this might be overcome in several ways. First, those who used film negatives would find no difficulty whatever, as they could be used from either

side; or if the stripping films were used for negatives these would be reversed, and so give the resulting print in the proper position: another method, of which several examples were shown, was by copying the negative in the camera, glass towards the lens. Mr. Bishop also mentioned that he and Mr. Jackson, of the Eastman Company, had carried on several experiments with the hope of being able to effect the double transfer, and although they had been partly successful, the results were not good enough to recommend the method. Another way which he had tried himself, and which he illustrated, was to place the developed print in the hot water without squeezing to anything, and so float the image off without support, when it might be turned and placed in position on whatever article it might be desired to fix it; if, however, this method was used it was necessary to print very much darker, as a quarter-plate print would expand until it covered a half-plate, thus causing the print to be much lighter when finished.

Mr. FITHER: Can the tone obtained be modified in any way?

Mr. BISHOP: Mr. Jackson had used pyro and soda in some experiments, by varying the proportions of which he found it possible to alter the tone.

The SECRETARY: Would it not be possible to proceed in the usual way, and when finished change the tone by the various methods of intensification?

Mr. BISHOP: Of course they would be just as amenable to any after treatment as other processes were.

At the next meeting Mr. S. Herbert Fry will give a demonstration of *Enlarging*.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

SEPTEMBER 6.—The President (Mr. F. W. Edwards) in the chair.

Seven members were elected and one proposed.

Further contributions of lantern slides were made by Messrs. Dowling, Gardner, and Kelly.

A large number of prints and negatives were handed round for inspection, amongst them some fine 24×18 platinumotypes by the President.

Next meeting, on Friday, October 5, at 76, Peckham-rye; paper on *Lens's*, by the President.

BATH PHOTOGRAPHIC SOCIETY.

SEPTEMBER 25.—Mr. Austin J. King in the chair.

Messrs. J. Arnold, H. H. Ricketts, and E. S. Southwell were elected members.

The HON. SECRETARY announced the receipt of thirty-five copies of *The Principle of a Lens Action* (Taylor, Taylor, & Hobson), thirty-six copies of the *Photographic Review* (Bolas), a package of *Practical Hints and Calendar* (Tylar), a tin case of eikonogen (Marion & Co.), and samples of dry powder developer (Oldham), for the use of the Society.

Mr. BRAHAM then addressed the meeting on *The Work of the Paris Congress*. He stated that Mr. Friese Greene and himself, the delegates appointed by the Society, were heartily received by the Congress. The remarks in some quarters that a high subscription was demanded, was untrue; they were not asked to pay anything. He looked upon this Congress as the commencement of an important era in photographic history—the beginning of a more scientific manner of working. Little was actually settled, yet that little was fraught with good. The first question dealt with was the unit of light. Hitherto much depended on chance; correct exposure was pretty much accidental; the sooner a definite measurement was substituted the better for everybody. Several proposals were before the Congress, two of which were referred to a committee, namely, an amyl-acetate lamp fitted with a spiral of platinum wire, and a given amount of electric current. Upon the question of focal length, one-tenth the principal focus was determined upon as the unit. The Whitworth thread was accepted. It is formed by an angular section having an angle of 55° . Mr. Whitworth found by experiment that that angle held best to the metal. The ready attachment of lenses to cameras was a thing which often bothered photographers. The most ingenious plan submitted to the Congress was merely a zinc plate with a hole cut for the lens tube to pass into, and a nut screwed on the lens from behind to fix into the camera. This he thought the best plan. Plates measuring 18×24 c.c. were considered the best size for reducing to other sizes economically. Upon the question of expression in formulae, Mr. Braham said that some of the members regarded the English as too stubborn to adopt the metric system; but he explained to them that all educated English would only be too glad to have the system adopted. Two propositions were mooted for safe transit of plates through the Customs—one the attachment of a special label, and the other examination in a suitable room in the presence of the owner. A number of difficulties might arise in either case. There was a good deal of discussion, and he hoped it would have a beneficial effect upon the general transit of goods from one country to another.

The CHAIRMAN thanked Mr. Braham as a delegate as well as for the interesting account of the work done. Many of the subjects discussed were of great importance. He did not find much difficulty with the Customs, although some half a dozen men had quarrelled with the officers. One man was found to have a lot of tobacco after he declared he had none at all. Personally he had passed cameras and quantities of slides into Spain, Holland, and elsewhere, and the only case happened with a new camera, for which they asked duty until he found it was slightly scratched by the tripod head. He did not approve of a special label method. The Society was also much indebted to Mr. Friese Greene for acting as the Society's delegate in Paris, and also for being present to report on the London Convention, at which meeting he was the Society's representative.

Mr. GREENE thought the most interesting exhibit at St. James's Hall was the book of Talbot's calotypes, sent by the Bath Photographic Society. It was a pleasure to watch the old photographer looking at the pictures and wondering why they had kept so well. Indeed, there were few to compare with some of these made forty years ago. The improvement was in quickness, not in quality. *The value of the book has been assessed at 100l.*

Mr. Greene passed round a platinum print of the Convention group, 20×16 . The exposure was two seconds, $f/8$, and a copy was presented to the Society. Mr. Greene exhibited examples of bromide printing on opalescent celluloid

stamped in sundry ornamental designs. These were considered effective. He also handed round similar prints on ordinary mounts (opal cards) made by artificial light direct from negatives.

The CHAIRMAN, having thanked Mr. Greene, said the outdoor meetings of the season had ceased, and he wished to thank the Excursion Committee for the trouble bestowed in making the arrangements.

Mr. BRAHAM said the outings had been most enjoyable; they had advanced the popularity of the Society and redounded to the credit of the organizers. Every possible condition had been met.

MANCHESTER PHOTOGRAPHIC SOCIETY.

SEPTEMBER 12.—Mr. John Schofield (Vice-President) in the chair.

Mr. THOMSTONE said he had recently developed a number of landscape negatives with eikonogen, and was very much pleased with the results. He considered it slower in action than pyro and ammonia.

Mr. ABEL HEYWOOD, JUN., had tried eikonogen for transparencies, and thought the results were very similar to those developed by hydroquinone, which he considered was the developer for transparencies, because the shadows were more of the character of a stain, and not so opaque as those developed with pyrogallol acid; and, therefore, did not consider hydroquinone so good as pyrogallol for negative development.

Mr. R. ATHERTON had developed a good many transparencies, both stereoscopic and for the lantern, with eikonogen, and was very much pleased with the results. With Mawson's lantern plates he obtained a most pleasing tone, and any variation in exposure did not seem to alter the colour. He considered it the best of all developers for transparencies, and handed round a number of lantern slides developed by it.

The HON. SECRETARY (Mr. W. I. Chadwick) wished to confirm all that had been said in favour of eikonogen for developing transparencies. He had developed twenty-four stereoscopic transparencies, using only four and a half ounces of solution, and still the solution was by no means exhausted.

Mr. D. E. BENSON inquired as to the best lenses and their arrangement for micro-photography.

After several opinions had been given, Mr. Benson was referred to Mr. G. J. Johnson, a member of the Society (not present), who had done some splendid work in this branch, and who was considered an authority on the subject.

Mr. H. Smith exhibited a hand camera for stereoscopic work and some slides which were produced by it. The camera body was constructed out of an old stereoscope, the lenses three and a quarter inches focus, of the single landscape type, working at $f/12$, with a simple slide shutter actuated by an elastic band. The instrument, which was "home made," was very much admired for its simplicity and inexpensive and novel character.

Mr. ATHERTON read the following communication from "our old and respected President," the Rev. Canon Beechey:—

TO THE MANCHESTER PHOTOGRAPHIC SOCIETY.

[Adventures of a Photographic Amateur, Lausanne, May, 1889.]

FYITE I.

Lausanne! What a treat for a lover of art!

"What scenes photograph I shall carry home!"

So I said when I made my first artistic start,

Determined at once to the mountains to roam.

My light satchelled camera hung on my back,

My slides in a neat little bag were contained;

Most careful that nothing I wanted should lack,

My daughter went with me, and with me remained.

A nice walk we had for a couple of miles,

But nothing we saw which a picture would make;

My daughter was all conversation and smiles,

And nothing amiss I could possibly take.

At length to a sweet little valley we came,

Where there flowed a brig-t, swift, rippling rill;

No longer the landscape, though lonely, was tame,

For there in the vale stood a picturesque mill.

'Twas a quaint-looking building, essentially Swiss;

Behind it the hills rose all covered with trees,

Beneath it the river did bubble and hiss,

And large boulders lay as determined to please.

Then down came the lasses—the miller's fair maids,

And the miller himself, a fine, handsome man

(And a miller is merrier than all other trades);

And the whole were all posed as correct as a team.

So a picture was taken, a stereo as well,

And the camera packed in its satchel quite close;

But when all was prepared to forsake the wild del.

As to how to return a hard problem arose.

For the way down was steep, and the dell-side soft clay;

To get down had been hard, but much harder to climb;

'Twas clear we must look out for some other way

If we wished to get home to our dinner in time.

Now the dear little river still murmured below,

And seemed to exclaim, "Why not leap over me?"

And the miller, too, offered a plank to bestow,

Where the water dashed down in a fall, fell to see.

But to get there a passage of stones must be made,

And then a small leap to the plank must be ta'en.

My daughter the effort first safely assayed,

And soon I endeavoured to make it again.

But, alas for the fortunes of art and of age!

The stone which I sprang from roll'd under my feet;

In vain the held staff would my tenure engage,

For my legs were borne down by the current so fleet.

To go down a cascade is not pleasant at all,

And what it would end in is hard to suggest,

For I found myself rapidly drawn by the fall,

And the water already was up to my chest.

Then swiftly I made a bold clutch at the plank,
And, as fortune would have it, I got a good hold;
My feet to the bottom then rapidly sank,
Then out of the flood so seaward safely I rolled.

(End of Fytte I.)

FYTTE II. (The metre changes.)

When you go for an out in the time of your leisure,
The thing which you look for is, certainly, pleasure;
To growl and to grumble at little mishaps
Is what no one will do but the stupidest chaps.

So onward we walked still, my daughter and I,
Determined to laugh, and not, certainly, cry.
After all, when we'd made our bitterest structures,
Were we not going home with two beautiful pictures?

We had promised to send off the earliest print
To the courteous miller: and I would not stint!
Either pains or expense to make that print good,
But to tend and develop as well as I could.

What pleasure might happen from any new view;
This was deepest interest would always renew;
The thoughts of the day would come home to our mind,
And the view and the ducking for ever be joined.

Arrived at our pension, in dry clothes arrayed,
A hearty good dinner we certainly made;
And I, like a bird who'd escaped from a trap,
Lay down and snoozed on in a very sound nap.

Then waking, I knew by the count of the chime,
To go and develop would soon be the time.
And here to my friends I must hasten to speak
Of the *Société Lausanno Photographique*.

For no sooner they heard there was here in their town
Your ex-President, who they thought was a *frère* of renown,
Than they placed at his service whoever he might choose,
Their dark room for change and developing use.

So down there I went with my dark slide in hand;
Key and candle were placed at my instant command;
And I shut myself in, lit the lamp, and prepared
To develop the pictures for which I cared.

All the chemicals ready, the dishes all right,
I carefully shut out the least ray of light,
Then opened my slides, the first plate to prepare,
When, ah! what a sight! It made both my eyes stare.

"Why, what can have happened?" You'll hear in a minute:
When I opened the slide, why, no plates had been in it!
Here I think you'll all cry out, in accents so quick,
Why, who could be guilty of that stupid trick?
O friends photographic, don't scream, I beseech ye!
'Twas your own old ex-President, ST. VINCENT BRECHER!

Lausanne, May 29, 1889.

The members were reminded that the next meeting would be the annual meeting.

Messrs. W. J. Cunliffe and H. M. Whitefield were elected Auditors, and the few members who had not paid their subscriptions were requested to do so.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 20.—Mr. H. A. H. Daniel (President) in the chair.

The resignation of Mr. J. Healey, Corresponding Member of the Association, was tendered and accepted with regret.

It was proposed that a competition should be started amongst members for the best half a dozen lantern slides, to be brought in at the ordinary March meeting, 1890, which should be arranged as a lantern evening and *concerto*.

Mr. W. C. HEMMONS suggested that the services of one or two good demonstrators should be secured for some of the monthly meetings, which might be more or less popularised and rendered open.

The PRESIDENT said the officers of the Association would be glad to make inquiries with a view to some such arrangements, and he hoped that at an early date some announcement might be made.

The meeting then resolved itself into free discussion and exhibition of summer work.

Prints were shown in platinotype, bromide, and albumenised silver, by Messrs. Brightman, Norgrove, Hemmons, Lavington, Bond, and Hutchinson. Colonel Playfair showed some very good negatives.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 26.—Mr. A. W. Beer in the chair.

The PRESIDENT drew the attention of members to the arrangements respecting the competition prints and lantern slides, and announced that the following gentlemen had kindly undertaken the duties of adjudicating and awarding the prize medals offered by the Association, viz.: Messrs. George W. Webster, John Finnie, and E. R. Dildin, for prints and enlargements; and Messrs. George E. Thompson, E. L. Grundy, and Paul Lange, for lantern slides.

A "smoking social" will be held on October 18 at a quarter to eight p.m. There would also be a "social" in November.

Mr. FORRESTER submitted an Eastman bromide print developed by hydroquinone, the result being very favourable; also a specimen lantern slide upon Carbutt's cellulosid film.

Mr. GEORGE E. THOMPSON referred to Thomas's lantern plates, that he had experienced many instances of yellow fog; he had written to the makers, but their reply was not altogether satisfactory. He found where development had

to be retarded yellow fog was almost sure to result, but when the details came up quickly there was no fog manifest.

The PRESIDENT said he had used many dozens of Thomas's plates during the season, and, from his experience, was convinced the plates were all right, but the developer was often wrong. He found the formula, as given, deteriorated, and the same might be said of eikonogen. When fog and loss of brilliancy appeared he at once made up fresh developer. With regard to the warm colour for lantern slides, he found that with a very strong negative fifteen to twenty seconds' exposure (by contact) to daylight gave a beautiful terracotta or warm brown colour by either the hydroquinone or the Thomas's pyro formula.

Mr. THOMPSON said he obtained the most satisfactory warm tone with pyro, carbonate of ammonium, and bromide potassium.

Mr. THOMPSON then gave his lecture, entitled *Rambles along the Riviera from Marseilles to Genoa*, the result of a three weeks' visit in February last. The slides are quite up to the high level of artistic excellence attained by him in *Up the Mediterranean*, *Sunny Italy*, and *The Waterways of Holland*. This admirable series of views, coupled with Mr. Thompson's inimitable and humorously attractive delivery, gave great pleasure to his audience, evoking applause from time to time during the evening.

Correspondence.

Correspondents should never write on both sides of the paper.

THE LATE CONVENTION.

To the Editor.

SIR,—Now that the exchange of personalities between the critics of the recent Convention and its defenders is about played out, it may, perhaps, be permitted to me to allude in a more general and practical way to the (to me) apparent reasons of its want of success.

The whole conduct of the Convention seems to have been characterised by an entire absence of business aptitude in its moving spirits; true, on glancing over the list of the Council we find many able and practical men, but, unfortunately, the management of the whole affair seems to have been left to the less capable of its members, doubtless owing to the impossibility of the more capable and representative members of the photographic world having their time filled by their personal occupations.

At the dinner of members of Convention Mr. Pringle communicated to the members what he evidently considered a congratulatory matter: that it was hoped and expected, on settling the accounts, the result would be that the Convention this year had paid its way. I must say that from my point of view such a statement, far from being a subject for rejoicing, seems to be an acknowledgment of dire failure. Excuse has been made for want of more success on account of the absence of *everybody* from London; well, perhaps this is true in a limited social sense, but there still remained, say, 4,750,000 inhabitants from which to recruit a *clientèle*.

Let us inquire what efforts were made to enlighten this population on what was occurring in its midst. Only two days before the opening ceremony was the programme in the hands of subscribing members. Even then it was very meagre in its details. On looking it over I noticed three blank pages—two inside and one outside the cover; it at once struck me, as it would any one with a fair amount of common sense, that the Council might have taken a good number of sovereigns by letting these pages for advertisements. I asked a member thereof why this had not been done; he told me they had an offer of 5*l.* for one page on condition that they would guarantee a certain issue, and that this it would not have paid the Convention to do. It does not seem to have entered into the minds of the active managers that had they placed the matter in the hands of an advertising agent he would easily have obtained them a dozen or two pages of trade advertisements, which would have enabled them to give any guarantee of number printed which might reasonably be necessary.

Then the desire of the ruling spirits seems to have been to judiciously hide their light under a bushel, or, I should rather say, in a dark cellar, lest one ray should illumine the world and show their existence, for, according to their own statement, *they issued no free tickets to the press*. Let me write it again; it is so charmingly ludicrous—*they issued no free tickets to the press*. With what result? An occasional corner paragraph regarding the Convention on one or two occasions seems almost by accident to have crept into some of the daily newspapers, instead of the proceedings being daily reported, freely as they would no doubt have been had the press been properly treated. Then the fiasco about the withholding of the reports from the technical papers; I say nothing regarding the manner in which they subsequently appeared, as this seems to have been the Benjamin's mess of the whole proceedings, but by everything in heaven or upon earth I am quite unable to see the object of the first intended delay in publication, and I have, up to now, not succeeded in finding any one who could enlighten me on the point, and, therefore, can only come to the conclusion that it was a further exemplification of the desire to hide the existence of the Convention from those whose support it required.

Now let us see what the Council did in the way of advertising its session. I found nowhere in the usual channels any prominent notice of any kind whatever, but on asking a member of the Council about it, he told me that it was advertised *all the week (!) at each Metropolitan*

Station. Well, I am in two or three of the Metropolitan Stations daily, and generally having to wait for my train, look about me a good deal and amuse myself with inspecting the numerous attractive posters, &c., displayed there, but never saw one relating to the Convention till the day before its close, which consisted of a poster of a nice retiring French grey colour, placed in the position least frequented by waiting passengers; and I only noticed this by the accidental attraction of a cross slip in red letters stating "Now Open" being pasted over it. It reminded me of the story of the lady who, owing to reduced circumstances, was compelled to cry watercresses, and always supplemented her call by saying, "I hope nobody will hear me."

We have been told, as a matter of complaint from the Council, that certain delegates did not take up their membership, and paid their shilling at the door like one of the public. Who is to blame for this but the Council? They ought certainly to refuse to receive any nomination of a delegate not already a member.

Now, with the aforesaid public of about four and three quarter millions to work on, what do we find? The President congratulating the Conventionist on making both ends meet, instead of the Convention, if managed with business aptitude, resulting in a balance, as it should, of one or two thousand pounds to the good.

I think some alteration ought to be made in the manner of selecting delegates from the Societies; at present the idea does not seem to be to send representative photographic notabilities so much as to take any member who is supposed to be able to give a considerable amount of time. I know of one Society, with many members of high standing in the photographic world, which sent two representatives. No. 1's claim to distinction is, apparently, that on one occasion he read a paper on a reducing agent, which was subsequently shown from all informed quarters to be entirely misconceived; and No. 2's claim to notoriety is, so far as I can see, that he disturbs the meetings of his Society with —. If the Local Committee is nominated on these lines to any extent, it is not to be wondered at that the results are unsatisfactory.

I notice in the Convention programme ten recommended hotels, it would be interesting to know whether the proprietors of these establishments paid any advertisement fees for the insertion of their tariffs, or whether the Council made them a free gift of their space and printing—I am, yours, &c.,

CONVENER.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—My friend the enemy is still not satisfied, and, I am beginning to fear, will never arrive at that happy state. Wicked quotations will crop up, and, as I don't want to be too naturalistic in manner, I apologise for this one beforehand; I am sure of my friend's forgiveness. Does it not strike you that "Gratiano talks an infinite deal of nothing," and that your readers must be getting tired of this "unreal mockery" of a controversy? I will endeavour to encourage my pleasant opponent into one more reply, and the rest I hope will be silence as far as I am concerned.

Mr. Davison says that imagination to him means absolutely nothing. I was quite sure of this, but it is not our point at present. What I and many others want is a clear and sensible definition of what naturalistic photography really is. We don't want Mr. Davison's airy "gibe" of a former letter, that it is "the best of everything"; we don't want to know what it is not; we don't want merely destructive criticism; we don't want to hunt for it through the tedious pages of a voluminous treatise; all we want from Mr. Davison is a clear and concise definition of what naturalistic photography really is. It surely must be within the resources of a clever writer to gratify us in the compass of a column or two of THE BRITISH JOURNAL OF PHOTOGRAPHY.

It cannot be what we have all thought it to be if Mr. Davison practises what he preaches. In the present Exhibition, near the door, is a group of pictures—real pictures—by this admirable artist which will command the admiration of all who see them. Mr. Davison condemns combination printing in the most unmitigated manner, sometimes with a frenzy which almost carries one away and makes one determined to sin no more; yet—it is almost incredible—many of these pictures owe their beauty to combination printing. So skillful a combination printer is Mr. Davison, that I should never have found him out if I had not detected the use of one sky negative in two different pictures. I have always condemned this practice as against nature; can Mr. Davison justify it? Then, again, my friend scoffs at pictorial composition as it has been understood and practised for many years, yet many of these pictures are composed admirably according to the strict rules and laws made and provided. Who can fail to see the subtle use of the balancing point? The chiaroscuro is sound throughout, and the definition as sharp as his lens could make it. When a disciple denies his master to this extent, he must not be surprised to hear the cock crow! In theory Mr. Davison may be a naturalistic photographer; in practice I claim him as an artist.

I will not reply at length to his allusion to "attempts at historical subjects." He has, doubtless, read *Pictorial Effect and Picture Making*, and knows that in both books, and in other places, I have condemned any attempts of the kind in the strongest language that may be permitted to any but a naturalistic writer.

The next novelty, I hear, is to be the Tuning-fork School of Photo-

graphy; the fork being used during exposure to make the camera "dither," and thus produce the blurriness of nature as seen by the naturalistic eye.—I am, yours, &c.,

H. P. ROBINSON.

Tunbridge Wells, September 28, 1889.

STANDARD MEASUREMENTS FOR LENS FITTINGS.

To the Editor.

SIR,—It appears to me a pity that Mr. William Taylor did not make himself acquainted with facts before writing his *apologia* to you in the matter of his motion that the report of the Lens Committee be not adopted. I believe, sir, you were present when the motion was put—but I say so, liable to correction—while Mr. W. Taylor's remark that you (of all men) might misunderstand him is to show how little he really appreciates your "vast powers." I flatter myself I move considerably more in photographic circles throughout the United Kingdom than does your correspondent, but I have not met with any of the "deplorable misunderstanding" he would have you believe exists. Perhaps it will surprise Mr. Taylor if I state that the report was, as a matter of fact, the report of the Convention Committee, properly convened and properly constituted, all the members in London attending; that the report in draft was approved—with but a slight alteration—by the only available members at the time it was drawn up. It is, therefore, not "Mr. Wollaston's report," as would be gathered from the natural interpretation of his letter.

The "incompleteness," "disgracefulness," "grossly bad expression," and "impotency" of the report were clearly matters for the Council to take cognisance of, if they thought fit, and it was their business to alter, amend, or even reject it altogether, else why the rule to that effect? Mr. Taylor's opinion on these matters has not been asked, and, being gratuitous, it verges on insult to the Council. His self-satisfied remark that he is one of a happy few who know the correct specification of the standard screws again shows his low appreciation of others' brains and work. It certainly was not within the province of the Committee to specify in the report.

Coming to a more personal remark in this wonderful letter, Mr. Taylor would have you and your readers believe that I, "who professed such enthusiasm at Birmingham, should have so damned it" (the work of the Committee) myself. For his enlightenment I may tell you, Sir, without fear of contradiction, that I am not one whit less enthusiastic than I was on this question, but that, as I am entirely of his opinion that "public demand is the only thing possible for his (the optician's) conversion, or for any general agreement," I am doing my level best to bring about the object we both aim at by educating that public rather than by the reading of papers or the writing of reports, although these assist. I fancy I could satisfy even Mr. William Taylor that the course I am now adopting is preferable to the work of committees and such-like organizations, simply by a peep at my correspondence and my press-copy letter-book.—I am, yours, &c.,

S. G. BUCHANAN WOLLASTON.

Lennie, Chislehurst, Kent, September 28.

"EIKONOGEN."

To the Editor.

SIR,—Having made a few experiments with the new developing substance, eikonogen, I should like to lay them before your readers, hoping others will follow my example, as it is only by thus comparing results that we can form an opinion as to the definite position the new compound is destined to fill as a photographic developer.

On reading over the paper enclosed in the packet it seemed to me that the principal claim made for eikonogen was its great developing power; therefore, in all the plates I exposed I gave a very short exposure. The first formula I tried was one published in your columns by Messrs. Fradelle & Young. I found no difficulty in dissolving the eikonogen in the amount of water necessary to make a ten per cent. solution; but the substance in no way resembled the description given of it in the paper accompanying it, namely, "a white crystal powder"—it was a dirty grey, very like ashes; when first mixed it formed a brown solution, but gradually became a clear bottle-green. I used it as directed, without any addition except the sulphite of soda. After waiting some five minutes a trace of sky appeared, but the progress was so slow that I added some carbonate of soda, and the image came up gradually. On fixing it proved grey, and wanting both in density and detail.

For the next plate I added the soda carbonate before commencing, and the image came up something quicker; but I had to add a few drops of a solution of caustic soda, even then it was but a little better than the first. A very over-exposed image might, perhaps, be developed with the addition of sulphite only, as indeed it can with pyrogallol; but I am convinced that an under-exposed one would take hours.

I next determined to use caustic soda as the accelerator, and made up my solutions on the lines of Thomas's hydroquinone developer, only leaving out the citric acid. Again, I had to wait an abnormally long time before the image appeared, though there was a large amount of the caustic alkali present, which its printed directions describe as *too powerful*. The resulting negative was better as regards density and brilliancy,

but did not possess as much detail as a plate with the same exposure developed with hydroquinone, same formula. After development the eikonogen solution had become a dark brown, the hydroquinone remaining almost colourless for many hours. There was a marked yellow stain on the plate when fixed, but it rapidly disappeared in washing, the water becoming a brick-red colour. It was evident to me that the soluble bromide contained in the developer had an *extremely* powerful effect when combined with eikonogen, so I next made up a developer without any restraining bromide, the formula being:—

Eikonogen	20 grains,
Sulphite soda	45 "
Rain water	5 ounces,
Caustic soda	20 grains,
Rain water	5 ounces,

mixed in equal parts. On applying to the plate the image came up a good deal quicker, and in about eight minutes was completed, and proved the best I had produced. The developer was, however, so dark in colour that I would not like to have attempted to use it for a second plate.

From these experiments I would conclude that eikonogen is decidedly less powerful than either pyrogallol or hydroquinone, and more strongly affected than either by a restraining bromide. It gives a bright, soft image, and would seem less apt to give over-density than hydroquinone, but beyond this I can see no advantage in using it until some more satisfactory formula is discovered for compounding the developer. We must not forget, however, that the first formula given with hydroquinone were very uncertain, their powers having also been much over-estimated.—I am, yours, &c.,

GEORGE MANSFIELD.

To the Editor.

SIR,—I can endorse the statement of your correspondent, Mr. J. Gardner, re solubility of eikonogen. Having a doubt about the possibility of dissolving so large a quantity as ten per cent., I prepared a solution, or rather a mixture, according to the formula of Messrs. Fradelle and Young, and was careful to completely dissolve the sulphite of soda, before adding the eikonogen. However, I found that there was a white crystalline deposit occupying about one-fifth of the bulk of solution, which no amount of persuasion could induce to dissolve.

For instantaneous exposures, I find the strong solution of eikonogen recommended by Messrs. Marion & Co. particularly suitable; but I prefer two solutions instead of the one, as it keeps so much better when separate.

My formula is the same as Marion & Co's No. 3, except that I omit the potash. The alkaline solution is made up eight times the strength, namely, caustic potash one and a quarter ounces to five and a quarter ounces of water. For use, take one ounce eikonogen solution and add one drachm potash solution. This brings it very nearly the same strength as the one solution, with the advantage of being able to increase or diminish the quantity of alkali, and also enhancing the keeping quality.—I am, yours, &c.,

J. DEARÉ ENGLAND.

21, Charles-street, Royal Crescent, Notting Hill, W.

MOUNTING PRINTS.

To the Editor.

SIR,—In your report of the "London and Provincial Photographic Association" of September 19 the Chairman has computed that I said, I "always pasted paper on the back of a mounted photograph." This is hardly correct. The Chairman may have heard me state at one of the evenings of the Photographic Club that "one way to keep photographs flat when not mounted on cardboard was to paste a thin tissue paper on the back"—this is one of the best methods I have used, and it answers very well. The proper way is to damp the tissue in order to stretch it as much as possible, paste the silver prints with starch, lay it down on the tissue, to which it will at once adhere, the tissue may then be rubbed down quite flat. Another way to mount on cardboard and not to cockle, other than starching or gumming and allowing to dry, is to mount the print on paper the full size of the board, and, while damp, to paste the whole on the cardboard (now called the middle), another paper pasted to the back of middle, and the whole, when dry, placed in the press, or rolled; they will then be perfectly flat.

The question of mounting prints is always a serious one for amateurs; for this reason I put into the market my album, each leaf of which is single, and can be detached for mounting on. In my opinion, as a practical man, any ordinarily-bound album is of little use for photographic purposes; the leaves cannot get dry properly, and there is always danger of setting up chemical change and engendering spots.—I am, yours, &c.,

J. W. ZAEHNSDORF.

CELLULOID FILM PRINTS VERSUS HEAT.

To the Editor.

SIR,—Rather an amusing circumstance occurred on Wednesday last at the tea-and-coffee section of our Liverpool Photographic Club, which meets weekly. Holding up a film print by Mr. Tomkinson (one of our members), the size of a lantern slide, I said, "Why should this not be

used for lantern slides?" One of our notable members cried out, "It would never do, for it would melt by the heat of the lantern!" Another member said, "Don't you know it is made from gun-cotton, it would be sure to explode!" In reply, I said, "I differ from both of you, and will prove my statement at the earliest period."

The following day I put pieces in the kitchen fire up to 5 × 4, and it only burned like ordinary paper. The same evening we had a lantern exhibition, and I got Mr. Phillips (who was operating) to pass it through the lantern, and it came out without the slightest change. The great drawback to the advance of film (celluloid) photography is its high price. I name this with the view of getting manufacturers to remove this grievous obstruction to its adoption.—I am, yours, &c.,

JAMES ALEXANDER FORREST.

Waverley, Alexandra-road, Birkenhead, September 30, 1889.

LANTERN SLIDE MAKING.

To the Editor.

SIR,—Referring to a report of a paper read by me before the Birmingham Photographic Society, appearing in your issue of September 20, I notice an error in the formula of the iron developer for wet plate transparencies. The amount of water should be 8 ounces, not 16 ounces.—I am, yours, &c.,

E. HOWARD JAKES.

THE ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION.

To the Editor.

SIR,—In your impression of September 20, 1889, you publish a report of the above Society's Exhibition at Falmouth, and under the heading "Photographic Appliances," you refer to two cameras which I exhibited, and from a remark there made would lead one to suppose they were of a complex nature; whereas they are extremely easy to use and set up, although containing several novelties in construction.

The Judges evidently did not give them a thorough examination. I also sent with them a written description, which shows no signs of having been read.

The cameras in question are certainly of a "complicated order," if complication consists in having a ready means of adjustment of focus and extension, simple means of raising or lowering the lens without a screw, and a revolving disc of brass to which the legs are attached having teeth round its edge, gearing with a wheel and pinion attached to a folding key to revolve the camera right or left on the stand—certainly not of a more complex nature than an ordinary rack and pinion, as used in the lens mounts.

The camera referred to as having the parallel bellows has a new form of front, perhaps this was too complex! This front consists of two circular revolving panels, one fitted eccentric in the other, no adjusting screws—simply turn one or both panels right or left and the centre of the lens can be brought opposite any part of a 12 × 10 plate (this being the size of the camera shown) from the centre to within three inches of either side, bottom or top, of the camera front, and this without any projecting parts.

There are also a few spring catches to keep the hooks safely in position when the camera is folded which could certainly be dispensed with, and if accidentally broken would not render the camera useless. Or maybe the "complication" consists in the addition of a moveable nut to the endless screw, which enables the camera to be extended to its utmost limit—twenty-four inches—without turning the winch handle at all; but, nevertheless, the screw is there, and the focussing can be done in the old way. Perhaps, however, it is the mode of obtaining the swing to the back which struck the Judges as being complicated, only one screw at each side to loosen slightly, pull back or push forward the back, tighten the screws, and it is done.

Mr. Editor, can you inform me who these Judges were? I may have overlooked their names, but could not find an announcement in either their catalogue or schedule. I suppose I must humbly bow to their judgment. I may also add that these "complicated" instruments may now be seen at the Photographic Exhibition, Pall Mall, London, where I hope your reporter will inspect them when he visits that show. I have had two constructed on the same principle myself in use for quarter-plate size, and also for 18 × 15 inches, and this latter size I am able to manage to use entirely without assistance.

The novelties (if any) in these instruments are protected by two applications for patents, which I have no doubt you will notice in due course.—I am, yours, &c.,

WILLIAM SCORER.

North-street, Havant.

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.—Professor Edmund J. Mills, D.Sc., F.R.S., will deliver a course of lectures on *Photography* on Monday evenings, commencing on Monday, October 7, in "Young" Laboratory-buildings, 60, John-street, Glasgow.

PHOTOGRAPHIC SOCIETY OF INDIA.—EXHIBITION.—In reply to numerous inquiries, the above Exhibition opens in Calcutta on December 1. There is no charge for space. Mounting is compulsory. Framing is optional, but is strongly advised. Framed pictures secure best positions. The Committee will undertake to have glass put in frames if requested to do so; the cost will be about 4d. per square foot. The amount can be sent in postage stamps.

Exchange Column.

I will exchange 12x10 camera and single slide, studio table, and lamp for photographing at night, for Safety bicycle; also boat, oar, and water-piece, rustic bridge, and forty-five 2s. parts of Virtue's Imperial Shakespeare, for interior backgrounds and other accessories.—Address, F. C. D. Huan, Photographer, Shepton Mallet.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

H. B. HARE.—Thanks.

LUCERNE.—Do not alter the lens; it will act well enough in its present form.

G. W. MILLS.—Several good formulae for negative varnishes are given in the ALMANAC for the current year.

SNOW.—The Photographic Society's Exhibition is held at 5A, Pall Mall East. It will be open for some weeks.

C. CLARK.—Messrs. Sprague's process is kept as a trade secret. For the information you require, write to them.

A. C. B.—Try the use of a harder gelatine, such as that of Heinrich. This will, doubtless, get you out of your difficulty.

ASPIRANT.—The only suggestion we can make is that you advertise your requirements, whether you desire a situation or to do work at home.

C. J. W.—The defect round the margin of the negatives is due to the plates. Evidently they have been made a long time. Old plates frequently have this defect.

G. J. J.—From what can be judged from the prints, it would appear that the spots are due to something being splashed upon the negatives after they were finished rather than defects in the plates themselves.

R. B. B.—1. Of all the lenses you have the one best adapted for enlarging from half-plate negatives is the ten-inch focus "rapid."—2. The surface of the paper is very much a matter of taste, but, for anything but the smallest work, we prefer the rough.

WAVERLY.—We cannot give an opinion as to whether the patent in question is a valid one or not. A great number taken out in connexion with photography, probably (as you suggest), are not, if they were contested. You had better consult an expert in patent law before infringing.

A. B. C.—In taking a building of the nature described, tilt the camera to the extent necessary to get it all in, taking care that the back is swung so as to be quite vertical, and that the lens is raised so that its axis shall be on the centre, or nearly so, of the plate. A small stop will then ensure sharpness.

PUZZLED.—There is no remedy now. If the negatives are so much under-exposed as you say, nothing can be done but to take fresh. The only remedy in the case of under-exposure is in the development, and, of course, there is a limit in this; but after the negative is fixed no more detail can be got out.

"49."—It is purely a legal matter. Either you ought to receive the goods or the P. O. O. should be returned. The firm, however, is a highly respectable one, and we think there must be some oversight or mistake in the matter. You might write again, and if no attention is paid, then you might place the matter in the hands of your solicitor. Thank you for the promised contribution.

A. McKAY says he has a wide-angle single landscape lens, and inquires if there is any means by which he can make it take pictures on the same size plate but including a narrower angle.—The focus of the lens may be lengthened by the addition of a negative lens; but unless our correspondent has some optical knowledge he will find it much cheaper to purchase another lens of longer focus.

CHAS. LAWSON.—The only treatise on ceramic or burnt-in photography in the English language of which we are aware, is a collection of practical receipts and hints, compiled at considerable expense by J. Solomon, and now to be obtained (price 5s. we believe) from Mrs. Abenheim, 341, Camden-road, London, N. So far as we have tested them the instructions there given are quite reliable.

W. A. BOROUGHS asks if a gas calorifier is sufficient to keep a studio about twenty-five feet long by twelve feet wide nicely warmed during the winter months.—We are unable to say for certain, but we should not expect it would do so during cold weather. We should ourselves prefer to have one or other of the "slow combustion stoves," of which there are several different forms now in the market. Some of them are very ornamental.

DETECTOR says: "Would you kindly say if I may take a detective camera to the Paris Exhibition? I believe you gave some information on the subject in the JOURNAL, but cannot find out if I am breaking the law by taking it in the Exhibition. Of course I may carry it in the streets of Paris."—Photographs are allowed to be taken in the Exhibition during certain hours, and then only on payment of certain fees. If any one is found taking photographs surreptitiously they subject themselves to a fine and a forfeiture of the apparatus.

C., writing on Carbutt's films, says: "I regret that my experience of Carbutt's films goes to confirm what your correspondent 'L. M.' complains of. The whole of the first packet I tried were useless from transparent markings and sundry kinds of spots. And since that it has been quite the exception to find a film free from marks and spots. It is very disappointing, for in point of rapidity and density the films are admirable, and in point of convenience, both in developing, &c., and in storing, they beat all the film and paper negatives that I have tried.

W. SELLERS complains that in making a solution of white shellac in methylated spirit the whole of the gum will not dissolve, or, rather, he cannot get a clear solution. After standing for several days the top part of the solution gets clear, but when this is decanted the addition of more spirit will not dissolve the sediment. He asks how to proceed.—The whole of the shellac is not soluble in spirit, and what is not is of no use in the varnish, even if it were. Moreover, the bleached lac of commerce always contains extraneous matters besides. The sediment may be filtered out. When this is done very little loss is entailed.

R. H. T. writes as follows: "I have formed the opinion that the colour of a negative has a great deal to do with the resulting colour of the print, from the following experience. Will you kindly say whether I am right, and whether the different colouration occurs from the intercepting of certain rays of light by the yellow varnish? I have a negative the foreground of which prints much too dark, and I have been in the habit of covering the foreground (when sufficiently printed) with a mask; but I thought I would save trouble by coating it with a varnish coloured by the addition of iodine. Having covered the foreground with the varnish, I find that it prints to the proper depth, but while the mid-distance or uncovered part tones brown the foreground tones purple; in fact, the picture looks as if done from different negatives, and on different samples of paper, or at different times."—Printing through coloured media has a marked effect on the result. This may be exemplified by taking a piece of sensitive paper and printing part of it to a certain depth in an unobstructed bright light, then printing other portions to the same depth through coloured glass or paper, which will retard the printing, or in an unobstructed feeble light, and it will be noticed that there is a great difference in the colour. We have often treated on this subject.

GLOCK writes: "Will you kindly reply to the following query in your next issue, if possible? I purchased a quarter-plate camera a short time ago, having been advised to select that size in preference to 5x4, or half-plate, because of its portability and the ease with which negatives could be enlarged, when desired, from the quarter-plate size, thereby avoiding the weight of the larger sizes; now, however, I am told that I was wrong in buying such a small size, and that 'enlargements' can always be told as such, and the results are not to be compared to large 'direct' pictures, &c. Now, I shall be glad if you will just set me right on this point. I may mention that I do not want lantern slides, therefore they need not be taken into consideration in answering the following question, viz.:—To what size can a good average quarter-plate negative be enlarged so that the prints from such enlarged negatives show no falling-off in any way with respect to sharpness, detail, &c.?"—Enlargements from small negatives may be produced very good indeed, but usually they can easily be distinguished from direct pictures, unless very skillfully made. The degree of amplification a negative will bear depends entirely upon its quality and sharpness. A good and sharp negative will bear an enlargement of three or four diameters without very material loss in quality.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday next, October 10, 1889.—First lantern night of the season. Visitors are invited.

HACKNEY PHOTOGRAPHIC SOCIETY.—October 10: A paper will be read by Mr. J. Hubert on *Bromide Enlarging*, with demonstrations. October 24: Lantern night.—*India*, by Mr. Freshwater.

KEIGHLEY PHOTOGRAPHIC EXHIBITION.—An Exhibition will be held in the Mechanics' Institute, Keighley. The Exhibition will continue from Monday, January 6, to Saturday, January 18, 1890, and will include both amateur and professional work. Silver and bronze medals and certificates will be awarded.

We have received a circular letter from Mr. H. P. Robinson, in which he withdraws a statement made in the latest edition of his work, *Picture Making by Photography*, to the effect that Dr. Emerson's work on *Naturalistic Photography* has been almost universally condemned by photographers and the photographic press.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—At the next meeting, Tuesday, the 8th instant, in Mosley-street Café, Newcastle, there will be an exhibition of one hundred and fifty slides by optical lantern of those sent in to the competition. The remainder (one hundred and fifty) will be shown publicly at the Lecture Hall.

CAMERA CLUB NOTICES.—Thursday, October 3, eight p.m.—Opening of fourth One-man Exhibition at the Club; pictures by Mr. H. P. Robinson. Monday, October 7, half-past eight p.m.—First smoking concert of the season. Thursday, October 10, eight p.m.—First technical meeting of the season: Mr. W. Ashbury Greene will read a paper on *Detective Cameras*; members are requested to bring apparatus; a show of cameras will be arranged. Thursday, October 17, eight p.m.—Description and demonstration by Mr. Lionel Clark of his platinum toning process. Thursday, October 24, eight p.m.—Lantern evening: members are requested to inform the Secretaries if they can bring slides. Thursday, October 31, eight p.m.—Discussion on *Eikonogen*, to be opened by Mr. H. M. Elder, M.A. Monday, November 4, half-past eight p.m.—Smoking concert: offers of assistance requested. Thursday, November 7, eight p.m.—Mr. Andrew Pringle will read a paper, entitled *One Hundred and Thirty Exposures*; the paper will be illustrated by examples.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1536. VOL. XXXVI.—OCTOBER 11, 1889.

UNWASHED COLLODION EMULSION.

To many it may, perhaps, appear a retrograde motion to revert to the use of an unwashed emulsion, or one which necessitates the washing of each individual plate after coating, instead of, as in the case of a washed emulsion, merely pouring the emulsion on to glass and allowing it to dry spontaneously. Similarly, there are, no doubt, many who would consider coating plates not at all a step back from the general practice of the present day of buying them ready for use; yet there are not a few who, from inclination or for motives of convenience, still prepare their own plates on special occasions. In like manner, there are, perhaps, some of our readers who, despite the fact of collodion emulsion being a commercial article, prefer to make it themselves, and to such we wish to point out some of the advantages of an unwashed over a washed emulsion.

There is no disputing the general superiority of the latter form of emulsion for ordinary purposes—whether negative or transparency. Treated, as it is, in bulk for the highest degree of sensitiveness and the total removal of all useless soluble matters, the acme of convenience is attained conjoined to keeping qualities, which, perhaps, excel those of the dried films themselves. We have used washed collodion emulsion seven or eight years old that has given at that age the most perfect results, but we should scarcely care to pin our faith on collodion plates of any kind that had been kept so long. In use, too, the trouble of preparation is reduced to the one operation of coating the glass, which is then transferred to a plate box or drying box to dry spontaneously, which, owing to the volatility of the solvents employed, and the almost or, it may be, total absence of water, it does quickly and with the utmost regularity.

With the unwashed emulsion, on the other hand, containing as it does an excess either of soluble bromide or of silver nitrate—for it is practically impossible to exactly hit the balance—together with the "decomposition products" or alkaline nitrates formed in sensitising, as well as a considerable proportion of water, each plate after coating must be carefully washed to free the film from foreign matter and give it a homogeneous character. It is then usually, though this is not always necessary, immersed in a "preservative" or "organifying" solution, the chief use of which is to fill up the pores of the collodion with a soluble substance that prevents its drying or shrinking into an impervious skin into which the developer cannot penetrate. With some kinds of pyroxyline, however, the film retains, after drying, a sufficient degree of porosity to render the preservative useless, and in the case of a washed emulsion the treatment it undergoes in the washing process brings it to that condition. Finally, the plates have to be dried, and this is either a lengthy

operation if allowed to proceed spontaneously, or requires care and special appliances if heat be employed in order to avoid unequal drying, any check in the progress of the dessication resulting in an unsightly drying mark.

This, of course, renders the preparation of the plates a more or less troublesome operation, at least in comparison with the simpler process of purchase, though infinitely simpler and involving the expenditure of far less time than the older bath processes, of which the description recently given of Dr. Hill Norris's "new rapid" collodion process is a fair sample. Yet there are circumstances under which we should unhesitatingly adopt the unwashed emulsion ourselves and recommend it to others.

In the first place, it is much easier to prepare. This statement is true in more ways than one, for not only is the operation of washing, as well as the expense of a double quantity of solvents saved, but almost any ordinarily good sample of pyroxyline will answer, which is far from being the case with washed emulsion. The latter requires a pyroxyline of a peculiar character to withstand the washing process, and such specimens are not infrequently, though perfectly suitable for negative work, unfit for transparencies, especially for the lantern, on account of a faint opalescence or want of transparency when dried. This, though an improvement rather than a detriment to a negative, is decidedly out of place in the glass positive, and here the unwashed emulsion has the advantage.

Next, an unwashed emulsion, if properly made, whether it contains free soluble bromide or free silver, is in a better condition to take density *with ease* than is the case, except under most favourable conditions, after the emulsion has been washed. We do not wish to infer that washed emulsion will not intensify, or even that it is at all difficult to do so, but, as compared with the unwashed, it requires a stronger development, or, in other words, more forcing, which interferes with the delicacy of gradation and transparency, or "juiciness" as it has been termed, of the image. We have, therefore, an easier method of preparing the emulsion to produce a result at least as good, though necessitating a little more trouble in the subsequent operation; and we think that the conscientious photographer, whether amateur or professional, who looks first to the quality of his work, will scarcely begrudge that extra trouble.

On the score of keeping qualities it can scarcely, perhaps, be said that an unwashed emulsion can compete with a washed preparation. Mention has just been made of an emulsion containing excess of silver nitrate, that is, an excess of that salt over and above the quantity required to convert the whole of

the alkaline bromides into bromide of silver. In this condition, as all old emulsion workers are aware, the preparation retains its working qualities for but a short time, a period, indeed, which may be measured by hours, though while in that state it possesses a very high degree of sensitiveness, which gradually gives place to fog, and the emulsion becomes useless. When, however, the soluble bromides are in excess, the keeping properties of the emulsion are greatly improved, and when carefully compounded we have kept an unwashed emulsion in perfect working condition for many months. It is, however, inferior in sensitiveness to that prepared with and used while still containing free silver, and unless very thoroughly washed to remove the effects of the free bromide, or subjected to the action of an "accelerating solution," it falls short of the rapidity of a washed emulsion prepared after the same formula. Still, want of sensitiveness need not be one of the faults in practice.

It is little more trouble to prepare a large batch of emulsion than a small one; indeed, in some respects it is perhaps easier, since there is less liability to error in the matter of quantities. If, then, a quantity be prepared containing a moderate excess of bromide, say two or even three grains to each ounce over the theoretical quantity, the preparation may be relied upon to keep its good qualities for a very considerable time; indeed, it will actually go on improving for a portion of the period. With that excess of bromide the films will be very slow, though not too slow for contact printing, but will give results of the very finest quality, combining the utmost delicacy of gradation with any desired density or vigour and great richness of tone.

If for the purposes of reproduction in the camera greater rapidity should be desirable, it is only necessary to add to a given quantity of emulsion, an hour or two before using, sufficient silver nitrate (dissolved in a small quantity of alcohol) to partially or wholly convert the excess of bromide; or the requisite quantity of silver nitrate reduced to fine powder may be introduced from ten to fifteen hours previous to use, and the emulsion frequently shaken during the interval and carefully filtered before use. An emulsion so accelerated or resensitised will, if used within a few hours—*i.e.*, if coated and *washed* within a few hours—give the same quality of image with greatly enhanced rapidity; but if the whole of the bromide has been coated, it soon commences to become foggy, and eventually quite useless.

Before this stage is reached, if any of the emulsion remain after coating the plates required, it is only necessary to add to it a given quantity of the original emulsion, sufficient to restore the condition of free bromide; the mixture will then regain its keeping powers, and if used in that state will be more rapid than the original; or if the higher degree of sensitiveness be again required, it merely requires the addition of sufficient silver to convert the free bromide in the added portion of emulsion. Many of the old collodion emulsion workers were in the habit constantly of working in this manner, claiming that they thereby obtained better quality as well as greater sensitiveness.

Another method of acceleration which is simpler, though not giving the same rapidity, consists in treating the film, after thorough washing, with an accelerating solution consisting of glycerine, albumen, or gelatine, together with a small quantity of alkali. A weak alkaline wash alone suffices to give the extra rapidity; but the use of a viscous material as well is often convenient, especially in hot weather, in preventing the plate drying unevenly. This plan obviates the trouble of resensitising with silver nitrate and the subsequent desensitising.

So far we have assumed that the object is to prepare *dry* plates for storing or for contact printing; but the films may be used with equal facility in the moist state, and this may often be the more convenient plan. For instance, if a number of transparencies are to be made right away, there is scarcely any necessity to waste time in drying the plates; the operations of preparation may go on concurrently with those of exposure and development, one plate being left to undergo its necessary washing while another is being exposed; or, better still, the required number of plates may be coated and placed in one of the convenient washing troughs to soak. A dozen plates of small size may be easily coated in ten minutes, and no harm will accrue from prolonged soaking, so a stock of films ready for use, as required, may be prepared in a short time and with a minimum of trouble.

A word as to the use of these wet plates in ordinary *dry* plate slides. If introduced into the slide directly after leaving the washing trough, the lower rebate of the slide and the adjacent shutter groove will soon become saturated with water to the detriment both of slide and plates; but if before insertion in the slide the plate be reared up to drain on blotting paper for a few minutes, it will become surface dry, and in that condition do no injury at all. In hot weather the glycerine, or other viscous preservative, proves useful at this stage, as it prevents the plate drying at the edges.

If carefully drained as directed, the moist plate may be used for contact printing, strips of paper being inserted between the edges of the negative and plate. We have frequently thus produced lantern slides, interposing the ordinary mask to prevent contact between the two surfaces, without any apparent loss of sharpness.

Other applications of the unwashed emulsion will suggest themselves as occasion arises; but we have said enough to indicate that it is not an altogether obsolete preparation. It is essential however, both for keeping properties and for the proper attainment of the combination of quality with rapidity, that the emulsion contains a considerable excess of bromide. Keeping quality for a limited period can be secured with an emulsion in which the balance is only just on the side of the bromide; but the quality of image rapidly falls off. In addition to that, the subsequent addition of silver nitrate fails to give either the same accession of sensitiveness or the same good quality as when more bromide is present. For this and other reasons the accelerating method with silver is inapplicable to a washed emulsion.

NEGLECTED PROCESSES.—THE EBURNEUM PROCESS

THE "Eburneum" is, no doubt, a process of which many of the younger readers have never heard, and one that many of the older readers have almost forgotten. Why this process has to be classed amongst neglected processes is somewhat extraordinary, seeing that eburneum pictures are exceedingly beautiful, inasmuch as they possess a delicacy which it is impossible to obtain on paper. They were not difficult to produce, and they are still easier to do now, by more modern methods, than they formerly were. Hence it is possible that they may still come into fashion. As the name implies, the pictures partake of an ivory character; in fact, they were photographs, principally portraits, on an artificial ivory.

The process was first introduced by the late Mr. J. M. Burgess, of Norwich, somewhere about five-and-twenty years ago. It was, we believe, the original intention of its inventor

to sell the process to a certain number of subscribers as a secret process; but before the number was obtained the secret leaked out, was published, and so became public property. The process was, however, practised but to a limited extent by any but the inventor himself, though the results produced by him were universally admired; notwithstanding this it soon fell into oblivion.

The process, as worked by Mr. Burgess, was this:—A transparency by the wet collodion process was produced on glass, the plate, prior to coating with the collodion, being treated with wax to facilitate the subsequent removal of the film. In the development the image had to be kept exceedingly thin, while, as a matter of course, all the detail had to be secured. As a rule the pictures were vignettéd portraits. After the picture, or, rather, pictures—for in practice several were usually made on the same plate to save trouble—were developed, fixed, and finished as transparencies, the plate was placed on a levelling stand, and the eburneum compound poured on. This consisted of a solution of gelatine, with which was incorporated a white pigment—oxide of zinc being the one recommended by the inventor. To this mixture a small proportion of glycerine was also added, so as to prevent the gelatine becoming brittle when dry, and to secure flexibility. Sufficient of the compound was applied to the levelled plate to form, when dry, about the thickness of a thin mounting card. After the gelatine had set, the plate was reared up and allowed to dry spontaneously. When dry, the pictures were stripped from the glass and trimmed. They were then finished.

These pictures, when skilfully made, had all the appearance of being on ivory, such as that used by miniature painters, but without the objectionable grain. Of course, the eburneum compound could be made of any tint by the addition of suitable pigments. It could also be perfumed, as it was sometimes, by the addition of a small quantity of an essential oil to the mixture while in the fluid condition. By a proper proportioning of the pigment to the gelatine the pictures could be as well seen as transparencies as by reflected light. Some photographers who essayed Mr. Burgess' process totally failed through not getting the transparencies thin enough in the first instance, and of too cold a colour, these conditions being quite fatal to satisfactory results. A very thin image, but full of detail and of a somewhat warm tone, is an essential for a successful eburneum picture.

About fifteen years ago, Mr. E. W. Foxlee applied eburneum in the carbon process, and showed some excellent results at one of the meetings of the late South London Photographic Society. In this case the carbon print was developed on collodionised glass, as in the chromotype process. Then, instead of transfer paper, the eburneum mixture was applied in the same manner as in the collodion process of Burgess. But somehow or other the process, so far as we are aware, was never practised commercially, notwithstanding the beauty of the results it yielded.

On more than one occasion we have advocated the employment of "ivory," which may be had at most fancy stationers, in the carbon process. This material is certainly more convenient to use than the liquid eburneum, for it only requires to be softened in cold water and then squeezed on to the picture, to which it becomes firmly adherent when dry. Photographs on the commercial ivory, however, are not so satisfactory as those on the eburneum, as they possess a far less ivory-like appearance. Still, there is no reason why eburneum should not be supplied in sheets like ivory. If a demand were

created for the material, a supply would soon be forthcoming, as it is easy to prepare.

The Eastman transferotype paper affords an excellent method of producing eburneum pictures of a high class. This method of making them would certainly commend itself to every one familiar with the working of bromide paper or the stripping films. The print is exposed in the ordinary way, but to obtain a warm tone a very full exposure should be given and the image brought out with a much diluted iron developer, keeping it somewhat thin, yet securing full detail. The picture is then transferred to a collodionised glass plate, which has previously been talced, precisely in the same manner as when transferring a stripping film negative. The plate is then levelled, and the fluid eburneum poured on and allowed to set, and afterwards dry. When the picture is then stripped off it is finished; or, in the case of sheet eburneum or ivory, it is simply softened in cold water and squeezed upon the glass in the same manner as the gelatine skin is treated in the stripping film process for negatives.

Opalescent celluloid films coated with bromide emulsion are now being introduced commercially, and they may prove a ready means of producing eburneum pictures. But the examples we have hitherto seen by this method have been too cold in tone, and much too opaque and heavy; hence, they lack the transparency in the shadows which is so essential to perfection. These shortcomings in the specimens brought under our notice appeared to be due rather to the development than to the method itself.

With the later methods of production just alluded to there may yet be a future for pictures on an artificial ivory similar in effect to those by the late Mr. Burgess' process.

THE paper on a *New Photographic Developer*, read by Professor Liveing before Section B of the recent British Association meeting, forms a scientific account of the new substance comparatively recently introduced into commerce under the name of eikonogen. It has been objected that this is a mere trade term—a "fancy name" in fact (we are not aware that it has been protected under the Trades Marks Act), but it is quite evident that its chemical synonym would never be used in ordinary parlance. It is an acid, and is correctly termed: Amidob-naphthol-B-sulphuric acid, its formula being $C_{10}H_5, NH_2, OH, SO_2H$, and was first described by Professor Meldola in 1881. Professor Liveing's paper is interesting, more particularly as being a compact chemical account of the new agent, for he states that his own experience with it is very limited. He has found it, however, to give, in his spectroscopic work, which alone is the department wherein he uses photography, a picture in which the lines are blacker and more easily seen under a microscope than when pyro is used.

WE recently described a new method of folding and using a filter paper so as to present the largest surface to the liquid, as described in the *Chemical News*, and in the current number an improvement upon it, in the shape of a novel support, is explained by Mr. C. R. Gyzander. As a support of platinum wire is not likely to be used by photographers, it will suffice to describe the shape in which glass rod or tube is used. The rod is bent first into the shape of a capital letter M, the loop reaching to the base of the letter. The left hand upright is then bent half way up and brought round to the front in the form of a semicircle, and the right leg similarly treated, but turned behind the loop, the two loops forming the support for the paper, and the loop serving to separate the two inner folds of the filter. When in operation, and used apart from a funnel, the liquid drops from the lower part of the rod, or when larger papers are employed they can be placed in a funnel upon this support and filter much

more quickly than under ordinary conditions, though less so than when the funnel is not employed.

THE process of determining the strength of silver solutions by means of a solution of chloride of sodium is so well known and sufficiently exact for all practical purposes, that we merely place on record a new method, capable of great accuracy, recently described by M. Adolphe Carnot in *Comptes Rendus*. It is based on the insolubility of silver iodide in a nitric solution, provided it contains no alkaline iodide. One hundred centimetres of silver solution is taken, and if the approximate strength is known, a sufficient quantity of decinormal solution of iodide of potassium is added, and the whole briskly stirred so as to obtain the precipitated iodide in dense clots. The liquid is decanted along with a little washing water in a beaker, and a small quantity of starch paste and about ten c.c. of nitric acid, slightly discoloured by age or exposure to light, added. If at this moment the liquid becomes blue, it is exactly decolourised by means of a standard (centinormal) solution of silver nitrate (1.7 gramme per litre). If it is not coloured blue, potassium iodide solution is poured in till the permanent blue tint appears, which is then removed again by the standard silver solution. The author states that he has by these means been able to obtain results accurate to the fifth or tenth of a milligramme.

SOME experiments by Herr C. Winkler show the difficulty of obtaining pure salts of so easily treated a metal as gold, and throw a further light on the ease with which some simple every-day reactions can be shown really to depend less on the principal agent than on the presence of impurity or foreign matter. Thus, most of our readers are aware that the destructive gas chlorine is, in most cases, quite inert, unless moisture be present; and many other equally cogent examples could easily be cited. Taking gold for example, Herr Winkler's results show how ordinary methods can be falsified. He precipitated some gold in solution by means of sulphurous acid, and then washed and dried it at 180° C., and subjected it at 140° to the action of chlorine that had been repeatedly washed with carbonate of soda solution and dried with potash. He then dissolved the desiccated salt in water, and heated it for a long time on a water bath and filtered the solution. When this solution was treated gradually with sulphurous acid no precipitation was produced, even after boiling or exposure to air; only a deep red colouration was to be seen. He believed the colour to be due to the presence of minute quantities of aurous chloride.

AGAIN, he treated purified gold suspended in water with pure chlorine in the absence of light and dust particles, evaporated the solution to dryness, dissolved the residue in water, and filtered. There was no aurous chloride here, and when diluted there was, in place of precipitate or the above-described red colouration, a green colouration. A pure salt of chloride of gold and sodium can be obtained by adding pure chloride of sodium to either of the above-described gold salts and heating for some time. The red colouration is given by the pure salt, the proportion of gold in which is put down as being 54.39 per cent. It will be seen thus that the makers of the commercial chloride of gold do not wander far away from the actual theoretical equivalent, their proportion being seven in fifteen, or between forty-six and forty-seven per cent.

ON THINGS IN GENERAL.

"THE steady advance of the photographic art—for art indeed it has come to be," a sentence which forms the opening of the *critique* on the Exhibition in Pall Mall by one of the London dailies, strikes the keynote which governs most of the recent reviews on matters photographic; and, after the supercilious way in which "mere photographs" were wont to be treated no long time ago, it is refreshing enough to read. Another paper puts the matter in a nutshell. "Time was when art and photography were considered as the poles asunder. . . . But the hostility of photography and art is in a higher sense than this a thing of the past. Good photography is now artistic or it is nothing. . . . What is demanded now is that the man behind the camera shall have the instincts of the artist. . . . in fact, lenses, dry

plates, and instruments are now tools in the hand of the artist as completely as the brush and chisel." I rubbed my eyes when I read this in the columns of a leading evening paper, for it represents to a nicety what I have always claimed—it is not the product of process and tools that makes a work of art; otherwise, the meanest sign painter produces works of art: it is the extent to which the result embodies the art knowledge of the producer. Who can deny this? and granted so much, who can deny photography the possession of such power? A limited potency, it is true; but, nevertheless, actual and existent. I would not have my readers imagine that I believe the improvement visible in the *technique* of photograph producing to be necessarily a sign of artistic improvement—quite the reverse; but there is abundant evidence now to be seen of a spread of that feeling for beauty, that power of bringing before the spectator some high thought, some conception, be it great or simple, that first found place in the brain of the producer, and all combined with greater power of expression. Rejlander never saw such perfect photographs as are now daily produced; but, on the other hand, no photographer, to my thinking, has ever excelled him in the "power of appeal to the feelings"—power of producing work which all who saw would stamp as the product of a mind instinct with art. The day is now quite past when, to slightly alter Dr. Johnson's dictionary upon another matter, the critic will say, "a photographic exhibition is worth seeing, but not worth going to see." I must confess to some little feeling of disappointment in the present Exhibition at the presence of a larger amount than usual of pure rubbish. What were the Hanging Committee about to permit its presence? Why also should they put on the line one of the poorest pictures in the room—an exceedingly flat "carbon" picture of a very conspicuous colour feebly worked upon in crayon, differing most conspicuously in colour from that of the print itself? However, I will not complain; the hanging was very effective decoratively, a point which must be considered, and there were few such conspicuous cases as this.

There were a few life-size heads to give point to Mr. Dallmeyer's dictum recently cavilled at, that "the direct large head, when taken under the most favourable circumstances, that is, with a lens of long focus, is undoubtedly much more pleasing than an enlarged small image." So far as work has been done at present this is all very true; but it is not necessarily a result of either mathematics or lens making, it is a question of process. I strongly believe that the day will come when an enlarged portrait photograph will be executed which shall not be distinguishable from one taken direct, a far more desirable consummation than the ability to make a good negative with a big lens. Given two results of equal merit, commendation should be given to the process which occupies least time and gives least trouble. Life is too short to go up a ladder to ascertain what's o'clock.

But why this eternal rodomontade whenever lenses are mentioned? Why this talk of long focus, and short focus, of conjugate foci, and theoretical and actual truth? Well might Captain Abney make the remarks he did at the British Association upon the want of science among photographers. The whole truth can be put in a line—the existence and extent of this so-called distortion (as a matter of fact there is no distortion) depend not upon the lens, but upon the standpoint, the distance from the object where the lens is placed. In the case of a portrait the difference between rectilinear and portrait lenses is quite a negligible quantity.

In no case in the whole range of photographic practice does the utter and entire absence of scientific—aye, it may even be said "reasonable"—method exhibit its naked ugliness to the extent that is seen in developing formulæ. It is positively nauseating to read the descriptions given of any novelty in this direction. We have already on our hands a new candidate for favour in the new sulphonic acid termed eikonogen, and there were fair grounds for hope that after so much had been said on the subject we might have some principle, some reasonable method of stating proportions in these formulæ; but no! If we want to know what is the difference between A, B, and C's method of working, what strength of "eiko" (will that be its laboratory name?) to the ounce or litre of water, what amount of alkali or bromide in proportion to "eiko," we have to make a calculation wasteful of time and temper, with also the possible result of finding two apparently different formulæ to be almost identical.

Such little vagaries as dissolving sulphite of soda at the rate of a pound to two pints of water one has got to look upon as a necessary concomitant of these formula-mongers, whose practical knowledge is about equal to their acquaintance with scientific method; but at the same time it might be convenient if the Editor were to get a stereotyped footnote, thus: "These proportions are impossible," the objection would be that it would be a serious inroad upon the profits of the JOURNAL. Such formulae and such modes of placing them before the public degrade the science, and render so many of its exponents little more than laughing stocks.

My lucubrations must end this week by a reference to the "new mode" of preventing blisters on albumenised paper. The practical photographer is well aware that though some brands of paper are specially liable to blister, suitable treatment will reduce them to a minimum; but failing any other remedy alcohol is excellent. Not however, as lately recommended, as an intermediate bath between toning and fixing: that would be absurdly costly, even when methylated spirit was employed. The place for the alcohol is in the fixing-bath: from five to twenty per cent., as found desirable, is a certain cure always, which salt is not.

FREE LANCE.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—II.

WE now commence a detailed notice of the many photographs in this year's Exhibition, which are well worth a very close inspection, and as medals have again been awarded for the best work, we will give due honour to those exhibits which the Judges have chosen as worthy of distinction.

Lyddell Sawyer (No. 84), *Dangerous Company*.—Medal.—This is one picture out of ten, all showing great artistic perception of form, and light and dark portions for pictorial purposes; in fact, many of these pictures suggest the idea that they have been photographed from paintings. The particular study to which the medal has been awarded derives its chief interest from the two figures—one a young girl, leaning against a seat attached to a tree in perfect ease, listening to the soft nothings of an admirer, who, partly in a boat and partly reclining on the grassy land, gives the title to the picture, which tells its tale in so pleasing a manner that all who see this photograph will sympathise with the very pretty way in which the everlasting story has been treated. We would call special attention to this picture for the very clever way in which the contrast of light and dark portions have been arranged so as to demand the fixed attention of the beholder. There is one point in this picture which is well worthy of attention, and that is the cleverly arranged bit of drapery which, laying on the grass, and in harmony with the oar of the boat, also laying on the grass, very clearly shows the artistic perception of the right balance in the arrangement of form; in fact, the whole selection and construction of this picture, with its contrast of light and dark, is a most felicitous example of photographic art work. But (and we hesitate whilst we write) why was the brush used on the print? We must be loyal to our scientific method of producing pictures, and, with trepidation, would warn this most promising young artist that the clever photographic delineation of nature must not be jeopardised by the unartistic brush. At another time we will call attention to the remaining very attractive photographs of this promising exhibitor.

R. J. Williams, jun. (Nos. 99 and 101), *Two Photographs*.—No. 99, *Sirripping*, and 101, *Prancing* (medal)—are very clever pictures. The figures, upon which the artistic perception has been, as it were, brought to a focus, are very clever specimens of that section of naturalistic art which consists in the choice of the right moment when the moveable object is in artistic accord with the fixed view of the spot chosen. In these two pictures this capability is most admirably illustrated. These photographs also show a departure from the hitherto very good work of this exhibitor, but who seemed to be tied down to the style of a well-known photographic exponent. These exhibits show an independence of the master which promises well for the student, and are two most admirable specimens of photographic art work, being far removed from those productions of photographic realism, which, in many instances, only give the results of science, without any art. The position of the figures in both pictures show what a powerful effect can be produced, even when the source of light is right in front

of the camera. These pictures remarkably illustrate the way in which photography should be utilised by artistic workers, viz., science portraying truth under the guidance of art.

Frank M. Sutcliffe (Nos. 136, 137, 138).—Medal.—These consist of three specimens of the usual productions which this exhibitor produces every year. They consist of pictures with an artistic perception of arranged or waited-for moments, when the figures combine into what will eventually prove to be a pictorial study. Whilst admitting that there is very great artistic construction shown in these photographs, we feel compelled also to state that some choicer specimens have been shown by this exhibitor—in fact, the work shown last year by Mr. Sutcliffe were remarkably fine examples of this really artistic photographic worker. However, as evincing an exceedingly effective capacity for utilising the picturesque in simple seaside and country-life figures, this photographic art worker keeps up the even tenor of his way, which we venture to suggest is capable of higher possibilities in photographic representations of more emotional scenes.

Green Brothers (No. 178).—Medal.—Here we come upon the debatable ground of enlarged work; by that we mean that the subject matter always being the same, or rather remaining in the same place or position, the final result will depend entirely upon the scientific capabilities of the operator to produce a negative or enlargement which shall contain the best record of the light and shade, and more especially detail, of the original negative. We cannot but express the notion that however successful or satisfactory such representations may be, photography does not do full justice to the scene portrayed, the chief interest artistically felt being in the colour, which a simple translation into black and white does not always realise. There may have been a larger amount of transparency in the water, which would have assisted the picture in its photographic rendering. The left side of this print appears somewhat coarse in detail, almost suggesting that the scientific lens was at fault on this side of the negative.

Ralph W. Robinson (Nos. 413 to 426, 439 to 441, and 457 to 479), *Portraits of some of the Royal Academicians and Associates*.—Medal.—We have here a very interesting collection of thirty-one whole-plate photographs of the celebrities of the Royal Academy of Art. Such an assemblage of the acknowledged aristocracy of fine art has never before been subjected to the comparatively lower grade of photographic representation, and very much interest will arise from a careful study of these very successful portraits, which derive great interest from their freedom of subjection of the usual photographic studio, being taken at the homes of the sitters. There is here no apparent posing for effect, and the whole series very forcibly bring to mind some remembrances of the Dutch school of portraiture, where the home surroundings of each portrait give an assurance of the personality and truthfulness of the sitter's every-day life. We arrive at the conclusion that the individuality of each sitter is very marked, consequently there is a peculiar charm and interest about these portraits, which not only reflect much praise upon the son of an accepted master of our art science, but also makes us familiar, in a very natural way, with the individualism of certain eminent men who have thus been brought into direct contact with the outer world. There are two matters which suggest themselves from a perusal of these very clever and promising photographs: one is, that such eminent exponents of fine art should have acknowledged the present position and capabilities of photographic portraiture by submitting to the possibilities and contingencies of our scientific art; the other, that naturalism by itself is not capable of expressing pictorial ideas, but must be subjected to the higher force of design and artistic control. It is very evident, from a study of this very successful series of portraits, that much thought and artistic usage of material has been given to these portrait studies.

Harry Tolley (No. 447), *Carting Hay*.—Medal.—This exhibitor, from whom we naturally look every succeeding year for some refined and artistic studies, has not disappointed us. This picture is very simple in its origin, but notice what thought and artistic perception has been brought to bear upon the accessories introduced, viz., the waggon full of hay, the horses, and the men, all these, possessing various gradations of tone, ranging from black to pure white, have been so arranged as to form a very artistic result. Notice the figure which has been arranged to lay down on the hay, just in front of the

foremost horse, thus carrying out the dominant idea, which must have been instinctively felt, that the whole outline of distant hills, the cart of hay, the horses, and this reclining figure, all tended towards a line in perspective. This result evinces design on the part of the photographer, and which, unknown to the general observer, conveys the sensation of a pleasant picture, and with nothing artistically objectionable in it. This is one of the year's exhibits which so much raises the possibilities and realisation of photographic art.

Robert Faulkner (No. 480), *Professor Stewart Blackie*.—Medal.—A most artistic and effective study of a difficult subject, placing the photographer in one of the most trying and momentous positions to which he can be placed, that is, the rendering of the intellectual attributes of a sitter by the agency of a mechanical instrument which automatically obeys his will, so that it is just the thoughts and intentions of the operator which we see before us, as well as the purely scientific aspect. Therefore, in this study we recognise the outcome of thought artistically shown in the arrangement of the position; then the right moment to appreciate the individuality of the model; and, finally, the precise moment of time when science obeys the dictum of art. This portrait, in all respects, deserves the most thoughtful attention of all who desire to raise photography to the position of something far above its ordinary mechanical efforts.

APPARATUS.

In the Apparatus Section and on the tables are a good display of many of the mechanical appliances which have been introduced during the past year.

The detective camera invented by Messrs. Swinden & Earps, for which a medal was awarded, differs in many respects from any others of the same class hitherto introduced. In this the plates, about twenty in number, are simply backed with ruby or other opaque paper and placed in a reservoir at the back. They are kept pressed forward against the exposing plane by springs, and after the foremost of the series has been exposed, it is, by means of a handle or plunger below, allowed to drop into a recess in the bottom, in which it lies face down, the second plate falling in turn upon it, and so on until the whole have been transferred from the back reservoir to that below. The opaque paper backing overlaps the face of the plate slightly, and thus achieves the twofold purpose of preventing the transmission of light from one plate to that behind it, and of protecting the sensitive surface from abrasion. When all the plates have been exposed they are removed from the lower reservoir through a door in the side, and the now empty back reservoir is recharged. The Photographic Artists' Supply Association, Charterhouse-square, are sole agents for this camera.

There are some very useful appliances connected with the oxy-hydrogen limelight exhibited by Mr. R. R. Beard, these consisting of regulators for compressed gas, which exercise a discriminating power upon the emission of gas from the cylinders. Mr. Beard has supplemented this desideratum by the introduction of his gas connector for two different-sized necks of cylinders, though why there should not be absolute uniformity in the screws of all cylinders we are at a loss to perceive. Anyhow, the connector is useful.

Mr. Thomas Samuels shows a variety of apparatus comprising his "Model" 5x4 detective camera fitted with interchangeable case, a tourist's portable hand camera for half-plates or films, a studio camera with focussing cloth always in position, and a changing back for a hand camera.

The "Al Fresco" enlarging camera of Mr. A. R. Wormald, of which we gave an account when describing the apparatus at the Crystal Palace Exhibition, is here to be seen.

(To be continued.)

SOMETHING NEW IN STUDIO CAMERA STANDS.

THE word "new" in the above heading is possibly rather a venture—some term to use in these days, and will tend to raise expectations not easily gratified; nevertheless, I hope to justify its use by adding another idea to the common stock.

The early and still most common form of studio stand—that consisting of the rising pillar and table top with the Archimedean

screw and rackwork as the means of putting it in motion, and also the table stands of both English and American design and manufacture—have all the common fault of deficiency of range, the necessities of their construction not admitting of both sufficient elevation and getting near enough to the floor in the same piece of apparatus. There is a patented form of stand which is not defective in these respects. It does not, however, appear to be so widely known as it merits. Of the two failings, that of not being able to go low enough is the principal, child and animal photography on the floor being practically beyond the operator from this cause alone, unless he use a supplementary floor similar to the one I described and employed in these branches of the art some years ago. Without this the production of the pretty and unaffected pictures of children playing on the ground were not possible, as the views from the high stand had too much of a bird's-eye cast to be pleasing; and besides, standing and many other poses were beyond the powers of quick-acting lenses. The old pattern might be made with less rise now the question of rapidity of exposure is not the prime consideration, and this would enable some modifications to be made whereby the camera could be worked at a lower level. In collodion days it was necessary, to ensure average definition, that the lens should be humoured in every possible way, and that no advantage which the rise and tilt of the stand or the raising of the camera front were capable of giving should be neglected, as attention to these matters meant better pictures with a larger stop.

Many years ago a writer in these pages, in discussing the merits of the studio stand and noting its shortcomings, suggested in remedy that the table carrying the camera might be hung in uprights and counterbalanced by weights on the principle of, and similar to, the hanging of sashes. The idea embodied, and I should imagine to a great extent renders invalid, some of the claims of a recent patent which includes these features. The idea struck me as being of the right sort, and a note of it served for the germ of the modified form about to be described. The system of counterbalancing by weights having many objections, the problem was, How to hang the table in the uprights to secure the advantages of that system, and to have besides a ready means of adjustment to enable cameras of various weights to be employed at will. A tight blind cord solved it. The principle of tension thus illustrated, and capable of being regulated to act between almost any extreme by the simple turn of a screw, gave all that was required for the purpose, and was soon practically applied to a stand with the range of a few inches from the floor to about six feet from it, whose table or support for the camera can in a second or two be adjusted to support one pound or fifty, and so sensitive that slight pressure will place it at any part of the range where it will remain or may be further secured with a bind screw.

I have constructed a couple of stands for large and small cameras respectively, both of which, although of different model, embody the ideas sketched out above. The smaller one to carry a whole plate universal has its foot or lower portion made according to the model of the usual form of Archimedean, but much lower, and of a size sufficient only to give the requisite stability. This, instead of being pierced at the centre with the square hole for the admission of the central pillar, is left intact, but cut away at the sides for the reception of two substantial and deeply grooved uprights of sufficient length for the range decided upon. These, when fixed and cross-tied above, complete the framework to receive the support for the camera. This is of the usual form, and is fitted with the means of tilting and giving lateral motion exactly as its predecessor. Its sides, however, are fitted with two vertical slips to take the grooves of the upright frame, which are pierced with holes on their upper and lower ends for the sash-line fastenings. On the cross-tie are screwed two shank pulleys which, when this is fixed in position, come into the grooves of the uprights and provide the means of suspension. The lower ends of the uprights, where they pass through the lower board or timber of the foot of the stand, are fitted with sliding blocks bearing two similar pulleys and having a screw with wing nut projecting from the bottom end of each. These form the other points round which the cord circulates. Across the bottom of the stand, and extending between the uprights, is a piece of spring steel hung on pivots at the centre of its length, scale-beam fashion, which is pierced at its ends with holes to receive the screws of the pulley blocks where they are retained by their wing nuts.

To complete the arrangement for action, a length of sash line is taken and fastened in the upper hole of the vertical slip on the side of the table, its other end, being passed over the top pulley from the front, is conducted down the groove in the upright to the lower one, round which it passes to the under side of the slip, where it is pushed through the hole and fastened. The other side of the table is suspended in the same manner, and completes it ready for regulating the

tension of the cords to any weight the table top has to support, or to any state of the weather and its effects in expanding or contracting them. This is effected by means of the screws. The nuts are turned up equally, till the cords are strained tight enough to support the table itself. The camera is then placed upon the table, and a few more turns given to either nut till the tension is right for that also. The spring equalises the pull and divides the weight between the cords, and thus ensures the passage of the table and its burden, as it is raised or lowered in the uprights, to be free and smooth, with no liability to stick, as would be the case if no means of automatic adjustment were present. A bind screw on the sliding portion operating a slip to grip the upright destroys any possibility of slipping, and when this is released and the tension is right, a mere touch is all that is needed to carry the camera through the whole extent of its range to within a few inches of the floor to five or six feet above it. This system of tension, the application of which I conceive to be new, possesses many advantages over counterbalancing by weights—the one being capable of adjustment, while the other is a fixed quantity.

The second stand, from being designed for large and heavier cameras, is of a different model, especially in respect of its foot. This consists of two pieces of timber framed together with cross-pieces, and made more solid by another stout cross-piece, in which are stepped the two uprights. These, again, are of a substantial kind, about six feet high, with a cross-head above, and held truly perpendicular to the foot by scrolled pieces used as struts on the sides. Besides this use these scrolls serve the purposes of ornament, and destroy the appearance of nakedness and instability which characterise the uprights when no such supports are applied. On the insides of the uprights are worked two grooves about three-quarters of an inch apart, which are fitted with tongues of mahogany to serve as guides for the table or cabinet support for the camera that is to slide between them. In the main stuff at the top and bottom the pulleys are fitted, the lower ones being arranged to slide as in the preceding stand, and may be either used with counterbalancing weights or tension cords, as may be found most convenient. The sliding support for the camera is made in the form of a small cabinet to contain the etceteras required in the working of the studio camera; its top having all motions—lateral, tilting, and so forth—usually found in well-made stands, and has a bind screw to keep it steady in any desired position.

In a large studio a stand of this kind has a very superior look, both solid and good. Its weight gives it steadiness, while its being fitted with rather large castors enables it to be moved into position as readily as any stand of lighter make. There is none of the grinding business about it of the older forms, as immediately the bind screw is released a slight pressure up or down elevates or lowers the camera into position with the greatest nicety, and without noise or bustle.

JOHN HARNER.

THE WHOLE DUTY OF THE PHOTOGRAPHER.

I.

"*Je n'en vois pas la nécessité, moi !*"

THE French cynic notwithstanding, most men are agreed that they must live, and all whom we call in the least civilised endeavour to do more, and to live well or beautifully. It is said that a human creature may support life in this country on about seven or eight pounds a-year, whereas the support of an agricultural labourer costs between thirty and forty pounds. In so far, then, as the civilised man surpasses the bare necessities of life and acquires luxuries, does he surpass the animal and become an artist, good, bad, or indifferent, according to circumstances; sorrowfully bad, it must be admitted, in most countries, though not in all. The Indian and Japanese, living on rice, and almost without clothes to cover them, are true artists, and have given laws of beauty to the Western world.

The attempt to live well has naturally as many different developments as there are different dispositions of men. Some are content with a sufficiency of whisky, others require fine food, but all agree in demanding the satisfaction of some sense which may be more or less subtly developed. The gratification of the sense of hearing was, no doubt, the origin of music and poetry, and indirectly of all literature. The sense of sight has been similarly served from the earliest times by the production of beauty in colour and form. The photographer is one of the recent products of the world-wide demand for things fair to see, and his highest duty is to satisfy this demand in the best manner possible. This is what might be described as his function with regard to the sensuous side of man; he has many other duties

which I regard as lower, and which serve the intellect. Thus, just as literature has to be degraded to the production of scientific treatises, and all the other "books which are not books," so the crafts of drawing, painting, and photography have to be made available for conveying information to mankind through the eye.

I wish first to treat of what I regard as the duties of the photographer in this lower and less vital sphere of labour. As a photograph easily surpasses any other sort of picture in accuracy and detail of form, so all descriptions of things new to man ought to be, when possible, completed by photographs, and the photographer should be regarded as essential to every exploring party, whether in search of antiquities in Egypt, unknown types of man in Africa or America, new plants or animals or insects anywhere in the world.

In order to gain some idea of what photography may do in this way for us and our descendants, let us look a little into the past to see what it might have done for us if invented at an earlier date. For long enough the so-called historians have occupied themselves with chronicling the doings of kings and princes and the fighting of battles. Even this sort of writer would acknowledge that accurate portraits of his characters would be precious beyond calculation. What would we not give for correct portraits of Edward the First, or Queen Elizabeth, or Shakespeare—who ought to come first? Or here, in the north, would we not give anything we have for portraits of Queen Mary, or Robert Bruce, or Michael Scott? Of Bruce it is true there is a portrait by Blake, but the modern critic is apt to call in question the reality of the spectral appearance from which Blake worked. There is another class of historians who are gradually replacing the devotees of kings and battles with a real story of the progress of human life, and to this class of writer it is hard to say what sort of record would not be valuable. How precious is an old map, even though there are none of great antiquity, and the earlier ones are wildly incorrect! Still they are better than nothing to a generation thirsting for knowledge. A very learned historian (Thorold Rogers) has devoted many years of hard labour to collecting from every imaginable source all evidence bearing on the ways of life of the people of England in olden times. For all his research, the picture of the life of a peasant of the fourteenth century is very incomplete and unsatisfactory. It is possible to show how long he worked, and what was the purchasing power of his wages, and so to prove that his condition was in many respects much better than that of his descendant of the nineteenth century; but as to what sort of house he lived in, what tools he worked with (except that very few of them were made of metal), what clothes he wore, and even what sort of man he was himself, we are and must remain almost wholly ignorant. Any accurate picture of the house and its surroundings, interior and exterior, would convey more to our minds now than all the laboriously compiled figures of the historian or statistician. But this is a small part of the legacy that the imaginary photographer of that day might have left to us could he have existed. Accurate records of progress in every form would now be of enormous value, both to the scientific historian and to the biologist. There is some reason to believe that the average height of the men of our race has increased in the course of centuries, and it is almost certain that the weight of a fat bullock now is about three times what it was in the days of the earliest records; probably the sheep has progressed in the same manner. And this wonderful change is by no means confined to animals. Our food-bearing plants have also developed under the hands of the skilled cultivator. But how? At what rate? Through what stages or processes of change? We know not; but all this and much more might be told us by photographs or accurate pictures of these things as they were and as they are, and Mr. Francis Galton would not require to spend his life in hunting men's memories for statistics of heredity, the field of knowledge would lie open where to choose.

Of the methods of commerce of that old time we are almost as ignorant. We do know that very long journeys were undertaken, that the cost of the carriage of goods was not high, and that by one means or another heavy goods were conveyed, not only through the length and breadth of Britain, but even from the remotest parts of Europe; and that the great periodic markets, like Stourbridge Fair, drew buyers and sellers with their wares from every country in Europe, and even from Arabia, Persia, and India. How these merchants came, what manner of men they were, and even what they brought with them, are questions surpassing the knowledge of the historian. These and many other unsolvable problems might all be matters of common knowledge to us in this day had there been any one who made it his business to produce accurate pictures of the objects and events passing under his notice. All this is very visionary, and the truth is, such a being could not have existed in a non-critical age, when men took things as they found them, with-

* The story is as follows:—*Culpit* (excusing himself for his offences): You see I must live, my lord. *Judge*: For my part, I don't see the necessity.

out comparing, testing, criticising, and considering what will be the effect of such an action? what will posterity think of this?

Times have changed deeply since then, and we now live in an age of increasing criticism and self-examination, whether for good or for evil we cannot say. This change appears to me to warrant the opinion that the time has now come when we may begin consciously and designedly to preserve historic records for the use of posterity. What has posterity done for us? the cynic may ask. I neither know nor care; let it suffice that we have it in our power to do much for posterity, with which any reasonable being may rest satisfied.

Naturally it is not possible for any individual or small group to make and keep records for generation after generation; this is the proper function of large organizations or societies which are immortal. It is not long since a proposal for a Royal Photographic Society was mooted, and though I am not aware that at the moment it attracted much attention, I have no doubt that within the next few years such a body will come into existence; and let us all hope that when it does the F.R.P.S. will not fall into the same evil repute as another four-letter title beginning with F.R., but that it will carry a guarantee of a real scientific knowledge of photography, instead of being a sort of charm or fetish bought for money. Such a Society should keep a library of great albums containing a record as complete as it can be made, and in *permanent photographs only* of the present state of the world. This is not a small task; indeed, to do it completely far surpasses the resources of any one nation, but I hope to see the foundation of a Royal Photographic Society soon followed by a similar organization in every civilised country.

How may such a record be kept? The energy and skill to do it are by no means wanting; the photographer seems to be much more truly ubiquitous than the proverbial Scotchman: he is to be found in balloons, as well as in catacombs, mines, and sewers; he swarms on the glaciers and peaks of the Alps, he eludes the guards of Buddhist temples, he penetrates forests, "where the hand of man has never set its footprint;" I believe he has been at the bottom of the sea—in short, wherever man has penetrated his three-legged friend has not been far behind. This is good, and often very good; but it is not all. To begin with, what do most photographers do with their results? It is much to be regretted that, as a rule, they make a few silver prints, and either keep them, or give them to a few friends, or sell them, as the case may be. I think I can imagine the indignant contempt and fury of the photographer of half a century hence for my brethren of this time, who, having at their choice a multitude of beautiful permanent processes, still obstinately continue to waste their best exertions on the production of pictures which will be nothing but waste paper in a few years. If the results produced in carbon or platinum, or any other permanent material, were in some way repulsive to the sight, this would still be no sufficient excuse for neglecting to produce a certain number of them—not for hanging on walls or for show, but for preservation. The fact, however, is quite the other way; most of the permanent processes yield results of immeasurably higher artistic merit than the common silver print, to which we adhere with such infatuation. Far the most beautiful, as well as the most enduring form of sun picture, is the carbon transfer on opal. Both image and support are in this case everlasting (barring accidents), and yet how rare are such photographs in comparison with trashy prints having the "brilliant surface" so much sought after by the barbarous. Professional photographers are much to blame for the slowness of the introduction of carbon transfers. A professional who is much in fashion at present lately produced an excellent negative of one of my friends, and I wanted a carbon print on opal, single transfer. On inquiring the price of such a thing, cabinet size, I was told 4*l.* 4*s.*, "enlargements dearer according to size." I did without. Now, including all possible expenses, there is no reason why this price should exceed five shillings. Of course, all photographers' charges are not the same, and photographs on opal glass are making their way into the market steadily, whereat all who love things beautiful should rejoice.

All this, however, is hardly relevant to the question of how may the history of the present day be handed down to our descendants in a true and graphic form? In many ways.

Firstly, I should say, by photographing the human beings of this time—not only those who can pay for being taken, but also those who cannot. Of the former class, I take it, pictures enough and to spare are being daily produced, but very little record is being kept of the state and appearance of the poor. The Crofters' Commission excited a passing interest in one class of poor people, and we had a few photographs of Croft houses and their inhabitants in working garb. These will be most valuable documents a century hence, if they are still in existence. Such photographs illustrating social states should be multiplied, which might surely be done easily now by means of one or another of the many detective cameras in the market. Nothing is

surer than that the social relations of classes in this country will change profoundly in the not distant future, and after the change has come about records of the state of matters before will become valuable. Let it be remembered that though the poor are the majority, they are naturally inarticulate and die unrecorded.

A new departure in portrait photography has been made lately in the production of composite photographs. Whether these will ever have much value, except as curiosities, is rather questionable, but I am disposed to believe that they may one day be regarded as valuable as records of types of face. In order that they may serve this end they would require to be done in great numbers, and the prints must be permanent.

All photographs ought to be labelled, for how can any one be expected to remember what they all are, and when and how they were taken? Those which are intended for permanent preservation should be very exactly labelled with date, time, place, and as much as possible of the conditions.

Cosmo I. BURTON.

(To be continued.)

THEORY.

FROM time to time there appears in the photographic journals an elaborate article in support of some particular theory, and, judging by the language in these papers, the inference might reasonably be drawn that photographs were in great part matter of line and rule, or the outcome of equations more or less complex.

It will be familiar to readers of the *St. Louis-Canadian Photographer* that quite recently the theory was promulgated that photographs should be inspected or studied at a distance from the eye of the spectator equal to the focal length of the lens by which they were taken. There are objectives in use with a focal length of three and a half, four, five, or six inches. Will any theorist kindly study a photograph, say, *four* inches from the eye and report the result? This is really bringing the figures of our youth into a prominence which is scarcely to their credit. What can the majority of us see in a picture four inches removed from the organ of vision? and what a wonderful thing this photograph must be, according to the theorists, that it can only be properly studied at a distance from the eye corresponding to the focal length of the lens which projected it. Surely some account ought to be taken of the near-sighted people and the people of long sight. We read the newspaper at arm's length if necessary; a print or a painting we criticise according to its fineness of execution, its breadth of lighting and effect; but a photograph is quite another consideration—out with the pocket-rule or the tape measure and query the focal length of the lens before we are in a "position" to scrutinise; and then those art critics shrug their shoulders and declare photographs are only mechanical productions, and photographers may be anything they please to designate themselves in this world so long as they do not arrogate the title of artist.

Why is not the theorist a consistent "bundle of atoms?" Why does he not cry "Excelsior!" and proclaim the dogma that before studying the photograph in accordance with the eye and focal length of lens, noting the size of the diaphragm used must be duly ascertained and the pupil of the human eye contracted or dilated accordingly? The subject will resolve itself into an equation something after this fashion:—Let x represent the pupil of the eye when examining a photograph taken by a five-inch lens, aperture $f/4$. Required to know what will represent that eye when looking at another photograph taken with a six-inch lens, aperture $f/32$, Q.E.D.

Another subject which has been discussed with most profound acumen and unbounded fertility of language is that of the swing back. The majority of the text-books and manuals on the "art" (?) of photography unhesitatingly advise the novice, when he cannot get the top of that church steeple or Jubilee memorial into his picture, to at once tilt his camera and swing his back; and the good people who propound these crazes write their next sentence on the "art" (?) of photography and once again the art critics give their shoulders another shrug, telling the world at the same time that a photographer never can be an artist for he knows nothing whatever of art. Now, who in possession of all those natural senses with which he is supposed to have been endowed at birth, who of us in this category would lie flat on his back in the roadway to study the "varied beauties of the landscape?" The idea and the situation are alike absurd. But the absurdity is only a question of *degree or intensity*, if posing one's body with all the grace we can muster at an angle of, say, 30, 45, or 60 degrees from *terra firma*, we proceed to make what we are pleased to term "pictures," but which some people term "only photographs." We often read of the intelligent observer, or the dispassionate listener. Let us endeavour to make

this swing-back business plain, even unto him, and ask him to stand in front of any edifice and note the effect which the various architectural lines composing that building convey through his eye to his mind. Next, let him from a rocking-chair study the same building at angles varying with the elevation or depression of the seat and again note the effect. It will not for one moment compare with that obtained by the vertical position. And it signifies not whether it be the human eye or the optician's lens which has been tilted, the outrage on the laws of perspective is precisely the same, and would be committed by no one cognisant of those laws.

The photographer's ready reply, based on the manuals of his art and the dicta of the various camera-box makers, is that though the lens has been tilted the back has been swung vertical with the building, and that whatever errors have been committed by the front of his box they have been rectified by the elaborate construction behind. And once again those art fellows give another shrug and say photographers never will be artists, even if some of them are very fair picture-frame makers. Why, the photographer's reply makes the matter worse so far as regards perspective, for it proves his complete innocence of that branch of an artist's education.

There is one piece of photographic *argot* which must be noticed anent the swing back. "He must tilt, or he cannot get the subject on his plate." What a confession from one who aspires to be considered an artist! To put this into plain English, the average photographer confesses that his mechanical appliances are such that he must resort to a cabinet-maker's dodge in order to secure the entirety of his subject, at the cost of whatever laws may happen to exist on perspective or anything else; it is all the same to him, so that he "get it"—the weather-cock on the steeple. And this "getting it in" the plate seems to be the height of but too many a photographer's ambition. It does not occur to him to procure another objective of shorter focus or of wide-angle; the machine he happens to possess must do the work, abortion or no abortion, perspective or no perspective, and the manipulator of this mass of incongruity is disgusted if some individual insinuates that photographs after all are only mechanical productions. Of course the novice is delighted with a swing back. There are some, in this weary waste which we call earth, whose backs are fearfully and wonderfully made, they are so pliable. But to put the camera box anywhere, anyhow, and by the mere turn of a screw "get it all in," this must be an advantage, a blessed state of things, which can only be fully appreciated by the phibb-backed brigade. If the top of that Jubilee tower will not "come in," and there exist no means of substituting another lens, in the name of mercy, charity, and art, leave the subject untaken, and let posterity suffer the loss rather than add another to the long list of pictorial abortions by the aid of the swing back.

There is one more subject on which the theorist loves to discuss—the fixing and the washing of the albumenised paper prints. Let them remain in the fixing solution for twenty minutes; this is the favourite time, though some incline to fifteen and some twenty-five minutes; the difference of opinion is quite natural and the theorist is most heartily welcome to it. Here is the *fact*. A representation of subject in monochrome, of more or less delicacy of tone, is to be arbitrarily released from the operation which cleanses and beautifies its lights at the expiration of twenty minutes. Prints slightly over-printed, prints slightly under-printed, prints from brilliant negatives, in which the lights are not only introduced in printing but absolutely hard, and prints from delicate negatives, wherein the lights have been considerably lowered by the operation of printing—one uniform time for removal by the theorist from the hypo bath—twenty minutes, and this time not a removal from the soda, print by print, but the soda solution is to be drained off, leaving the prints in one soddened mass, with what remains of the strong solution clinging with a not too agreeable pertinacity to each individual print. These unfortunate prints are then to be subjected to alternate washings of warm and cold water, commencing with the former after removal from the hypo. It would be interesting to know the philosophic basis on which this theory has been founded. Most of us whose experience in photography exceeds a couple of decades will remember the cardinal truths enunciated at that time and not to this day questioned on anything like authority. It was this: Photographs should not be immersed in warm water until the major portion of the hypo has been eliminated. Warm water accelerates the action of sodium hyposulphite.

The print should have been removed from the soda just at the point when further operating will unduly bleach the lights, and just at the point when a lesser time in the hypo solution will leave those lights too load in tone. Place the print judiciously removed from the hypo direct into warm water, the warm water will accelerate the action of the soda remaining in the pores of the paper, and the bleaching action will have been carried too far. Photographs which have been suffered

to remain in the fixing solution by set time may be treated to hot and cold water without detriment to their quality as works of art—they may even be immersed in strong acids without loss, because they are simply mechanical productions turned out of a dish by any dummy who can tell twenty minutes on a "Seth Thomas" clock. But how is it these theorists never advise the student that, in removal from the soda bath, the prints should be tested for fixation by transparency in the whites in transmitted light? This point attained, whether at ten minutes or thirty, any further prolongation in the solution will depend on the artistic feeling of the printer, warning him the lights are being unduly lowered or when further bleaching is necessary in order that the harmony of the subject shall be preserved. It should be remembered by the theorist that though a proof may be *fixed* in ten, fifteen, or twenty minutes, it may not be *fit for removal* from the soda under half an hour, and, on the contrary, its character may be such that a moment longer than ten minutes will suffice to remove it from the category of a work of art to that of a mechanical production.

It must have cost an infinite amount of work and a stupendous expenditure of brain power to propound the theory that washing proofs should be *alternately* in warm and cold water. Why not cold and warm? Why not two, three, five times warm to once of cold, or *vice versa*? Why not hot water exclusively, and so have a pretty kettle of hot water all round? A vast number of experiments might be safely carried out on the basis of these suggestions, which may be further complicated by a series of tables on the ratio of permanence attached to warm and cold-water washing when carried on in the full glow of the pale moonlight, and when manipulated with the lunar rays more or less screened, the former condition represented by *x*. While at it there's nothing like a real abstruse theory, and the tougher it is the better it is for its propounder.

"How many grains of salt shall I eat with my egg, doctor?" "How strong shall the fixing solution be, most learned theorists?" And from the lips of the modern oracle issues the parrot-like phrase, "Four ounces to the pint." Four ounces to the pint, with a mechanical twenty minutes' immersion, when many operators who work with brains use *eight ounces to the pint*, and out in about ten minutes, or as soon as transparent and the lights correct in tone and in relation to each other.

J. H. E. J. HARRIS.

—*Con. Number St. Louis Photographer.*

RECENT DISCOVERIES IN THE NEBULÆ BY MEANS OF PHOTOGRAPHY.

It is not so long ago that it was pronounced to be "impossible" to photograph the nebulae at all. The enormous improvement in the sensitiveness of photographic films within the past few years has permitted wonderful advances. Some of the results of such work are so recent that they are known only to the readers of scientific journals, and they are so important that I wish to exhibit them here to a wider circle.

The very first photograph of a nebula was taken in September, 1880, by the late Dr. Henry Draper, at his observatory at Hastings on the Hudson. In 1881 he obtained, with an exposure time of 104 minutes, a picture of the nebula of Orion, which showed stars that were fainter than the faintest visible to the eye in his telescope (a refractor of 11 inches aperture, made by the Clarks, of Cambridge), and which displayed essentially all the details in the nebula which I had been able to make out with the much larger telescope at Washington (26 inches aperture). Moreover, my work at Washington required years, while his was done in one night. This photograph of Draper's led the way, and showed what might be expected from future work of the same sort. Draper's early death closed his series of studies in this path. His researches were taken up by Mr. Common, of London, who built a three-foot reflector for the purpose, and who succeeded (in 1882) in making a magnificent picture of the Orion nebula.

Mr. Roberts, of Liverpool, using a reflector of 20 inches aperture and of short focus, has made a series of pictures of this nebula also, which serves to show the law according to which it is built up. His series begins with a negative exposed for five seconds only. This exhibits the central bright stars of the nebula and a small portion of the brightest nebulosity. Successive pictures with exposures of 30, 60, 180, 360 seconds show more and more of the nebula itself, and the last one gives all of the object which can be seen in a powerful telescope.

Not only is everything visible, but it is permanently registered, and the six minutes of exposure have sufficed to make a map for which a year's work might be necessary if done with the eye alone.

Other photographs of 15, 30, 81, 210 minutes show more and more of the nebula and extend its limits over vast spaces.

The various photographs of the series, taken together, establish the order of brightness of the different parts of the nebula, and give a set of lines of equal light, by means of which its structure becomes more intelligible.

It is of Mr. Roberts's recent wonderful photographs of the nebula in Andromeda that I wish more particularly to speak. This great nebula is just visible to the naked eye, and is mentioned in Sufi's *Uranometry* (about 900 A.D.), and is a well-known object to possessors of small telescopes. Little was added to our knowledge of the nebula until Professor Bond, at Harvard College Observatory, made a careful study of it in 1848. The nebula was shown to have an immense extent, and the most curious feature exhibited was the presence of two long, straight, vacant spaces or canals extending through most of the central portions. The work of Professor Bond was repeated with the same telescope about 1874 by M. Trouvelot.

Little can be added by the eye to this splendid picture. Small details can be corrected, but it must be accepted as a substantially correct representation of what the eye sees with even a very large telescope.

In a part of the same object as photographed by Mr. Roberts, with an exposure of two hours for the first time, we obtain some adequate conception of the true forms of this great nebula.

Instead of the two straight rifts of Bond, sharply terminated at both ends, we find two huge vacant *rings* of blackness surrounding the central portions. Other rifts and vacancies exist in the photograph which are quite invisible to the eye, and the whole nebula is exhibited in a new light.

It is seen to consist of a system analogous to that of the planet Saturn—a central mass surrounded by rings, which are separated from the central body by empty spaces. Like the rings of Saturn, the rings of the Andromeda nebula are probably composed of myriads of small discrete solid particles revolving in swarms about their primary. The vacant spaces in Saturn's ring are caused by the attractions of the larger satellites of that planet on the smaller particles of the ring. No doubt the vacant spaces in the nebula are caused in the same way.

It is possible that the two brighter masses lying beyond the central bright body of the nebula are, in fact, the effective causes of the vacant spaces. But we can safely go a step further in our search for analogies. Laplace considers Saturn as a striking proof of the nebula hypothesis which he proposed. The planet represented the final stage of the very process by which the solar system might have been condensed out of the primal nebula. In the Andromeda nebula do we not actually see before us a still earlier stage of the same process, where worlds are forming, though not yet formed? Are not a planet like Saturn, the Andromeda nebula, and one of the inchoate gaseous nebulae, three successive steps in the evolution of the universe?

The interval of time required for the progress from one of these stages to the next is so immense that the whole of human history is a mere instant in comparison. But have we not a different means of tracing these steps? As Sir William Herschel nobly said in 1789, "The maturity of a sidereal system may thus be judged from the disposition of its component parts. . . . This method of viewing the heavens seems to throw them into a new kind of light, and one advantage that we may at least reap from it is that we can, as it were, extend the range of our experience to an immense duration. For is it not the same thing whether we live successively to witness the germination, blooming, foliage, fecundity, fading, withering, and corruption of a plant, or whether a vast number of specimens, selected from every stage through which the plant passes in the course of its existence, be brought at once to our view?"

From this point of view we may regard Mr. Roberts's discoveries in the Andromeda nebula as the most important which have been made since the time of the Herschels. His photograph really represents a stage in evolutionary history which has been prefigured by the eye of reason, but which is new to the eye of sense. We cannot doubt that the methods which he has employed are to yield more evidences of the same nature. And it is sure that his methods are to be faithfully followed up.

The brothers Paul and Prosper Henry, of the Paris Observatory, have devoted the past few years to perfecting their apparatus for astronomical photography as applied to the making of star charts. In the course of their work they have discovered an entirely new nebulous region connected with the principal stars of the Pleiades group. Formerly only one nebula was known in this group, attached to the bright star Maia.

The photographs of Paris have shown the whole group to be connected with a complex nebula.

From the upper part of the right nebosity a slender thread of light is seen to extend toward the west, passing through at least eight of the stars of the cluster. It is certain that these stars are connected with the nebula, and that the nebula is connected with the seven bright stars of the Pleiades group, and must therefore be at the same distance.

As might naturally be expected, photography is a powerful aid in the discovery of new nebulae. Professor Pickering, at the Harvard College Observatory, has explored a small region of the sky in this way, and his photographs show thirty nebulae in a region where but eighteen were previously known.

The new nebulae were faint and small naturally, but the experiment shows what can be done in the way of mere discovery.

The need of astronomy is, however, not so much the discovery of new objects as more information about well-known ones.

Dr. Gothard, of Hungary, has lately shown that even a comparatively small telescope is adequate to give this. With his ten-inch reflector he has photographed many nebulae (on a small scale necessarily), and on examining the negatives, Professor Vogel has found that even these small

pictures are superior to the best drawings of the same objects with the largest telescope. There are many similar researches marked out and waiting for experiments, and the success of Dr. Gothard has proved that giant telescopes are not essential.

The refractor of the Lick Observatory has some advantages in researches of this nature on account of its great focal length (forty-seven feet), which gives a large size to the picture. The experiments which we have so far made promise excellent results in photographing the nebulae. An exposure of ten minutes on some of them is ample. When the great telescope is completely fitted for photographic work (which will be shortly), it is to be assiduously used in this field.

I have gone rapidly over the advances which have been made in the photography of the nebulae in the nine years since the first nebula photograph was taken. The wonderful pictures of Draper, Common, Roberts, and others will have a permanent value, as they serve as means for comparison with later work, and as it is only by such comparisons that evidences of change can be detected. Photographs of the nebulae have a great advantage over mere drawings, no matter how carefully made, for such a purpose, as they are devoid of personality and record *exactly* what they see. Moreover, they command a large field of view, while the ordinary eyepiece is far too small to deal with large objects.

By exposing the negative to the light of a standard lamp (as is done at Harvard College and at the Lick Observatory), we may impress on the plate a series of standard squares of known brightness. Comparing these with the nebula, we may gain a numerical estimate of the brilliancy of each portion of each nebula examined. Such data are priceless for the purpose of detecting future changes in the nebulae.

The revelations of the Andromeda nebula photographs are distinctly new, and throw a flood of light upon the secret processes of creation itself. Not a hundredth part of the brighter nebulae have yet been photographed, and it is certain that discoveries no less important than those of Mr. Roberts are near at hand. One great advantage of the new method of research is its absolutely autographic character; and an incidental excellence is that its results are so easily exhibited to others than the observer.

EDWARD S. HOLDEN, LL.D.,
Director of the Lick Observatory.

—Scientific American.

TRANSPARENCIES—RETOUCHING, AND OTHER MATTERS.

[Abstract of Presidential Address to the Dundee and East of Scotland Photographic Association.]

IN a subject such as photography, dealing as it does so much with individual taste, there must constantly be much difference of opinion, but if criticism, however hostile, be made in a kindly way our meetings will be a source of more than pleasure to every one, and a cause of annoyance to none. The search for a suitable subject upon which to address to you a few lines has been a difficult one. The mere mention of such well-worn subjects as developers, toning baths, and such-like, cause a thrill of wearied disgust to any but the veriest beginner.

Optics, a fascinating study when once fairly tackled, somehow shows a most repellent front with its seemingly intricate and confusing diagrams. The cry generally is, Keep all theoretical matters to yourself, and say in a word how we are to make better photographs, or how to get equally good results by a quicker and simpler method. I have chosen to-night a subject which, while we must dip a little into the theoretical, has for its aim and object a purely utilitarian purpose; it is, in short, a way by which you may vastly improve your photographs, simplify the process, aid permanency, and at the same time reserve a power over the finished result which is impossible in any but this one way.

Without further mystification, I would ask whether you have ever noticed how much more true to nature a photographic transparency is than a print upon paper or other opaque base. For a long time a war was waged as to whether the modern dry or the old wet gave the finer result. Now it is almost universally admitted that, except under certain conditions, the advantage is all on the side of wet collodion, and plate makers do not hesitate to make this wet-plate quality an advertisement cry for their own special production. I have all along held the opinion that prints from wet-collodion negatives were far finer than from gelatinobromide dry plates, but I deny that the same holds good with transparencies from the same negatives.

Gelatinobromide negatives, intensely beautiful in their delicate gradations, seem to me to be altogether unsuited for printing from upon an opaque base, but when used to produce a transparency from them, the case is altered, and an average wet-plate negative will fall far short of the gelatinobromide for this purpose. I do not say that the best productions of wet collodion are not up to the best dry plate, even in transparency work, but what I do say is that the average of good work is far higher from gelatinobromide than from wet plates. But you will wonder what all this has to do with the subject in hand; surely a return to wet collodion is not to be suggested? No, certainly not; but it is to be suggested that for the highest efforts of the photographer, printing from gelatinobromide negatives upon an opaque base be discontinued. This does not necessarily imply that all the best pictures are to be put up as transparencies. Although nothing could be more beautiful, it would be highly inconvenient; but, in short, my suggestion is that a transparency thin and delicate be

made from a negative either the same size or enlarged, and this to be superimposed upon an opaque base.

At first sight this proposal seems to offer no advantage, but consideration for a moment will show that it has many. Let me enumerate some of them. First, then, the gradations are far finer in gelatino-bromide than in any printing process upon paper. Whatever there is in the negative will be found in the transparency. Especially is this true as to detail in the dark parts of the picture—a vital point, as this is just where gelatino-bromide fails when printed from in the ordinary way. Secondly, by placing this transparency upon slightly tinted paper, different effects may be produced. Thirdly, by roughly rubbing in with a stump upon the paper base a lighter or darker ground, the light and shade of the picture as a whole is thoroughly under the control of the operator. Fourthly, the transparency may, with the same trouble, be any reasonable size. Fifthly, a carefully made and well-washed transparency upon glass is, in all likelihood, quite permanent. And, sixthly, the whole process is quite within the powers of the average operator, and opens up a vast field for the exhibition of individual taste. By working roughly (but with correct intention) upon the paper background, high lights may be subdued, or dark parts lightened; clouds may be strengthened, or altogether put in, and, in short, one has a reasonable control over what he intends to produce.

But there may be objections to this idea upon certain grounds, and, first, it is not a new idea. Granted; but when introduced many years ago the wet process was in vogue, transparencies infinitely more difficult to produce, and, consequently, the game not so much worth the candle; besides, I do not think that it was ever suggested to work upon the light and shade as I suggest, but merely to add a few pencil hatchings to simulate a pencil sketch.

But, it may be argued, if so much is to be done by hand, is there not the old objection to retouching in a doubly aggravated form? If it be objectionable to obliterate by means of the hand almost invisible defects, how much more so to boldly model the whole light and shade of a picture, and, indeed, almost strive to rob it even of the semblance of a photograph? I reply to that, that from the overwhelming number of those who use retouching it is plain that the consensus of opinion is in favour of its legitimacy, nay, of its necessity, at least in the meantime.

Granted, then, that it be allowable to remove by hand the almost invisible defect, I hold that the only limit to the practice is the limit of necessity, and if it be proper to add anything by hand, the amount to be added must be settled by what is required. Tried by this test, the plan of altering boldly the whole light and shade of a photograph is perfectly legitimate, for the principle involved is the very same whether you remove a freckle or illuminate a whole hillside.

But is there any advantage in this plan over, say, printing in platinum or gelatino-bromide paper and working upon that? There is a very great advantage, in so far as the artist is unhampered by the fear of spoiling his picture after having brought it so far. He works upon a piece of plain paper which is to be placed behind his picture, but which if it be not quite to his taste, may be destroyed and another made in a few minutes, leaving his transparency as good as ever; besides, not nearly the same skill is required, for the work is only to show through from behind, and may be broadly put on. The objection, that even this requires some little artistic ability on the part of the operator, I hold to be no objection at all, for a photographer without some little artistic ability is not worthy the name, while those who sigh for a method whereby their taste may have freer scope will think this requirement a recommendation in place of an objection.

There is one other point which I fancy may be objected to by some, and that is, that by this method, while it may give a very good result, it is a result which cannot, without the very same amount of trouble, be re-duplicated. After all your trouble you cannot throw off half a dozen copies even, but must content yourself with a single picture. From a commercial point of view I admit the objection, unless, indeed, the lithographer be called in to produce your backgrounds by the hundred; but for the amateur this is no objection, for he generally wants only one copy, and it must not be forgotten that difficulty in reproducing a certain article adds immensely to the value of the original. I am convinced that those who give this method a trial will very much enjoy the power which it puts into their hands, and although the first attempt may not be entirely successful, I am sure that they will immediately feel that the process is capable of great things through practice. J. K. TELLOCH, M.B.

Foreign Notes and News.

THE scientific study of the phenomena of lightning has, like many other subjects, to thank photography for a new discovery. Wheatstone stated as the result of his observations that the lightning flash lasts for at most one one-thousandth of a second. M. Trouselot has, however, proved that this opinion is incorrect, and that the passage of lightning is so far from being instantaneous that it even in some cases takes up several seconds. This M. Trouselot has demonstrated by holding the camera in his hand and moving it backwards and forwards during the period of exposure. The image of the lightning on the plate appeared after development in the form of a number of broad horizontal bands parallel to the direction

in which the apparatus had been moved, thus presenting the appearance of a small flag fluttering in the wind. Trouselot repeated these experiments a number of times, the result showing in every case that the electric discharge is not instantaneous, but gradual. Those gentlemen who are in the habit of priding themselves on the wonderful dexterity they display in lightning catching will probably receive this piece of news with mortification.

THE recent meeting of the various German Photographic Societies at Weimar appears to have afforded an opportunity of illustrating the truth of Goethe's remark that "There are properly speaking no subjects that are unpoetic," for Herr Seidel, Professor at the Grand-ducal Sophia Institute in that town, bade the assembled photographers welcome in a poem of which, as it presents the various aspects of photography in a very attractive light, we venture to append a translation.

"All welcome to you with your 'Art of Light'!"

That bids e'en lightning render it assistance,
So that an image from the gloom of night
Grows as we wondering gaze into existence.

To picture the bird's flight, the bounding steed,
And human life in all its varying phases,
The cloud's course through the sky, the vessel's speed,
All this your art in thoughtful wise embraces.

The human face, too, whether young or old,
Into forgetfulness you keep from dying,
And for the world its likeness fresh you hold,
When he it pictures in the grave is lying.

The daring bridge, the castle's mouldering wall,
Town, palace, landscape, and cathedral spires,
In your 'dark chamber' they are focussed, all—
Must serve as models when your art requires.

Nor sun, nor moon through an eclipse can pass,
Her transit even Venus cannot make it,
But that you come in troops, with lens and glass
And camera, on the look-out to take it.

So enter here—here you are welcome quite
In this our home of high association,
Where dying poet's lips spake, 'Light, more light!'
Of your new art as in anticipation."

THE last number of the *Vienna Photographische Correspondenz* devotes a good deal of space to the question of diffusers for electric light photography. Captain Himly, a translation of whose paper on *Hydroquinone* we gave some time ago, has devised a very ingenious arrangement: Two electric lights are placed within a large sheet-metal hood internally coated with white glaze; the lights are so screened that no direct rays escape, and the studio is illuminated by the diffused light reflected from the glaze only. Another simpler and apparently very practical arrangement is that of Ronzellen. This consists of rigging up a large paper shade and throwing the light on it by means of a concave mirror, which gives a very good indirect illumination. The light is, of course, so screened that none of the direct rays fall on anything but the paper screen.

A GERMAN contemporary some time ago drew attention to the occurrence, both this year and the year before (when it was first observed), to a very interesting atmospheric phenomenon—the appearance, namely, during the summer months of luminous clouds during the night. Trigonometrical observations carried out at a number of different points established the surprising fact that the height of these clouds varies from sixty to seventy kilometres above the sea level. This extraordinary altitude enables us to supply a very natural explanation of their appearing luminous at times when ordinary clouds are no longer directly visible. But it excites our wonder as to how clouds could ever have reached or remained suspended at such a remarkable elevation. Dr. Koppe, of Brunswick, believes them to be due, in all probability, to the volcanic eruption which took place in Java on such an extraordinary scale in 1884, and to be consequently, in all probability, formed of sulphuric acid which was then projected into the higher regions of the atmosphere, where it has since condensed. As they present many interesting peculiarities of form and structure, it is satisfactory to know that special stations for observing them have been established at Berlin, Rathenow, Nauen, Magdeburg, and Brunswick, that the Berlin observatory has had a number of special instruments made for the purpose, and that a valuable series of photographs of them has been obtained.

DR. VOGL gives the following receipt for the employment of eikonogen:—

1.	
Crystalline sulphite of soda	40 grammes.
Eikonogen	5 "
Distilled water	500 c.cm.

2.	
Carbonate of potash or calcined soda	60-75 grammes.
Distilled water	500 c.cm.

For use, mix equal volumes of 1 and 2.

* Goethe.

OPINIONS OF THE LONDON PRESS ON THE PHOTOGRAPHIC EXHIBITION.

The Graphic.

THERE is little novel to be noticed this year in the Photographic Society's Exhibition, save that the number of silver prints are becoming fewer and fewer each season, and that the various methods of platinotype are fast growing into universal favour. More artistic taste, also, is shown in the arrangement of figure groups, and there is decidedly less tendency to pose the models in their best clothes, or in borrowed plumes, which make them look profoundly uncomfortable and unhappy, or as stiff and stark as mannikins in a marionette show. More care is taken to choose purely natural subjects—such as sailors on a quay—fisherwives gossiping at their house-door (of this there is a charming example shown, *Wives and Wrens Ashore*, by Mr. David R. Clark)—or a couple of lovers wandering down a country lane—such as *Sweet Spring-time* (by the way, the landscape looks far more like autumn), by Ralph W. Robinson. Two especially good examples of this class of photography are *Shrimping*, by Mr. Gay Wilkinson, jun., which has been deservedly awarded a medal; and Mr. Lyddel Sawyer's *Here's a Nest, Lads*. Of the Gerard Dow-like interiors, in which, some years since, Mr. Adam Diston so excelled, there are but few examples, the only one above the indifferent being *A Pleasant Study*, by John Terris. There are some very good landscapes, but scarcely above that high average which has been attained of late years; while the mountain views shown can in no way compete with the well-known views of the High Alps by the late Mr. Donkin, the admirable Caucasus views of M. Déchy, or Mr. Frith's views of Norway. A certain pitch of excellence appears to have been attained by the majority of the exhibitors, but except as regards the actual printing no material advance seems to have been made upon last year's work. We may, however, mention some views on the Italian lakes by W. Dillworth Howard; the *Head of Derwentwater*, by Green Brothers; *Park Place, Henley-on-Thames*—a good example of what can be done on a celluloid film—by J. Bracebridge Hilditch; and a seascape, *Fingal's Cove, Staffa*, by D. H. Macfarlane. Turning to sea studies, William Parry sends two good photographs of H.M.S. *Victoria*, Messrs. West and Co. some yacht studies, and Mr. Henry C. Peabody some especially clever snap shots of the yachts *Beetle* and *Rosalind*. Of portraits there are no end, and of these there are some particularly noteworthy exhibits by professional photographers. Mr. R. Faulkner sends an especially fine likeness of Professor Stewart Blackie, which a few years since might well have passed as an etching by Rajon; Mr. W. J. Byrne some admirable *At Home* portraits, taken in ordinary dwelling rooms, and several excellent portraits of the Emperor of Germany, taken last August at Osborne; and Mr. Ralph W. Robinson, a large number of Royal Academicians, taken in their studios. There are comparatively few natural history studies, but *The Stag at Eve had Drunk his Fill*, by Miss Florence A. Harvey, is one of the prettiest pictures in the room, while Mr. A. R. Dresser sends some extremely comical photographs with a hand camera of a dog jumping through a hoop. The animal's various attitudes should be noted by animal painters. Much disappointment will be felt at the paucity of photographs with the detective camera, though these miniature cameras form the most interesting section of the exhibit of new apparatus.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 14.....	North Middlesex Club	Jubilee Hall, Hornsey-road.
„ 15.....	North London	Myddelton Hall, Upper-st., Islington
„ 15.....	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.
„ 15.....	Bolton Club	The Studio, Chancery-lane, Bolton.
„ 16.....	Bristol and W. of Eng. Amateur	Queen's Hotel, Clifton.
„ 16.....	Bury	
„ 16.....	Hyde	
„ 16.....	Manchester Camera Club	Victoria Hotel.
„ 16.....	Edinburgh Photo. Club.....	5, St. Andrew-square.

„ 17.....	London and Provincial	Masons Hall Tavern, Basinghall-st.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 3.—Mr. W. M. Ashman in the chair.

The CHAIRMAN inquired whether the method was known by which the red prints shown at the Photographic Exhibition by Colonel Noverre had been produced.

Mr. W. E. DEBENHAM had been informed that they were printed upon rough paper, salted and silvered, and not toned.

Mr. A. COWAN inquired as to the method of using a telescope for producing large images of distant objects.

Mr. A. HADDON said that a single lens of very long focus would be best to use, but if a telescope were employed the eyepiece should be separated farther from the inverting lens than when used for observations. He illustrated his remarks by diagrams upon the blackboard, and explained that both definition and illumination would be improved (if a terrestrial telescope was in question) by removing the inverting lens.

Mr. DEBENHAM suggested the use of a microscopic objective in place of the eyepiece for forming the large image.

A query was read:—“What effect has alum upon the developed plate?”

Mr. COWAN replied that it hardened the film, decolourised the pyro stain, and caused the negative to dry more quickly. When making lantern slides it was important to have the shadows quite free from stain, but the same effect could be got without alum by using a large amount of sulphite in the developer. A very long washing to remove all pyro from the film before fixing tended much to clear shadows, but did not equal the effect of the alum bath.

The CHAIRMAN remarked that an acid wash before fixing would, by leaving a little acid in the film, liberate sulphurous acid in the fixing bath, which would act powerfully as a decolouriser. On the whole, he preferred chrome alum to potash alum as a bath for gelatine plates.

Mr. C. H. COOKE also preferred chrome alum.

The CHAIRMAN doubted whether ordinary alum was harmless to the negative, but chrome alum was. By introducing the negative to a chrome alum bath and then placing it in the fixing bath he did not see that anything could arise to damage the negative. As to mixing alum and hypo, it had been claimed that the hypo would do more work in fixing when so used than separately, and it had been so stated in the last photographic annual. He had tried it carefully, but did not find the hypo to fix either more in number or more quickly.

The subject of different developers being brought forward, Mr. H. M. HASTINGS said that he had found nothing like eikonogen for instantaneous pictures. For other work he was not so satisfied with it, as if the negative was at all over-exposed it could not be kept back so readily as with pyro. The image, even when very dense-looking, allowed a certain amount of light to pass.

Mr. HADDON: Like the image formed by ferrous oxalate, which required to be much denser than the pyro-developed image. There was no reason why eikonogen and pyro should be mixed. As to sending out the eikonogen, it would be better to use bottles that could be kept air-tight with corks or stoppers than tins, as at present. When once opened, all the contents of the tin should be mixed at once, as the air soon altered the substance.

Mr. HASTINGS had not found the slight difference which access of air for a moderate time to the tin effected in the eikonogen made any difference in the practical working of the solution.

Mr. W. H. HOOPER was elected a member.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The Committee of this Association met on the 4th instant at 181, Aldersgate-street, E.C., Mr. W. Bedford in the chair.

A considerable time was devoted to discussing the affairs of the Association.

The Photographic Society having granted the use of their Exhibition on Friday, November 8, for the benefit of the Photographers' Benevolent Association, it was decided to give a lantern display, as hitherto. The Gallery will be open from seven till ten p.m., and it is hoped will receive the support the object deserves. The charge for admission will be 6d., or tickets can be obtained of the Secretary, Mr. H. Harland, 83, Hawksley-road, Stoke Newington, N.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

OCTOBER 1.—Mr. A. Mackie (Vice-President) in the chair.

The Hon. Secretary showed six framed platinotypes of views in the Isle of Wight and at Hampstead.

Mr. G. J. Clarke exhibited some prints on bromide paper.

It was determined to hold the first lantern evening of the season on Tuesday, November 19; and the annual meeting of the Society will be on Tuesday, November 5. There will also be an exhibition of members' work on the third Tuesday in February.

The SECRETARY then read a paper on *The Relation between Exposure and Development, and the Subsequent Improvement of Negatives*. In his opinion there was no exposure which could be taken as a standard and called a “correct exposure,” as could be proved by giving a plate a normal exposure for one developer and developing it with another, when that exposure would in most cases cease to be normal; again, if on commencing to develop a plate it proved under or over-exposed, it could be made into a good negative by modifying the solutions or using other developing agents, as hydroquinone or the more recent eikonogen, with the preliminary hypo bath, for under-exposure; and the citrates of potash or soda, in conjunction with bromide of potassium, for extreme over-exposure, in some cases using a preliminary bath of bromide of potassium. For subjects with extreme contrasts it was advised to give a full exposure and stop the development early, thus producing a soft printing negative. The action of citrate of potash and bromide of potassium was explained, and the various methods of correcting under and over-exposure given, including a redevelopment method. For the after improvement of negatives, a five-grain to the ounce solution of ferricyanide of potassium and another of hyposulphite of soda of the same strength, and mixed in equal proportions, was recommended for clearing out fogged shadows in over-exposed negatives when the development had not been properly controlled. The image would be reduced to almost a ghost, and should be intensified with the mercury and cyanide of silver process, when the result would be a bright negative. Several methods of intensification and reduction were given.

Mr. L. MEDLAND stated that when developing with eikonogen he had always seen the first plate in the solution veiled over when using the developer without bromide, the second plate was not veiled.

Mr. MACKIE considered that a certain amount of bromide would be dissolved out of the first plate and account for the other plates being correct.

The HON. SECRETARY stated that he had not noticed any veiling when using the eikonogen developer without bromide for under-exposed plates.

Mr. DRAGE said he had always used bromide of potassium, and found that any amount of density could be obtained when using it; he also found the old solution very useful for developing bromide paper.

Rev. E. HEALY stated that by using a careful method of developing he had obtained one hundred good negatives out of one hundred and ten exposed plates, using a pyro and ammonia formula, and commencing development with a minimum of ammonia.

Mr. MACKIE said that chemicals should be kept, as far as possible, in ten per cent. solutions; he also said that if negatives were examined in daylight after taking them from the hypo bath they would be reduced in density, and if left long in a bright light they would be stained yellow as well; they should be washed before bringing them from the dark room.

The next meeting will be on Tuesday, October 15, when Mr. Clarke will read a paper on *Enlarging for Amateurs*. Visitors are invited.

LEWES PHOTOGRAPHIC SOCIETY.

OCTOBER 1.—The President in the chair.

Messrs. S. Norman, A. Webbing, and F. Tait were elected members.

The PRESIDENT then read his annual address, which touched on various matters relating to photography, and the paper was supplemented by two very fine Daguerreotypes, produced by Daguerre himself, and a print $19 \times 7\frac{1}{2}$ from a wet-plate negative. The President remarked that those who were acquainted with the wet-plate process would know what a difficult matter it would be to coat a plate this size with an even film.

At the next meeting, which will be held November 7, Mr. P. Morris will open a discussion on *Developers*.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

OCTOBER 2.—The President (Mr. William Shaw Adamson) in the chair.

Mr. John Duke was admitted a member.

It was agreed, on the motion of the Secretary, that the subscription of honorary members be reduced to 5s.

It was agreed that arrangements be made for an exhibition next spring, the Committee to draw up a scheme and submit to the next meeting.

Thereafter, a large number of slides were passed through the lantern. The slides exhibited were the work of Dr. Anderson, Messrs. Ross, Braid, Mackie, and Stewart.

LEEDS PHOTOGRAPHIC SOCIETY.

SEPTEMBER 19.—Mr. Godfrey Bingley in the chair.

Referring to the subject of development Mr. S. A. WARDINGTON (the Hon. Sec.), said he did not agree with any developing formula in which you mix two solutions in equal parts to form your developer; the chances were certainly against the developer as mixed with the subject and the exposure. The developer he recommended, and which he had used for some years, was that given by Messrs. Whitten & Walnwright with their instantaneous plates. The following is the formula with a slight modification, namely, using the pyro in solution with meta-bisulphate of potass:—

Pyro.....	20 grains.
Meta-bisulphate of potass.....	20 "
Water.....	10 ounces.
2.	
Ammonia, s.g. 880.....	1 ounce.
Potass bromide.....	60 grains.
Water.....	3 ounces.
3.	
Potass or ammonia bromide.....	60 grains.
Water.....	1 ounce.

There was certainly nothing novel in the formula, but it would, he believed, strike every photographer that with solutions mixed in this form, a tremendous power was placed in his hands. Two grains of pyro per ounce was the most that need ever be used, and by diluting with water, any strength under this could be obtained. The ammonia solution was so strong that four drops to the ounce of the pyro solution were quite sufficient to start development, and two or three drops of the bromide solution would instantly check a too rapid development; indeed, if a Royal Commission was appointed to inquire into the best formula for a developer, he believed that this, or one very similar, would be recommended. In using a stop, Mr. Warburton said he preferred the smallest he could use under the circumstances, and for general use U.S. 32 or 64 were the ones he used most. Referring to the subject of "backing" plates, there is no question as to the great advantage to be gained, and the following was a capital mixture for the purpose, drying easily, not powdery when dry, and instantly removed by a wet sponge before developing.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE following are the Judges' awards in the lantern slide competition:—Class A (open to all professionals and amateurs), silver medal, Mr. J. W. Wade, Manchester; bronze medal, Mr. Cyril Frith, Bognor. Class B (open to amateur members of the Association), silver medal, Mr. Edgar G. Lee, Colliercoats; bronze medal, Mr. Henry R. Procter, Tynemouth.

A selection of the slides (about two hundred) sent in for competition will be exhibited at the Literary and Philosophical Lecture Hall, Newcastle, next Wednesday evening, by means of the optical limelight lantern.

The gentlemen who kindly acted as Judges were:—Messrs. J. G. Allison, P. M. Laws, and C. J. Spence. The medals were the gifts of the President (Mr. A. S. Stevenson, Tynemouth) and the Vice-President (Mr. J. P. Gibson, Hexham).

The following is a list of the slides that obtained the silver and bronze medals in Class B:—Silver medal, Mr. Edgar G. Lee, Colliercoats: *Swans at Roar, Drunken Ship, Highland Cattle, On the River Wear, Holiday Time, Among the Surf*. Bronze medal, Mr. Henry R. Procter, Tynemouth: *The Shades of Evening, Crammock Water (Winter), Crammock Water (Summer), Young Alligators, The Cobble Cottage, Scale Force*.

Class A, six entries, two hundred and fifty-one slides received. Class B, six entries, sixty-three slides received.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION

OCTOBER 3.—Dr. J. K. Tulloch (President) in the chair.

Seven applications for membership were handed in.

The President then delivered his opening address [see page 670].

Dr. Tulloch exhibited a transparency, $8\frac{1}{2} \times 6\frac{1}{2}$, enlarged from a quarter-plate negative, with a paper background worked upon as suggested in his address, and backed with a piece of plain glass, the whole being bound together with strips of paper. The result was artistic and much admired.

Several good negatives were shown which had been developed with eikonogen. So few of the members had tried this new developer that very little information was elicited as to its working capabilities.

Two negatives on Ilford plates were sent to the meeting by a beginner, and an explanation was asked of the cause of the colour of the deposit being similar to that of a wet-plate negative. The developer used was ammonia-pyro procured from a dealer.

A member present knew the formula of the developer, and that it contained an excessive quantity of sulphite of soda; the developer had probably been made up for a considerable time, and the cause of the appearance of the negatives was assigned to the conversion of the sulphite into sulphate.

Correspondence.

Correspondents should never write on both sides of the paper.

EIKONOGEN.

To the EDITOR.

SIR,—As some correspondence has taken place with reference to our note to Messrs. Marion, re the above developer, we think that some explanation is due. At the time we wrote the letter, we did not in the least anticipate that it would be used for publication, and therefore it was greatly deficient in detail. For many years we have prepared most of our solutions on the rational ten per cent. system, and therefore, when the new developer was brought before our notice, we naturally made it up on the same principle. The proportions we mentioned answered perfectly in our own practice, as the whole amount of stock eikonogen was usually diluted at one time, and therefore, if any portion was undissolved, it was immediately taken up when the full bulk of water was added. The publication of the letter was, in fact, premature, as we very shortly found that "eikonogen" was not soluble to the same extent as most other chemicals, and therefore unsuitable for ten per cent. strength. The weaker solution mentioned by us to be used for developing, viz., one in a hundred, should therefore be prepared in the first instance. In all the correspondence on the subject, the principal point of our letter appears to be entirely ignored, viz., a simpler method of preparing the developer than the complicated instructions sent out by the makers.

The developer is undoubtedly very powerful, as, with the sole addition of sulphite of soda, it is capable of producing most excellent negatives, but at a slower rate than when used with washing soda. A longer experience with it has proved to us that the most suitable solutions for developing, in order to secure the finest effect of detail and density, are eikonogen, one ounce in a hundred ounces of water, plus four ounces of sulphite of soda, and soda (washing) one ounce in a hundred of water.

For normal exposures, equal quantities of each, but varied at discretion in the same manner as solution of pyro and ammonia, according to exposure, &c. For instantaneous work and some effects of lighting, stronger solutions of both are advisable, say one in fifty. In ordinary every-day use, this method of preparing the developer would be found to possess extreme simplicity, which we think any of your readers who may have seen the original formula sent out by Messrs. Marion will admit is not possessed in the complicated description of "parts," "grammes," "grains," and "drachms," appearing to be an imperfect or possibly too literal translation of the German formula. Solutions of bromide and soda at ten per cent. strength can be kept in reserve for use if required, and we can personally vouch for the quality of the results obtained by the above-mentioned system.—We are, yours, &c., FRADELLE & YOUNG.

216, Regent-street, London, W., October 5, 1889.

NUKTIGONIA AND DAYLIGHT DEVELOPMENT.

To the EDITOR.

SIR,—Nuktigonia, as explained in your last issue, appears to mean very much the same thing as *Development in relation to Eyesight*, which is the title of a short article I wrote for THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC, of this year, wherein it is proposed to assimilate the pyro and hydroquinone developers in colour with that of the iron, which is known to be very light-resisting, by the addition of some suitable dye, and thus do away with the necessity of excluding so much light from the developing room. The fact that a plate had been developed without fog, by means

of oxalate of iron, in *daylight* was recorded by me in THE BRITISH JOURNAL OF PHOTOGRAPHY, I think, about six years ago, but others may have tried the same experiment as early. However, the fact that a plate can be so developed is now generally known, and it is well that Brother Jonathan has caught the idea of daylight development, for he is an ingenious, practical fellow, and therefore most likely to help us in our attempt to open the dark-room window. Eikonogen affords some protection to the plate by reason of its colour (in solution), particularly when it has become very brown through use and age. A little of this mixed with a portion of the new developer is a great advantage.

By the way, would it not be an advantage to both suppliers and users of eikonogen if the discoverer would vouchsafe to tell us more exactly what ought to come out of the unique boxes we are supplied with? Like another of your correspondents, I looked for a "white crystal powder," and, behold, a powder more like homœopathic cocoa came forth! It is declared to be "absolutely free from *poison*," but unless this description is more accurate than that of its colour, it would be unwise to taste eikonogen.—I am, yours, &c.,

W. HANSON.

71, Great George-street, Leeds, October 4, 1889.

PHOTOGRAPHING OF PREPARED CANVAS, ETC.

To the Editor.

SIR,—The number of THE BRITISH JOURNAL OF PHOTOGRAPHY for September 27 contains an article on *Photographing of Prepared Canvas, &c.*, by W. H. Davies, in which the following lines appear: "But it is perfectly patent to all who choose to look that it" (photography) "has quite revolutionised the landscape art, not only of this country, but of Europe, with perhaps the single exception of Holland and the Low Countries." It would be interesting, indeed, to learn in what way the landscape art is for a single instant revolutionised by photography.

It is further stated that "several of the most famous names in art circles are content with either copying early (?) but carefully drawn designs by the use of our art, but go much further than that and get the same reproduced on the canvas or the panel prepared for painting." I should like to know what advantage the artist would earn by such manipulation; and I deny the truthfulness of the insulting assertion that an artist exists who has "publicly contemned photographers and their art, but who was not above accepting the hundreds of pounds which have been got for his pictures, without mentioning the fact that they were painted on photographic copies of his own work truly, but still to the extent stated aided in the mechanical reproduction by photography."—I am, yours, &c.,

F. B.

Liverpool, Oct. 7, 1889.

THE LIMELIGHT AND BRIN'S OXYGEN

To the Editor.

SIR,—About the middle of August some of your readers may remember that I made some remarks, based on the experience of the preceding winter, concerning the want of purity in oxygen as then supplied by the Brin Company, and consequent deficiency in the light, and in the hope of eliciting from them information on the subject. About a month after I received a letter from the Company, explaining past difficulties with which they had had to contend, stating that these had been overcome since February last, after which date they were sure the oxygen supplied had been satisfactory, and asking me to visit their works and assure myself of what had been done, and of what they were now supplying. This I took the earliest opportunity of doing, and it is only just to the Brin Company to explain matters as they have now been shown to me, and from which I am glad to know that there is not likely to be any further complaint of quality, and that the annoying delays which occasionally took place last season are not likely to be repeated.

To explain briefly a matter which, I have reason to believe, is regarded generally with considerable interest: not only has an entirely new furnace been built, but the construction has been in an important respect radically altered and the old one discarded. In the old furnace the long iron retorts were all arranged horizontally, the ends coming to the front of the furnace; and the changes of temperature, incidental to the process as then conducted, causing expansion and contraction, led to constant slight leakages at the joints, which were continually causing trouble, by allowing atmospheric air to leak in whilst the oxygen was being withdrawn. Vexatious stoppages, as well as variation in purity, were thus caused, and occasioned constant study to remedy the weak point. In the furnace or producer now built, and at work under the superintendence of Dr. Thorne (the Company's chemist), all the retorts are arranged vertically, and the temperature is kept constant, while the work is done by altering the pressure. All retort leakage appears by this means to be overcome, and they yield an oxygen of at least ninety-five per cent., whilst the small impurities introduced by imperceptible leakages in filling the cylinders do not appear to reduce the standard as delivered to the public below an average of ninety-three, ranging generally from ninety-two to ninety-four per cent. The gas is regularly tested morning and evening, and the ordinary evening test whilst I was there fully bore this out. There was no disguise about the difficulties of the past, especially whilst the old furnace was—as the Secretary expressed it—"on its last legs," and it is a real satisfaction to find that they appear to have been now

overcome. We had a little trial of some matters I had brought down and the light was certainly as fine as could be wished for, with a tolerably powerful jet of about 700 candle-power.

Zirconia.—Dr. Thorne is experimenting with the German material I mentioned in the same letter, and showed me specimens which had been incandescent—though not with strong jets—for three weeks. The Company have every hope of introducing this material into this country during the winter. As I supposed, it is not pure zirconia, which is all the better; and if it can be moulded in thin discs, I have considerable hopes of it.

LEWIS WRIGHT.

October 7.

"SIDEREAL PHOTOGRAPHY."

To the Editor.

SIR,—Your readers will be glad to see, on page 593 of your well-filled JOURNAL, that Professor Morize, of Rio Janeiro, is to be one of the photographing astronomers of the Pan-national Convention at Paris.

So acute and so critical a mind cannot but be of great advantage to the perfecting of the scheme, though it seems only a pity that his Government does not grant him leave of absence to visit Paris at this time and assist personally at both the making of the instruments and arranging the mode of computing the results, in place of his remaining at Rio until the Brazilian quota of instruments is sent out in supposed faultless trim, but some of them are then found by him to have, perchance, just one defect, entirely untouched and overlooked.—I am, yours, &c.,

Glova, Ripon, October 4, 1889.

C. PIAZZI SMITH.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—Although Mr. Robinson has ventured to add a chapter in a new edition of one of his books on the subject of "Naturalistic Photography," and presumably knows what has been going on in the world of pictorial art, he is still crying to know what naturalistic photography really is. This affectation of siding with the ignorant may be an effective wile on the part of a smart controversialist, anxious more for popular support than for truth, but it will not deceive those who have felt concerned to understand these matters and who have followed throughout the discussions upon the subject. Mr. Robinson is hopeless. He will only look at, and treat, an argument from a personal and sportive standpoint. He makes cheery boast that he never says what he means. He has fully proved the truth of his pleasantry in this little controversy. But there may be some who are beginning to understand the hearings of the dispute, and, for the sake of these, I venture to try still further explanation, even definition, which Mr. Robinson craftily avoids.

I commenced with the general principles that the naturalistic artist in his study of nature seeks truth, and selects the best of everything to express what he sees and feels. This Mr. Robinson then called a definition, but now he very strangely dubs it an "airy gibe." Notwithstanding the falsities of combination landscapes, the mockery of ladies charading as rustics, and conventionalism in composition, he claimed himself a naturalistic under this definition. But he desired to add to truth some fiction or imagination, and when asked for his meaning placed in this connexion upon the word "imagination," he shifts from it as "not being our point at present." Nevertheless it is our point, and one which opens up a most important difference between the principles of the ordinary and the naturalistic schools. The one finds its admiration for representations of nature excited by the truth with which the subtleties of a beautiful scene are rendered, the other lays greater stress on the decorative cleverness with which the space devoted to the picture is filled by lines and masses. The one finds its poetry in the scene, the other claims that it is added from without. The one must work under the inspiration of the subject, the other can grind out its combinations according to rule in the studio, because it is not nature, it is so-called art that is wanted, as though art were past pictures and not capable of change and development in its principles.

Mr. Robinson calls for a clear and sensible definition of naturalistic photography as if it were a specification of a patent that was wanted. Would Mr. Robinson like to give a clear and concise definition of art? He must know that it is sufficient in these subjects to state that which differentiates clearly one set of principles from another, and, in this sense, naturalism in art may be said to be a severe regard for everything natural and true in tone, costume, action, and expression. Naturalism is a revolt from the domination of conventionalism in composition and in colour, and has resulted in a school of thinkers and workers who gain their inspiration from nature, and charm us by giving us truth, beauty, and poetry expressed in the translation of their impressions. Of course there are degrees in naturalism, and, in such a revolt, some excesses would be expected. But these are not to be feared in photography. Photography, indeed, has had much to do with the growth and development of naturalism itself, and it is harder for the photographer to offend against naturalism than for other artists.

Composition, with the ordinary school or with those who dispense it in book receipts, is a mechanical arrangement of the lines, and masses, and objects in a subject, without special regard to that subject itself, but

merely from a desire to get a pleasing pattern within the limits of the picture. Objects placed in this way almost invariably defeat their purpose by introducing a feeling of artificiality, which may be enjoyment to the composition mongers, but is felt by the naturalistic artist to mar the effect in almost every case where the object has any importance, or where the treatment of it really springs from a consideration of any of the so-called rules of composition. Composition to the naturalistic artist is a far more important and subtle matter than these mere pie-crust rules. It is that the tone, grouping, action, incident, and objects in a picture shall all be such as to help the expression of his subject by the artist, who feels that everything outside this intention is best left out.

Mr. Robinson probably cares nothing about truth of tone. Until very recently he has uttered no word upon this subject, the most important of all to the photographer. He would apparently emphasise the necessity for a wedge-shaped light coming somewhere diagonally in the picture, and call this a rule of chiaroscuro, but he would not think of enforcing the necessity for the tone of a picture being in keeping with the subject to be expressed, and true to the effect in nature. Similar differences will be found to hold in regard to treatment of costume and action between the two schools.

To turn to Mr. Robinson's pleasant personalities, I find he has again been rummaging his dictionary of quotations for more sportive gibes to serve up in place of argument. It will not probably trouble him that his quotation is not accurate. What must have given him the most chuckling satisfaction is, that the passage being so exactly applicable to himself, he should have anticipated "his friend the enemy" in the use of it.

Mr. Robinson is consumed by a fear that his opponents will never be satisfied. The question naturally arises, satisfied with what? With his defence of outrageous combination landscape painting? There has been no defence. With his justification of the use of lady models as rustics? Not a soul thinks of imitating him. With his claim as to imagination? He declines to say what he means by it. With his wonderful contention that the distinctive quality of photography is definition? He wisely allowed the refutation to pass without comment. With his vaunted challenge to competition? We are content to leave the decision as between naturalism and unnaturalism even to the public in the present or any other Exhibition.

It is one of Mr. Robinson's pleasantries to persistently write the word naturalistic as opposed to artistic. Perhaps it ought to be pointed out that the opposite of naturalism is artificialism, a point worth thinking upon by my friend.

Another personal matter. I am charged with combination printing in the several photographs near the door in the present Exhibition. No wonder Mr. Robinson was deceived by my skilful combination. In only one of the seven is there any cloud printed from a separate negative, and that is not improved thereby. Even were it otherwise Mr. Robinson knows that it is not combination of cloud and landscape which is objected to as so heinous a crime, but landscape combinations with other landscapes. There are degrees of severity in naturalism. The printing in of clouds is sometimes a necessary evil.

Mr. Robinson condemns very justly the use of the same cloud negative in more than one picture. Strange, but true, the practice which he condemns as against nature he is himself guilty of. He boasts that he has always held this practice to be against nature, and asks, "Can Mr. Davison justify it?" Certainly not, but he has some excuse in youth and inexperience, which Mr. Robinson cannot find refuge in. If using the same cloud more than once is contrary to nature in Mr. Robinson's opinion what, in the name of inconsistency, is the use of the same model over, and over, and over again in varying character, now a fisher-maiden, now a haymaker?

As to the other points, it is interesting to notice that another critic objects to one of these very photographs of mine (which Mr. Robinson states deny my theories) as carrying the naturalistic idea to excess, whatever that may mean.

I do not think any injustice was done Mr. Robinson by the reference to "attempts at historical subjects." It is not a far cry from lady models dressed as fisher-maidens to the same as historical or fanciful personages, and if Mr. Robinson objects to the procedure, it is only because he is a little less un-naturalistic than others of his general way of thinking. In a very recent article he contemplates the possible future representation of murders, bereavements, and other painful scenes, in a supreme manner by photography. After this why kick at historical subjects?—I am, yours, &c.,

(GEORGE DAVISON.)

LEEDS PHOTOGRAPHIC SOCIETY.—AUTUMN EXHIBITION OF PHOTOGRAPHS.

To the Editor.

SIR,—Will you kindly grant me a small space in your JOURNAL to reply to a large number of correspondents who ask me for particulars of the above?

Exhibits are confined to pictures by members of the Leeds Photographic Society, and no prizes are offered. The exhibition was opened on the 1st instant, in one of the rooms of the Leeds Fine Art Gallery, and will remain open until January 2.

By inserting this letter in your next issue you will save photographers the trouble of applying for space to exhibit, and greatly oblige yours, &c.,
Leeds, October 8, 1889.

S. A. WARRINGTON, Hon. Sec.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED :—

F. Higgins, Chard.—Three photographs of orders, medals, and relics of Admiral Viscount Nelson, Duke of Bronte, K.B. One photograph of marble bust of Admiral Viscount Nelson, Duke of Bronte, K.B.
J. Stuart, Glasgow.—Photograph entitled "Wednesday Afternoon in St. Enoch's square, Glasgow."

CYMRU.—See reply to "V. Dunn."

J. R. GOTZ.—Received. In our next.

SYNTAX.—The Photographic Exhibition closes on November 13.

V. DUNN.—We are sorry to find that any London colourist has acted in the manner described. It is clearly a case for the County Court.

T. E. G.—I. We advise you to accept the offer you have received.—2. Send the specimens to this office with an addressed wrapper for their return.

OCCASIONAL CONTRIBUTOR (Manchester).—Thanks. Send a few more, if not for publication, at least for private circulation among metropolitan photographers.

NEMO.—We should advise you to have the nine-inch focus lens in preference to the seven-inch, seeing that you already have one of six and a half inches, and of the same form too.

TRANSPARENCY.—The ornamental borders referred to for transparencies are mostly produced by the sand-blast process. Some we have seen of foreign production have been done by the aid of fluoric acid.

J. ROSS.—We do not remember your query, as we do not retain letters after they are answered. However, as you say the matter, whatever it is, is to be found in the index for last year's volume, why not refer to it yourself?

A BEGINNER.—You had better employ the pure carbonate of soda, not the bicarbonate—it is preferable to the impure article. For a five per cent. solution of pyro, half the proportion given in the usual formulae for a ten per cent. solution.

F. C. F. (Capetown).—Next to the portrait lens the "universal" is the quickest of those on your list. The next in order of rapidity of those you name is the rapid symmetrical, which, in our estimation, will answer your purpose quite well.

WM. SCOTT (Ghent).—We cannot say where there is a good opening for a first-class photographer in England. The general complaint in most towns is that there are too many there already. Certainly, competition is very keen in every large town we know.

C. BLACKWELL.—If the gelatine pellicle remains in the flaccid condition you mention, it is clear that too much—far too much—glycerine has been added. Try reducing the quantity to one-fourth. Bear in mind that only sufficient must be used to prevent brittleness of the gelatinous film. All beyond this is positively injurious.

J. S. WOODRUFF.—If for the acetate of lead you substitute three times the quantity of acetate of soda you will have a good toning bath. One ounce of the solution should be diluted with eight or ten ounces of water for use. You should bear in mind that the colour of the prints depends more upon the character of the negative than the toning bath employed.

TORBAY.—The different makers who prepare ready-sensitised papers do not publish the particular method they employ. Each maker keeps his method to himself, and to this extent the preparation is a trade secret. Possibly some of the manufacturers would teach you their process for a liberal consideration. An article on this subject is in type for the ALMANAC.

F. E.—1. The albo-carbon light with two burners and a metallic perforated shield in front is the better of the two systems described. In our volume for 1887, at page 87, you will find an article treating on this subject.—2. A good rapid doublet of four inches focus will certainly answer for enlarging, but we should give preference to the portrait objective of longer focus.

J. GASKIN WOOD.—There is very little difference between the two plates; but probably you did not use a yellow screen. Orthochromatic plates are of very little, or any, advantage without it is for copying subjects, such as that you describe. Had you employed a yellow screen you would, doubtless, have obtained a different result. Read Mr. Bothamley's lecture delivered at the recent Convention.

C. D. ROBERTSON.—Glaze about twelve feet of the roof and side, commencing, say, from about five feet at each end on the north side. The glass need not be carried up to the ridge, but about two feet six or three feet from it. With such a studio you will be able to place the sitter at either end, and so take either side of the face. The ends should certainly not be glazed. Any architect will supply you with working plans if you explain to him what is required.

OAKLEIGH.—Certainly an enlargement may be made by a single lens, but under the circumstances mentioned it will require a much longer exposure than you appear to have given. Bear in mind that the longer the negative the longer *cart. par.* must be the exposure. It is imperative that the light be well distributed over the entire surface of the negative. Should you still fail, send a drawing showing the relative position of light and negative, or, better still, call when next in town.

VITA asks:—"Will you kindly say how to prevent air bubbles from coming on silver (albumenised) prints in enamelling. I have used the gelatine bath one ounce of gelatine to twenty ounces of water, and one to ten. They come on in drying. I simply use gelatine and water. I enclose sample print."—The air bubbles do not come in the drying but arise in the manipulations. Air gets imprisoned between the print and the collodion. The only way of avoiding them is to use more care in the squeegeeing of the prints on to the glass.

A. S. RULE wishes to know if a person can prevent him from taking a photograph of his house, provided he takes it from a public thoroughfare. He says that, last week, he was about to take a photograph of a very pretty house in Hertfordshire, when the proprietor came out and forbade him doing so, at the same time threatening "to smash his apparatus and him also if he did not clear off at once."—If the photograph were taken from a public highway we know of no law to prevent it; any forcible means taken to prevent it we imagine would amount to a legal assault, and would be punishable accordingly.

CONVENER writes: "In my letter *re* late Convention in your last issue the word 'impossibility' in the second paragraph should read 'probability.' I do not know whether this was my error or your compositor's. Let me say that a word replaced by a dash towards the end of my communication was not in any sense morally unfit for publication; perhaps the printer could not decipher it. Anyhow, I am pleased to have information that the second delegate mentioned as nominated did not eventually represent the Society in question, but that, by a happy circumstance, he was replaced by a very desirable and satisfactory substitute."

FROM Mr. Arthur S. Medrington, Bold-street, Liverpool, we have received two authentic portraits of Mrs. Maybrick. Mr. Medrington says: "These are the only genuine portraits, direct from life, of Mrs. Maybrick which have been or can be published. I photographed her myself, and have been requested and authorised to publish these pictures, in order that the public may have a correct likeness, and with a view to counteract the impression produced by the photographs from wax models which have been so extensively sold as genuine portraits, but are considered to give an entirely false idea of her features."—We have never had the privilege of seeing the original, but these portraits seem as though they were excellent likenesses; they are quite unlike other alleged portraits that we have seen.

M. writes: "If your correspondent, 'W. A. Boroughs,' will get a 'George's Calorien,' sold by Farwig & Co., 36, Queen-street, Cheshire, he will be able to keep his studio warm or as hot as he likes. It must be a very cold place that cannot be warmed by one of the larger size. They can be used with gas or coke. I have had three in use, one for sixteen years, one for ten, and have one in my entrance hall—which I put in last year—to warm the whole house. The great advantage of them is that the air is perfectly pure and never smells of hot iron. The advantage of the gas ones is that you can leave them alight day and night without any fear. They never smoke or require any attention, and as my painter's studio was at the top of the house there was no coal to carry up. I should advise him to try one."

M. writes as follows: "I have been collecting my hypo residues from fixing prints and negatives in a paraffin cask, and when full put in some liver of sulphur, as per instructions in JOURNAL of February 22, 1884. The solution was black before and remains so, though I have put in at intervals one pound of liver of sulphur, so that I don't know if the residue has settled or not, and cannot see by taking out some to test. Should it be so, and how can I tell when it is settled?"—If our correspondent will test the solution according to the instructions given in the article he quotes, he should have no doubt on the subject. Had he read the articles on this topic which have appeared in our columns during the past few weeks, he need scarcely have been at the trouble of writing. Full and explicit instructions for testing the solutions are given in them.

W. M. ROBERTSON (Davos Dörli, Switzerland) puts the following queries: "1. Can wooden dishes intended for photographic purposes be coated with a varnish, such as shellac varnish, so that they will resist the action of ordinary photographic chemicals? If so, what liquid can shellac be dissolved in? I tried to dissolve it in methylated spirits of wine, but did not succeed.—2. Is there any other and better varnish than shellac?—3. Would wooden dishes covered with guttapercha be serviceable for photographic uses, and is there any special kind of guttapercha which can be used for the purpose? I have one or two wooden dishes covered with wax (paraffin), but find them disagreeable to handle.—4. What is the best material to make the worm of a small still to distil water? Is there any silver-lined tubing made for this object, and where can it be purchased?"—In reply: 1. Wooden vessels, thoroughly coated with shellac, will answer quite well. The best solvent is methylated spirit. Possibly the spirit used was too weak.—2. Shellac varnish is as good as any.—3. Yes, provided they are not used for warm solutions. Pure guttapercha must be employed. Paraffin is an excellent material and is thoroughly impervious.—4. Tin pipe (not "conno pipe") answers every purpose. If silver-plated tube be desired, it should be of copper. Messrs. Benham & Frowd, Chaudos-street, W.C., will supply a copper worm silver-plated.

WITH reference to the correspondence which has appeared relative to Lens Standards at the late Convention, Mr. William Taylor writes to say that his letter which appeared in our issue of September 27 was not intended for publication, but only written as a personal explanation of his action relative thereto, being chiefly a summary of the criticism which he made in Mr. Wollaston's presence when moving the rejection of his report, a motion supported by Messrs. Dallmeyer, Beck, and other well-known gentlemen, the rejection of the report being adopted without the utterance of a single word in favour of it. Subject to this explanation, we think it is well that the matter should have been brought before the public. A Committee was appointed in Birmingham in July last year to do certain work which would involve a good deal of time and care; but up to within a very brief period of the London gathering, no meeting of that Committee had been held. This delaying of an important measure such as that in question, and rushing it forward just at the last moment, cannot be commended; and we, with many others, are glad that attention has been directed to it by Mr. W. Taylor, although his letter, as he explains, was of a semi-private nature, and not meant for publication.

PHOTOGRAPHIC CLUB.—Wednesday, the 16th instant.—The subject for discussion: *Platinotype Printing*. Last outing of the season on Saturday, the 12th instant. Tea at the Bull and Bush, Hampstead, at five p.m.

THE editor of the *Photographic Quarterly* sends us a copy of his first number. In addition to eleven articles by Rev. T. Perkins, A. M. Rossi, Rev. W. Aston, John Hall Edwards, and others, it contains two page illustrations, one of them being a characteristic portrait of Mr. James Glaisher, F.R.S. The various articles are ably written, and the *Quarterly* is generally well got up.

WE have to record the death of Mr. William Gillard, of Gloucester, in the forty-ninth year of his age. As a photographer he occupied a prominent position, having been a successful exhibitor at many exhibitions, for which he had obtained numerous medals. His work was not only highly appreciated and patronised by the leading families in his own county, but also by those residing in places far beyond its confines.

Among the leading articles in the *New York Herald* of October 1 last, the following apology was inserted, owing to the infringement of copyright of one of Messrs. Byrne & Co.'s Royal photographs by the above newspaper:—"In the *Herald* of August 25 appeared an electrotype of the family of the Prince of Wales, which was inadvertently imitated from a copyright photograph, which, as it now appears, was originally and exclusively taken by Royal permission by Messrs. Byrne & Co., the eminent photographers, whose studios at Richmond are so well known to Londoners and tourists. The *Herald* picture was necessarily much reduced, but the original photograph and its copies are of Imperial size. The likenesses are, of course, perfect, as taken from life under peculiarly valuable circumstances, and differ artistically from the flood of photographs of the Marlborough House family, which are made up in groups from single photographs, often of themselves copies. The plate is peculiarly valuable, as presenting the Duchess of Fife in the very last photograph of her as the maiden Princess."

THE PHOTOGRAPHIC TRADE.—A meeting of gentlemen interested in the photographic trade was held at the offices of the London Chamber of Commerce, Botolph House, Eastcheap, on the 8th instant, Mr. Walter S. Bird presiding. It was unanimously agreed to form a Photographic Trade Section of the Chamber, for the purpose of advocating trade interests as apart from the scientific or amateur interests of photography. The question of copyright, it was considered, should be one of the first to be dealt with by the new section in co-operation with the Printing and Music Trades Sections, which were reported to be already dealing with their respective branches of the subject. It was also thought that the new section might co-operate with the Electrical Trade Section for the establishment of a standard of light, and also in regard to the adoption of the Whitworth screw as a means of obtaining uniformity of size. Messrs. Walter S. Bird (Autotype Company), Frank Bishop (Marion & Co.), Thomas R. Dallmeyer, Friese Greene, William Grove, H. S. Mendelssohn, L. Warnerke, S. Buchanan Wollaston, and T. P. Watson (W. Watson & Sons) were appointed a committee to undertake the organization of the section and to communicate with those firms, both in town and country, who have not already joined in the movement. The meeting then adjourned until November 4, at 5 p.m., when progress will be reported and a working committee appointed.

A BEAUTY show has just been held in London, in which prizes have been awarded on the strength of the photographs forwarded to the Judges. This plan is obviously in some respects an improvement on that which compels lady competitors to appear *in propria persona*, to present themselves as mere exhibits at a public show. Many a fair one who would utterly shrink from that vulgar form of display and all its attendant risks would be eager enough to try her luck in the photographic lottery, and all the more so that the disappointment of drawing a blank could be easily hid. But, these advantages apart, of what value can decisions be that have only, in the parlance of the dark room, "a photographic basis?" Who does not now know that the retoucher turns the world of beauty upside down, and that if he does not—sometimes cannot—improve true loveliness, he can so alter the aspect of the plainest countenance as to make it—so far as the photograph is concerned—a marvel of artistic charm. The Judges of the London show had to satisfy themselves of the identity of the prize photographs with the senders thereof, but they do not tell whether or not they convinced themselves of the truthfulness of the portraits. Is it not quite possible, at a time when the actual likeness of sitters is so liable to be "improved" away by the photographic retoucher, that some of the competitors whose photographs were cast as rubbish to the void may, after all, have been the real queens of beauty in the show? The point, however, may not be held of great account in a show which seems to have had for its supreme object the advertising of a well-known soap.—*Aberdeen Evening Gazette*.

OUR FORTHCOMING ALMANAC.—The Editor will feel obliged if those friends who purpose contributing of their practical experience, research, or experiment to the ALMANAC, and, through it, to their brethren all over the world, would kindly send their articles or hints—no matter how brief—as early as possible, as it is the intention of the publishers to go to press early next month.

We learn from the Publishers that the advertisement pages are fast filling up, and will be closed in a few days.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1537. VOL. XXXVI.—OCTOBER 18, 1889.

DANGEROUS HYPO ELIMINATORS.

AN old proverb teaches us that while one man may steal a horse with impunity, another may not venture to look over a hedge without getting into trouble. In like manner it frequently happens in photographic practice that what answers perfectly well with one operator proves disastrous in the extreme with another, simply because the small but important element of "common sense" is omitted from the formula.

How often in chemical matters a strict adherence to written instructions leads to dire failure when the necessary but unspecified ingredient, "brains, sir! brains!" is not used, perhaps no one is in a better position to know than a photographic editor. It almost seems as if one style of photographer—and he may be selected from the ranks of both amateur and professional, and from every class, educated and otherwise—lays himself out to specially discover methods of failure which would not strike the ordinary practitioner. At the same time, there are instances in which an imperfect knowledge of chemical facts rather than mere want of common sense is the cause of the trouble. What may be the true source of the difficulty in the case to which we are about to refer we leave to our readers to judge.

Within the last three days we have inspected three large albums of views, the production of an amateur who is noted for the very particular care he takes, or tries to take, in everything he does. With scarcely an exception, the whole of the prints, some three or four hundred in number, showed signs of fading; not the ordinary sulphuration commonly known as fading, but rather a bleaching action, mixed with a little of the yellowing more commonly associated with sulphur fading. Consulted as to the cause, upon inquiring into the circumstances under which the prints were produced, we had little hesitation in deciding that the very means adopted to secure their permanence had been the cause of their rapid and total destruction. That, in fact, to the injudicious or unintelligent application of what may be a really useful precaution was to be attributed the unpleasant result.

We have over and over again in these columns pointed out and tried to impress upon our readers the folly of trusting to the so-called "hypo eliminators," rather than to honest washing for the removal of the hyposulphites from fixed prints. It has been proved beyond any shadow of a doubt that it is not hyposulphite of soda, *as such*, that brings about the destruction of the photographic image, but rather injurious combinations of the decomposition products of that salt with the silver forming the image. Now, the very action of such so-called eliminators is, in the first place, to bring about the decomposition which is likely to set up the deleterious action;

and hence, as we have pointed out, eliminators should only be employed with the utmost caution, and after very thorough washing of either print or negative. We believe we are only stating what is fact in expressing the opinion that a "hypo eliminator" can only be used with *perfect safety* after a sufficient amount of washing to *thoroughly remove all hypo*; in other words, that such applications are practically useless.

The different agents employed for the purpose of course vary in their effect, some possessing a directly injurious action upon the silver image, independently of their formation or liberation of sulphur and sulphur compounds. The most harmless, or, as we should put it, the least injurious, is, perhaps, alum, which has practically no effect upon a properly washed print or negative; but the same cannot be said of peroxide of hydrogen, or eau de Javelle, Labarraque's solution, "chloride" of lime, "ozone bleach," hypochlorite of zinc, or other solutions of a similar character. These have all a powerful bleaching action, both on print and negative, and consequently present an additional danger beyond that of sulphuration.

It is now a quarter of a century since Mr. F. W. Hart first suggested the use of the hypochlorites for the purpose in question, but, if we recollect rightly, he laid particular stress on the necessity for care in the method of application in order to avoid the counter dangers. And when, about the same time, Dr. Angus Smith proposed the use of peroxide of hydrogen for the same purpose, he also directed attention to the possible danger that might arise from the remedial treatment, and practically it has been found that both with silver prints, and in more recent years with gelatine negatives, the same amount of trouble necessary for the use of the "eliminator" would, if applied in the form of fair *washing*, produce an equally permanent result without any danger.

In the case of the albums referred to as our text, the prints had all been *carefully* washed before receiving their final treatment with eau de Javelle as a final safeguard. This was applied in sufficiently dilute solution to produce no immediate bleaching action, but the mistake was made of not removing it from the prints when its work was done. Few photographers, we imagine, have not heard of the danger arising from the use of paper or mounts from which the "anti-chlor" (alias "hypo") has not been thoroughly removed by the manufacturer. If the paper maker finds it necessary for the stability of his material to "kill" or neutralise so dangerous an element as the chlorine employed in the bleaching process, it is surely scarcely judicious on the photographer's part to apply the same agent to his films without exercising the utmost care in its removal when it has served its purpose.

And what we desire to impress upon all is, that the same amount of care applied in simple washing will effect the purpose in view, the removal of the hyposulphites at least, as efficiently as any eliminator, and without danger.

ECONOMY IN THE DARK ROOM.

THE suggestion having been made that our series of articles on *Economy in the Printing Room* might be supplemented with advantage by some remarks in the same strain upon other departments, especially the dark room, we show our acquiescence by this week reviewing the work of that particular region, merely premising that as the articles already written embrace most of the subjects that would fall under that heading, anything that we say will have a tendency to be didactic. For example, we have dealt very fully, and advisedly so, with waste hypo solutions. We hear from many quarters of the immense amount of waste that takes place in this direction. Practically speaking, in those establishments where there is any attempt to collect the silver from discarded fixing solutions, the precipitation by sulphide of potassium, or "liver of sulphur," holds the field, of that there is no doubt; yet in discussing the subject last week with a firm who are amongst the largest dealers of photographic chemicals in the country, we were told that it was, comparatively speaking, quite rare to receive an order for this chemical; and we know it to be a fact that on one occasion a local chemist, who was recommending this mode of saving to a photographer using nitrate of silver very largely, was told, "Oh, yes; you would like to get an order for the stuff, would you not?" Yet with photographers everywhere crying out about low prices and reduced profits, photographers who would consider themselves utterly deficient in elementary common sense if they did not collect their print washings, it is nevertheless a fact that they daily throw away silver equal if not superior in amount to what they obtain from their print washings in serene indifference to—it cannot be said ignorance of—this most blameworthy waste! Again we urge, in the strongest manner, upon every thinking worker to collect every drop of fixing solution and extract the silver from it before throwing the liquid away. In the dark room, of all places, is this needful; for we believe that the custom is almost universal of using up the hypo till it is almost saturated with silver. This is simply false economy of the most glaring kind, for negatives are, equally with albumenised paper prints, subject to danger of fading or injury through the decomposition liable to be set up in the film by the juxtaposition of silver haloids with weak hypo solutions; and hypo solutions that were saturated to start with very quick have the attributes of weak solutions when their solvent power upon these salts is almost saturated. It is to be remembered that, to use the popular mode of expressing the action, hypo will dissolve a very small proportion of silver haloids. True economy is therefore best carried out by using fresh hypo long before it has taken up all the silver it can, and no one will have any fault to find with this item in his balance sheet if he adopts our oft-repeated advice to save his "hypo residues."

Pyrogallol is the most important chemical used in the dark room, and economy in its use cannot be treated in any very varied manner; but when we have seen a large array of empty pyro bottles stowed away in some corner in this department, we have more than once asked why it was not bought in bulk? "The trouble and bother of weighing," is the usual reply. We suppose that because it weighs light it is thought difficult. We

need scarcely say that such is not really the case. Yet, to avoid this imagined difficulty, photographers who use pounds weight in a year pay something like a penny an ounce—for such in effect is what they do when, as is usual, the empty bottles are not utilised—or about ten per cent. upon its cost to be rid of the trouble of weighing. We do not hear of such a sum being paid to avoid having to weigh acetate of soda, or nitrate of silver, or "hypo" crystals, and it is really absurd to throw money away over this particular chemical.

There is, however, much to be said for pyro economy in another direction, using the same solutions several times over. We have some time ago narrated experiences in this way, and have seen developer used over and over again with advantage. When a few negatives only are dealt with, it is really not worth the trouble of storing away once-used solution; but when negatives in large quantities are developed at once, considerable saving in this way may be made. We have lately tried some experiments in this way, and have found that the same solution may be used three times over with little disadvantage. The second plate passed through differs little from the first; but the third has a decided yellowness of colour, which is still increased when the fourth plate has passed through. We should of our own experience be inclined to fix upon three as the maximum number of times a solution may be used when extreme yellowness is objected to in the colour of the negatives. Much depends, of course, upon the thickness of the film as regards the number of plates to be passed through, for the thicker the film the greater the liability for it to become quickly yellowed. Much also depends upon the proportion of sulphite of soda employed, and its use now is very common, notwithstanding the objections to its use so strongly brought before photographers a few years ago. There is a distinct difference in the extent of the yellowing to be perceived in the finished negative according to whether the proportion of two, three, four, or even five ounces to one ounce of "pyro" be adopted. Four ounces was originally recommended by the inventor of the process; but we find a distinct gain to accrue from using the largest of these proportions, namely, one ounce "pyro," five ounces sulphite. It will be found that the extra one ounce leads to very increased "staying power" in the solution, which, even after the third negative has passed through, is still by no means very dark in colour, and is far less likely to engender bubbles in the liquid, these having a particularly unpleasant way of attaching themselves very firmly to the film.

It will, we think, be interesting to our readers to know the practice of a brother photographer who has a large connexion and orders chemicals in quantity. We therefore conclude the present article by publishing the formula he adopts for his pyro stock solution. It is simply:—

"Pyro"	1 pound.
Recrystallised sulphite of soda	5 pounds.
Citric acid	$\frac{1}{4}$ ounce.
Water (if boiled all the better)	2 gallons.

This solution will keep for months (if not years), and will stand a considerable amount of careless storage without becoming discoloured.

AN admirable opportunity is now afforded those who desire to see the collated works of Mr. H. P. Robinson, these being at present on exhibition in the Camera Club, to which any one may for this purpose have access on presentation of his card. Here the old time-honoured productions of this clever artist are to be seen adorning the walls. His *Bringing Home the May*, *Fading Away*, the *Lady of*

Shalot, and, indeed, all his work, including his last picture—*Merry Fisher Maidens*, now in the Pall Mall Exhibition—are to be found. Their perusal cannot fail to interest and instruct. All who possibly can should see them.

THE interesting specimens shown by Mr. Levy in illustration of his experiments communicated to the Photographic Club last week, an account of which will be found on another page, are at present in our possession, and for the next two or three days may be seen on application at our office. Thereafter they will be restored to the archives of the Club. Mr. Levy's experiments are of great value, and the specimens entirely bear out all that he says.

If proof were wanting of the rapid spread of photography, it is furnished in the multitude of new societies which are springing up in every direction, and the number of members that are enrolled, as well as the interest taken in the meetings. Take, for example, the West London Photographic Society, which is not yet a year old, and it numbers about eighty members, as we see by its report. But this is by no means exceptional. What is more, in these new societies the members attend and take a lively interest in the meetings. If some of the older societies' meetings, say those of the Parent Society, for instance, were as, proportionately, well attended as most of the younger ones are, their present premises would prove somewhat inconveniently small.

THE numerical strength of any society must not be taken as a criterion of its vitality. This can only be judged of by the attendance and discussion at the meetings. A society may be composed of several hundred members, yet if only a score or so interest themselves in its meetings it indicates a moribund condition. The old North London Photographic Association was a case in point. At the time of its demise, now many years ago, it had, if we remember rightly, somewhere about 120 paying members; still, it used to be considered a good meeting when even less than twenty attended. We direct attention to this subject as a hint to Committees and Secretaries of new societies to keep up a good *pabulum* for their meetings.

THE country, at the present time, is in a glorious condition for photography, though the weather for it may, just now, be a little uncertain for outdoor work. The autumnal tints, as now seen, render the landscape exceedingly charming. Although the recent gales may have, in some parts, thinned the leaves a little, it will make no practical difference in the picture. Indeed, in some cases it is an improvement rather than otherwise, as the foliage being somewhat thin gives an enhanced autumnal effect. A considerable advantage will often accrue at this time of year in landscape photography from the use of orthochromatised plates, provided they be used with a pale yellow screen and with discretion generally; because the great variety of tints which in most places now exist, and add such a charm to nature, will be the better rendered in the photograph. The plates for the purpose should be specially sensitised for the red rays, say, by the addition of cyanine to the usual eosine orthochromatising mixture. At this season natural clouds can generally be secured with the landscape—an immense advantage pictorially.

Do photographers—that is, professional photographers—care sufficiently as to whether their pictures are permanent or not, or as to how soon they may pass into the sere and yellow stage? There can be no question that the silver prints sent out at the present day are not so permanent, as a rule, as those which were issued from the same establishments, say, fifteen or twenty years back, notwithstanding that as much care is said to be bestowed upon their production. Various reasons are assigned for this, such as lightly sensitised paper, thin negatives, deleterious mounts, &c., or perhaps a combination of the whole. Be the cause what it may, the fact is incontestable. Although photography has made such rapid strides during the past quarter of a century, yet, so far as the permanence of silver prints is concerned, it has certainly retrograded. It is no unusual circumstance to see pictures, for which from one to two

guineas per dozen was paid, to show unmistakable signs of fading during the first year or so—sometimes even within a few months, while others, twenty years old, are in a far better condition. Surely the public have the right to expect the same degree of permanence in their photographs now, with all the vaunted advances in the art, as they used to get when photography was yet in its infancy.

THE above suggests a question which will, doubtless, arise some day. It is this: Would an action at law lie against a photographer for the recovery of the amount paid for photographs which had faded in an unduly short period? If it did, it would prove exceedingly unpleasant for many large firms—and small ones, too, for that matter. It might be pleaded that it is a recognised fact that silver prints do fade in time; but that would hardly avail when they go within a few months, while others, after twenty or more years, are still intact. It might well be argued that if produced under similar conditions all pictures ought to be equally permanent.

SCARCELY a week passes that we do not receive a number of letters from correspondents—amateur photographers—on the subject of toning. The most general complaint is that the prints, after being in the bath sometimes for an hour or more, still remain red, and when fixed change to a dirty brown or grey colour. Almost invariably the letters terminate with a request for a "good formula for a toning bath for rich purple or black tones," as if this were all that was required to secure the desired colours. This week the letters received on this topic exceed the usual average, and the examples enclosed, in every case, show an entire misconception on the subject of toning generally. For example the print has usually been utterly ruined by over-toning, although the fault has generally been attributed to the bath employed. Few beginners appear to realise the fact that the trouble in obtaining deep tones may be, and in the cases now before us are, due either to the manipulations or the paper, but principally to the negatives themselves.

WE have frequently pointed out that the particular toning bath employed has very little influence upon the colour of the print. This depends almost, if not entirely, upon the negative and the paper used. With a suitable negative and paper, identical tones, from a red-brown to a deep purple or black, may be obtained by almost every toning bath now in use. But unless these conditions are fulfilled, no special formula will help matters to any material extent. With a feeble negative—one lacking in contrasts—it will be impossible to obtain deep, rich tones, no matter what toning solution or paper be employed. It is true that some papers will stand more toning than others, but none to the purple stage unless the negative is a vigorous one. But with a suitable negative and most of the commercial papers, almost any tone desired may be obtained, and that, too, with nearly every kind of toning bath. Some papers, however, there are which even with a strong negative will not tone beyond the warm stage, and if the prints be left in the solution too long they will, when finished, be cold and flat, mealy, and without vigour, though if they were removed at an earlier stage good prints of a warm tone would be secured. This remark applies with equal force to prints from feeble negatives on whatever paper that may be used. Few negatives nowadays are so feeble that they will not yield fairly good impressions if the toning is not carried beyond the warm stage. When the zenith of tone any print will take is reached, any further action is one of degradation. This point should be borne in mind by the inexperienced, who appear to imagine that the colour of the print is entirely dependent upon the particular toning bath employed.

OPAL pictures of the scrap type, we are given to understand, will be more extensively utilised as "Christmas and New Year's Cards" this winter than hitherto. Many provincial photographers might, we surmise, materially increase their returns during the dull season by issuing photographs of picturesque local scenery on opal glass, with suitable seasonable greetings inscribed thereon, and neatly mounted. The inscription might be written ornamentally on the negative so as to appear white in the finished picture. Such pictures would, no doubt,

sell well at a fair price, and at such would yield a good profit; that is, if we may judge from the price at which the cheap opals sold at the stationers are now being produced.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—III.

In resuming our remarks upon the pictorial aspect of the Exhibition, we will first notice those pictures which were precluded from competition by their producers being elected as Judges of Awards.

George Davison (Nos. 7 to 13).—A series of well-studied pictorial bits of nature, some having figures introduced with much care. The chosen positions of these figures indicate a thoughtful attention to their capabilities of assisting the composition by form and depth of tone. In some of these studies there is a total absence of those very light renderings which so often will assert themselves in the immediate foreground. In No. 10, *Albury Heath*, it would appear as if the negative had been left to its normal condition, and the usual result had taken place; but in others—especially Nos. 11 and 12—the foreground is made to appear very deep in tone, the treatment in all cases is very effective, and at once reveals an artistic perception of what to do and what to leave undone; but the question arises how this has been produced—is it possible to have carefully toned down certain parts of the print after it had left the negative? In No. 11 this subjection of foreground increases in depth of tone to the lower portion of the print, and so suggests the surmise. Such treatment is absolutely the first step towards combination printing. However this may be, the result is very good, and the whole seven pictures show a well-directed artistic faculty, from which the great army of photographic picture makers should receive most valuable lessons.

F. Gale (Nos. 38 to 41).—Four small studies by this most artistic photographer, whose choice of subject-matter to act as the harmony to the melody of his figures is now looked for at each succeeding Exhibition; and although these pictures are not quite up to his standard of excellence, yet they show most careful attention to form and selection of dark and light portions, which not only satisfy the artist, but which also arrest the attention of the ordinary admirer of pictorial work.

H. P. Robinson (No. 65), *Merry Fisher Maidens*.—This is one of those composition photographs about which so much literary talk is now being expended; and apart from the purely scientific right and wrong of these productions, we can only remark upon such work from the artistic side, and that is, how far can photography be made the medium for the production of pictures in which art supplements the scientific operations? Leaving this warfare which is agitating the army of material purists, we can only discourse upon the productions before us; and whilst there is much, very much, in this pictorial outcome which shows the master—and of whom it must also be stated that he ranks very high amongst those who strive to raise photography to the possibility of fine art where *facsimiles* are not the sole object of reproduction—at the same time, there are some few points to which exception might be made; but the conception and realisation of pictorial subjects, by means of tools so much of which is automatic, must always make the productions of this exhibitor go far away beyond the ordinary attempts of others, unless they also possess and cultivate the artistic faculty.

W. Bedford (Nos. 271 and 284), *Ludlow Castle*.—Two views of this romantic spot, where the castle is made subservient to the study of foliage, of which there is much in these two frames. This treatment of the subject involves a study of form and detail which conveys an accurate representation of the local surroundings; all this has been treated in a very judicious and masterly way, the result being a most accurate rendering of this very picturesque locality.

David R. Clarke, M.A. (No. 98), *The Way of the World*.—A picture of the courtship of two members of the working classes. The photographic work of this exhibit is very good, but the composition might have been considerably improved if the standing figure of the man had not been quite so straight; again, on the opposite side of the picture there is a square black mass of nothing, which weighs down the effect to a very commonplace result. Notwithstanding

these points, there are evidences of a desire to produce a picture which is really very good, considering the nature of the models. Therefore we notice this work in detail, with the anticipation that at some future time far better pictures will be forthcoming.

A. Horsley Hinton (Nos. 113 to 117).—A series of five photographic studies of old tree-stems, &c., which are exceedingly good specimens of careful and studied attention to the working of the machinery by which is recorded facts and detail of a very complicated order, which these pictures so clearly show. There is a charm about the quality of these specimens of careful and very clear work which is very pleasant to look at, and they bring us back to the real outcome of photographic work, which is exquisite detail associated with well-balanced light and shade.

School of Military Engineering (No. 120), *Ickley Wood*.—Two pictures in one frame, which are very good examples of the work of these clever engineers. These copies have been printed very deeply in order to secure a powerful effect, but sometimes the gain of richness in one part is overpowered by the blotting out of detail in another, and a general overcast of very dark bits is the result; otherwise the choice of subject and general effect is very good. A closer attention to the possibilities of unlighted or locally deep-toned portions not yielding to chemical action, and thereby becoming plague-spots, as also the unreality of such black masses, would have made these pictures much more suggestive of really very good work.

Francis Cobb (Nos. 134 and 135).—Two pictures of country places and picturesque buildings, both treated from a well-considered point of view. Here again the characteristic mark of photography, viz., its capacity to show detail, has been well made use of, and presents us with matter which, when well chosen, as in these pictures, affords much pleasure. The figures in No. 134 would have been more effective if they could have been placed nearer the centre; and again, the same cloud negative being printed in both pictures, however effective and possible to a certain extent, yet is open to objection when the two photographs are hung together; a fate which they undoubtedly deserve.

Rev. F. C. Lambert (No. 171), *A Labour of Love*.—Another of those pictures where the aiming pictorially at sentiment by photographic means seems to be so much in vogue at the present moment. Considerable attention has been given to the composition of this group of the two sexes, but the question arises, Is it worth while recording so much of every-day life from the realistic point of view? The mission of art should be to poetise the ordinary by judicious posing of models and combination of form; and why should photography, which records anything placed in its way, be subjected to so much of literal work? We throw out these remarks because any one who shows the slightest disposition to utilise science for the production of art work must progress; it is only the way that requires to be clearly pointed out. There is so much thought and care evinced in the treatment of this picture, that we make these remarks with a desire to raise photographic art to a still higher status.

S. Bourne (Nos. 185, 186, 187), Three small photographs of pretty bits of landscape. There are eleven pictures hung consecutively; but these three are the best. At the same time, the subject-matter would have better suited a larger size, where the detail would be more conspicuous.

Captain Abney, C.B., R.E., F.R.S. (Nos. 250 to 257), *Views in Switzerland*.—These photographs convey a most interesting idea of the locality, more so than when bits only of mountains are shown; for here we realise what the locality is like. But these photographs being small hardly do full justice to the scenes. They are a little too delicate in treatment, and consequently suggest prettiness rather than grandeur.

John J. Thornton (No. 261), *Off We Go*.—Some boys with a boat are just releasing it from its fixed position, and we can imagine the rest. The arrangement of the effect is very good, and the treatment of the position of the figures tells the story very clearly. This photograph promises much for any future work treated in so clear a manner.

Henry Stevens (No. 270), *Flower and other Studies*.—A frame of eight prints, six of which are flowers, which still maintain the even but very successful attributes of this careful student of a most difficult study, where the combination of light objects, such as the

vases and the almost white floral beauties, results in very pleasing and attractive pictures; but we miss those much larger specimens of his skill in this particular work which formerly gave more scope for composition and pictorial effect.

W. J. Byrne (No. 301), *At Home Portraits*.—Here we have a frame of fifteen portraits taken at the residences of the sitters, amongst whom is one of the Princess of Wales, apparently walking up a staircase. This one photograph is very interesting, as it so completely realises the home of a noble lady, who apparently has been photographed whilst ascending the stairs in a most natural and effective position. It would have been almost impossible to have procured such a picture in the studio; and the same thought applies to all the other noble and high-bred sitters who fill up the large amount of similar studies. Apparently, there are difficulties which arise under these conditions; but the more important and valuable fact looms out, viz., the utter absence of the ordinary conventionality of studio accessories. The series lose much of their value by being all arranged close together in one frame, and would have been much improved if about half the number had been allowed wider expanse in the mount.

W. W. Winter (Nos. 312 and 327), *Portraits of Ladies*.—These are large direct portraits taken apparently upon 24×20 plates, and are very good studies, the charm of which arises from plain backgrounds having been used in each picture. There is some very effective lighting in both these exhibits, which would have been very much increased if those dreadful white mounts had not been used. In all pictorial subjects the principal matter, which in these cases are the faces, should be kept prominent by the tone of the frame or mount, and where several of such mounts come together, the effect is not only disastrous to the portrait, but disturbs the vision of the looker on. There are plenty of examples in this year's Exhibition which clearly evidence the correctness of these remarks.

Gambier Bolton (Nos. 351), *Lion Study*.—A very fine photograph of the king of beasts, where the pose of the head and forelegs is most effective. The treatment of the negative has also been in complete accord with local gradation of colour, and much praise is due to the photographer for so careful a study of a most difficult subject.

W. Wainwright (No. 350), *English Scenery*.—There are five views in this frame and an interior to evidence the work of this exhibitor, who does not appear quite so happy this year in the choice of his points of view; and most certainly it would have helped the effect if more detail had been effected in many parts. There is evidence of much thought and design in the position of the figures and accessories, but so many portions of the trees and foliage have so little detail that an injustice is thereby done to the otherwise artistic study which has been given these exhibits.

O. Essenhigh Corke (No. 400), *Knowle House*.—Four views of the interior show a good rendering of difficult work in rooms filled with old furniture, where by the carefully attended disposition of some articles of furniture an effect has been realised which is very satisfactory, as showing a desire to depart from the house-keeper's views of proper positions, and some very interesting photographs have been the result.

THE APPARATUS.

The "Giah," a camera of the *genus* detective or hand, exhibited by Messrs. Mawson & Swan, claims special notice. At first sight its construction and its appellation seem fittingly adapted one to the other, the former being seemingly complex, and the latter somewhat mysterious. Doubt respecting the name is allayed when we are informed that "Giah" is merely the Welsh for Winter, Mr. Winter, the active London representative of the firm mentioned, being at once the inventor and a native of the principality. Let us hope that there will be a limit to this kind of nomenclature, else will the Gaelic, the Erse, and the vernaculars of Indian and other tribes and nationalities be imported to the exclusion of the well-worn Greek. The general idea in the Giah is this: In all cameras there is an unused space between the lens and the sensitive plate, both above and below that angular line which connects them, and why not utilise this space by having a reserve of sensitive plates above and of exposed plates below? The mechanical problem to be solved is the

transferring of a plate from the reservoir of the unexposed to the exposing position, and then removing it to the reservoir below prepared to receive it.

The unexposed plates are placed horizontally, film downwards, in the twelve upper grooves of a square lift, there being twelve similar grooves provided in the lower portion of the same lift for the reception of the plates after exposure. A rotary slide is provided having two grooves, which are parallel and duplicates of each other. When the lift of grooves is at the top the upper groove in the rotary slide, containing the unexposed plates, is exactly opposite the lowest groove, and the first plate is free to slide into it by slightly tilting the whole apparatus. A quarter turn backwards of the rotary slide carries the first plate into a vertical position, film forward, for exposure, after which another quarter turn in the same direction carries the plate into a horizontal position, film upwards. A slight tilt forwards will now cause the exposed plate to slide into the first of the lower set of grooves in the lift. The duplicate groove of the rotary slide is now in the same position as was at first occupied by the other, and is ready to receive the next plate, and the same set of movements are repeated. In order that the lift may be lowered, so that the grooves therein may come successively opposite to the grooves in the rotary slide, the two are geared together by a rack and pinion movement, and after all, or part, of the plates have been exposed, the lift is returned to its first position by simply turning the rotary slide in the opposite direction.

The lens, which may be of any suitable character, is carried in a closed tube or tunnel, which is placed in the space left between the unexposed plates at the top and the exposed plates at the bottom of the lift. Means are also provided to prevent the return of the plate after tilting; to press the plate gently up to register during exposure; to indicate on the outside the number of the plate in position; to facilitate the stopping of the rotary slide accurately at the quarter turns, as required; and what is the most important point, to ensure that the grooves in the lift and the rotary slide respectively are brought exactly into line with each other at each half turn. And should any doubt exist as to the position of the plates, small ruby windows are provided under cover, so that the operator may at any time satisfy himself on the point. All the movements are automatic and simple. The operator has only to turn the rotary slide backwards—one-quarter turn each time—and the plates, without backing or sheathes, are carried into the exact position for exposure, and afterwards stored up. At no time are they exposed to any light excepting during exposure; the films cannot be injured, and the plates may be changed in bright sunlight without the slightest danger.

As one of the chief points in hand cameras is unobtrusiveness, the case is so constructed that nothing of a noticeable character is seen. And further, an experienced observer would fail to decide that the neatly covered box was a camera, mainly because the lens hole is hidden. This is done by what appears to be a strap (connecting with the carrying handle), which apparently runs right round the case, covering up the lens. A portion of this strap is, however, an imitation only, and is in reality a metal strip, covered with leather and pivoted on the same axis as the circular disc which forms the real shutter on the inside. By turning this imitation strap to the right slightly over a half turn it remains in a vertical position, and the shutter is set. The lens hole is still covered. On liberating the shutter the strap flies round to its normal position, carrying the shutter with it. The lens is not uncovered during the setting of the shutter, and the speed is readily adjusted by a suitable index finger on the bottom of the case.

The exhibits of Mr. J. R. Gotz are so carefully enclosed in a glass case as to preclude their being handled or examined. But as we have been privileged to examine most of them under more favourable circumstances, we are enabled the better to speak of them. The collection of Suter's lenses, with the English agency for which Mr. Gotz has been inseparably connected since their inception, has this year made somewhat of a new departure, inasmuch as the time-honoured flint and crown glass of hygone times, of which photographic lenses have been made, have in this instance been made to some extent to "take a back seat" and give way to the glass more recently obtained from Jena, by which old ideas respecting refraction, dispersion, and spectral irrationality have been revolutionised. As we have said on a former occasion, the judicious employment of this glass in photographic

objectives extends the area of sharp definition to a greater distance from the centre of the field of delineation, thus flattening the field with a larger aperture than heretofore.

THE WHOLE DUTY OF THE PHOTOGRAPHER.

II.

AFTER the photography of man and the making of type portraits of human beings as they are at present, I reckon next in importance to be the recording of the way men work. In this the photographer may find much exercise for his ingenuity; nothing should be beneath his notice—attitude while working, clothes, tools, and all surroundings should pass before the impartial lens; but of this more under the second and higher function of the photographer.

Thirdly, beasts and their ways of life are of no small interest, and the biologist of the present day would be well pleased to have any sort of information as to the form and appearance of our familiar domestic animals a few centuries ago, in order to measure the rate of their variation. As it is, he has to do without these data, but there is no reason why the evolutionist of the future should not be better off.

Many other living things should be photographed to scale, in order to estimate their rate of increase—as an instance, lichens. There is a story of a French savant, who, when a little boy, climbed on to the roof of his father's house, and there, in pure idleness, chipped with his knife a ring round a spot of lichen on the slate. Fifty years after he chanced to be again on the same housetop, and there were both the ring and the lichen, scarcely changed in half a century. From this, and a few other isolated observations, we know that these lowliest of created things, soft-fingered and delicate as they are, can eat into the hardest rocks and outlast the forest trees. Measurements of the exact rate of their growth and change are still wanting, so far as I know—to our shame be it said. I would propose that a measuring line, with clear and accurate graduations, should be laid across patches of lichen on stones, and large-scale photographs made of these every year, or every ten years, till some definite knowledge is arrived at. This is an isolated instance, but any number of similar applications could be thought of, none of them, perhaps, worth attempting by any individual, but well worthy of the attention of a society of longer life than that allotted to man.

Accurate pictures indicating the size and form of the flowers of the present day would have, in the future, the same sort of value that those of beasts will possess.

Fourthly, the perpetuation of the present aspect of buildings and natural objects is a function of no small importance. Let it not be forgotten that stones and lime do not last for ever, nor are the rocks eternal—all things change, and at this time a large and increasing section of the scientific community is engaged in investigating the rate and conditions of these changes. It rests with the photographers of to-day to place this study on a sure basis of exact knowledge.

This is a slight and superficial indication of the nature of the trust which at present rests in the hands of us photographers. The task is not a light one, but we are a numerous and rapidly increasing body, and it is by no means beyond our powers.

For the preservation of these records when made, I say they ought to be inserted in great albums, sacred from the polluting touch of the silver print, kept with care by the Royal Photographic Society of the future. Such a society would have, as one of its highest and most trusted officials, a keeper of the albums, on whom would devolve the responsibility of choosing photographs and seeing them mounted and fully labelled with every precaution for their preservation.

To fill such albums, it would only be necessary to let it be widely known that permanent prints of the kinds I have spoken of were wanted to produce a supply far exceeding the capacity of any albums ever dreamt of.

A very interesting class of portraits which ought to be preserved for future use exists in the photographs of criminals taken at the various convict prisons throughout the land. I have seen many hundreds of these, and they were very interesting as a study of the physiognomy of every sort of human degradation, although the most prevailing characteristic was an amazing stupidity. All the photographs of this sort that I have seen were bad silver prints, and most of them were already far on their way to oblivion.

As to such albums lasting till they became of inestimable scientific and social value let there be no anxiety, paper is more enduring than bronze. Have we not little books on common paper four or five centuries old, and others of parchment of ages exceeding a thousand years? Pending the formation of the R. P. S., why should not the Camera Club give evidence of its public spirit by beginning such a

collection as I have spoken of on the understanding that the albums would be taken over by the larger society as soon as possible?

Although I have written thus far about things which photographers might do, and which they either neglect entirely or perform insufficiently, it must not for a moment be supposed that I accuse my brethren or myself of leaving undone *all* those things which we ought to have done. Far from it; scarcely a day passes without our hearing of some new and ingenious application of photography to the service of man or of science. This is as it should be, but as I honour the craft, so I would have it be in all things worthy, and that is why I insist that it should still be of so much greater utility.

That photography is not more widely applied is often due to ignorance on the part of those who ought to know better. Scientists are only now beginning to recognise that in the sensitive surface they have an eye which can simultaneously see and truthfully record whatever is properly presented to it, and can, moreover, see many things which really exist, although not discoverable by the unaided human vision. Though the solar spectrum to the eye includes only a short band of seven colours, by properly contrived instruments it can be shown to continue for, probably, at least ten times its visible length in each direction, and all this may be seen and investigated with great accuracy by means of sufficiently sensitive surfaces. For investigating the rays beyond the red end of the spectrum a surface sensitive to heat is required, and although Captain Abney did succeed some years ago in preparing plates sensitive to the rays from a boiling kettle, I am not aware that photography has in many cases replaced the thermopyle, though its advantages would be great if plates could be readily prepared sufficiently sensitive to the red rays. For the investigation of the spectrum beyond the visible violet there are no methods known except those depending on photography, which has been applied with considerable diligence. One recent and curious result of this application is the discovery that the description of liquids as coloured or colourless requires to be modified, because many liquids which allow all the visible spectrum to pass through them, and which we, therefore, call colourless, exhibit broad and remarkable absorption bands in the ultra-red or ultra-violet, so that we may say that these liquids possess characteristic colours, only our eyes are unable to see them.

It is unnecessary here to enumerate all the multifarious ways in which photographers serve almost every science known to man, suffice it that I consider that it speaks very highly for the energy and ingenuity which have been turned in that direction during the past fifty years that photography is now recognised, not only as the handmaid of the sciences, but as a science by itself well worthy of study.

Cosmo I. BURTON.

COLOURED PHOTOGRAPHS.

X.

THE *yellow* family is a large one, and although we gave it considerable attention in our last paper, there are still many members which must receive our consideration. I hope none of my readers are losing patience and wishing both me and my analysis at an untimely end. I fear this analysis may be considered somewhat like physis, not cared for by the generality; nevertheless it is good for us, and we must imbibe it. To acquire a thorough knowledge of anything requires a good appetite, and to those who have such, with the addition of a good digestion, I hope these papers, while on this particular stage, will not be considered as over-large doses. In our last we finished with *Mar's yellow*, and having fully considered this we come next to—

Roman Ochre.—This pigment is similar to yellow ochre in many ways, in its origin and in its durability, as well as a strong resemblance in colour. It is made from a native earth coloured by sesquioxide of iron. As I said, it is somewhat similar in colour to yellow ochre, but possesses less of the orange hue; it is likewise more transparent, and consequently for many purposes is very often preferred.

Brown Ochre.—This colour is similar both in its composition and properties to yellow ochre and Roman ochre, but differs considerably in its hue, being a rather deep-toned, brownish yellow. This colour is much valued by artists for its density. Like the other ochres it rejoices in a good reputation for durability, but this is somewhat qualified by the suspicion of its being likely to *injure* somewhat delicate colours. By the latter I mean not so much the apparently delicate, but those constitutionally so.

Yellow Carmine.—This pigment is a very rich, powerful, and transparent colour, and is the first of a set of three lakes prepared by the precipitation of the colouring matter of quercitron bark in combination with alumina. It sometimes appears under the name of *yellow madder*, but this must not mislead you, although it is somewhat calculated to

do so. Naturally the substitution of *madder* in the place of *carmine* suggests the possession of a greater amount of permanence, but it is altogether presumptive, and consequently more than likely to deceive. Its lack of the quality of permanence is more than an ordinary regret, as it is a most beautiful colour and forms a most admirable *glaze*, but its use is absolutely fruitless. It is extremely evanescent under the mild influence of the most ordinary daylight, but a very short exposure indeed to bright sunlight will cause its total disappearance.

Italian Pink.—This colour in its composition is very similar to yellow carmine. It contains rather more alumina and less colouring matter, and is, as a natural consequence, less rich and powerful. In all its other qualities it may be considered as absolutely the same, being second of the set.

Yellow Lake.—We may consider this colour as the third of this set of lakes. It is, if anything, a still weaker preparation. It bears a very strong family resemblance to Italian pink, but in hue is somewhat more lemon.

Gallstone.—With this colour we may consider our list of yellows complete. Although it is the last, however, it is not *lasting*. The real gallstone is an extremely rich, deep-toned, and gorgeous yellow, but, like all such things so beautiful, is doomed to fade. It is most fugitive, so much so indeed, that it does not merit attention except as a warning lest we should unthinkingly use it. Exposure to light will soon destroy it. It is not easy to procure in large quantities, and consequently a substitute is often found to do duty for it, which is nothing more or less than our fickle friend, yellow carmine. The pigment is prepared from a calculus found in the gall-bladder of oxen.

The next set of colours to suggest itself to us is that of the *green* pigments. In this we find oxide of chromium, viridian, emerald green, Hooker's green, Prussian green, sap green, and terre verte.

Oxide of Chromium.—This pigment is a rather cold, sober (if I may be allowed the term), sage green. It is possessed of great depth of tone, and is opaque. Although dull in tone as suggested, its quality of colour is most agreeable. It mixes well with Chinese white, and the tints thus produced are most pleasing and grateful to the eye. Oxide of chromium would make a bad laundress, as it washes somewhat indifferently. I would recommend its use *sparingly*, as being a very dense and powerful colour its too frequent employment would be likely to result in a considerable heaviness of effect.

Oxide of chromium is prepared artificially by a dry process, and consists of the anhydrous sesquioxide. As to its permanence there is no doubt—we may look upon it as one of the most permanent pigments we possess.

Viridian.—This colour is often known as *French Veronese green*: it is a bluish-green possessing very considerable depth of colour. In its paler washes no colour can surpass it for clearness, and, generally speaking, there is no mixture of the ordinary blues and yellows which will produce at once a green so beautiful and durable.

Viridian differs from oxide of chromium inasmuch as it is a hydrated instead of an anhydrous sesquioxide of chromium, and also in its being transparent, whereas the latter is opaque. It is possessed of extreme permanence.

Emerald Green.—This is a most vivid colour, and wherever its use is necessary there is no combination of blue and yellow that can be made to do successful service as a substitute. It is rather difficult to work, and it must never be used in combination with any of the yellows of the cadmium family. Emerald green is not easily affected by exposure to light, but has an undoubted tendency to become darker in tone if submitted to the influence of an impure atmosphere. It is made of aceto-arsenite of copper prepared by a process of precipitation, and I think, everything considered, may be looked upon as the most durable of all the greens having a copper base.

Hooker's Green.—This colour may be said to be a mixed pigment, inasmuch as it is produced by an intimate combination of gamboge and Prussian blue. In use it is a very transparent and serviceable colour. There are two preparations of this colour, known as Hooker's green, No. 1, and Hooker's green, No. 2; and, of course, they differ considerably in hue. Hooker's green, in both hues, is possessed of that degree of permanence which we might expect it to have when we remember its constituent parts.

Prussian Green.—This colour, like Hooker's green, is also a mixed pigment, being a mixture of gamboge and Prussian blue, but with a very considerable excess of the latter pigment. It is consequently a very bluish-green and possessed of great depth and transparency. As in the case of Hooker's green, no more reliance can be placed upon it, as regards its permanence, than can upon its constituent parts. The most, therefore, we can say upon this score is that it is not more fugitive than gamboge or Prussian. This recommendation must, therefore, be taken for what it is worth.

Sap Green.—This pigment is an extremely transparent yellowish

green. As a colour I admire it greatly, but its reputation, I am sorry to say, will not stand investigation. This colour was originally a vegetable pigment, prepared from the juice of buckthorn berries, which, in addition to its unquestionably being fugitive, was also hygroscopic, and, as a natural consequence, likely to become mildewed. This preparation is not often to be met with now. The pigment at present to be bought as sap green is nothing more or less than an imitative green lake prepared from yellow lake and Prussian blue. This colour is mostly valued by the flower painter. Sap green is a most ineligible pigment, its beauty notwithstanding, owing to its lack of durability. It will not resist a lengthened exposure even to ordinary daylight.

Terre Verte.—This is one of the oldest pigments in existence. It is semi-transparent, and can be mixed without fear with other colours. It is a natural earth of a quiet bluish-green hue, its colour being derived from the presence of protoxide of iron. Like all colours of similar base, it is not a very bright or powerful pigment, but is a very durable one.

We have now come, safely I hope, to the end of the family of green pigments, and the next in natural order will be the blues. I do not wish my readers to have these, although the occasion may be somewhat propitious. Under this heading must be classed, for our immediate consideration, new blue, cerulean blue, Antwerp blue, Leitch's blue, and intense blue. Of course there are more blues than these, but we have already entered into their merits and demerits, and need only here mention their names *en passant*, viz., genuine ultramarine, French blue, cobalt blue, smalt, Prussian blue, and indigo. The first, therefore, to claim our attention is—

New Blue.—This colour is merely a pale variety of French ultramarine, and possessed exactly of the same qualities and properties. It may also be regarded as a rather good, and certainly inexpensive substitute for that beautiful and useful colour, cobalt.

Cerulean Blue.—This pigment, sometimes called *Ceruleum*, is a compound of the oxides of tin and cobalt, artificially prepared by a dry process. It is a comparatively modern pigment, and there is a vast difference to be found in the various manufactures of it, and great care should be taken to secure a really good one. It is possessed of a peculiar quality—of not appearing the same in hue by daylight and artificial light. By the former it may be described as a light greenish-grey blue, with but little depth or richness of colour. By the latter, peculiarly enough, it appears to be a fairly pure blue, tending neither to the green on one side, nor to purple on the other. In all other respects I do not think that cerulean blue possesses any very striking qualities. I have not found it over pleasant working, great caution being required when using it to avoid producing a chalky effect. I have always, too, found it work very indifferently.

Cerulean blue, as regards permanence, has rather a very good reputation, as it is considered well able to stand all exposure to light, but, like cobalt, an impure atmosphere will considerably affect it, and ultimately cause it to discolour. I consider it a far more useful colour to the scene painter, for whom all its qualities are more suitable, than the ordinary artist.

Antwerp Blue.—This pigment may be looked upon as a paler and at the same time less permanent variety of Prussian blue, and contains a rather large quantity of alumina.

Leitch's Blue.—Sometimes known as *Cyanine blue*, is simply a skilful combination of cobalt blue and Prussian blue, and possessing, as regards endurance, the properties and qualities which we might fairly expect to find in an admixture of these two pigments. Experiments have shown this colour to be very durable under rather severe exposure to strong light.

Intense Blue.—This pigment is simply indigo refined down by solution and re-precipitation. Many are of opinion that by this means it is rendered much more durable. On this point, at the moment, I do not feel disposed to give an opinion; but there is no doubt whatever that it is rendered much deeper and more powerful. In all other qualities it is similar to indigo, but possesses the rather unfortunate disadvantage of penetrating, to a considerable extent, the paper upon which it is employed.

With this colour we can dismiss the blues and pass on to the purple pigments. In this class we find the following pigments, viz., purple madder, purple lake, burnt carmine, Indian purple, violet carmine, and mauve. Taking them in the above order the first to claim our attention is—

Purple Madder.—As the name suggests, this pigment is a lake prepared from the madder plant, and is, I think, the only purple which may be considered durable. It is of a marone-purple hue, and possesses great transparency. It is remarkable much more on account of its subdued richness and beauty rather than for its brilliancy. To the water-colour painter it is a most useful colour, as by its use he

can secure the greatest depth of shadow and still avoid any unpleasant coldness of hue.

Purple madder, under all ordinary conditions of exposure to light, may be safely looked upon as practically permanent. It has been found that, even when exposed to direct sunlight, it resists its influences for a very long time, although in the long—very long—run it will no doubt fade. It may be looked upon as the most permanent of all the madders.

REDMOND BARRETT.

THE NEGATIVE IMAGE.

I.

THE possibility of improving the method of securing the photographic negative image must be a matter of permanent interest to all. Among the advances yet to be made in this direction, that of being able to take a picture that does not require development is, I consider, entitled to a front place. The isolation and facilities for commercial production of a sensitive body that will yield a visible negative impression with a short exposure in the camera, while causing the outside world far less concern than a measure of ascertained progress in orthochromatism, or photography in natural colours, would so thoroughly recast the economics of operative photography as to deserve being esteemed a revolution of the first magnitude. It is not improbable that before the second *desideratum* above-named has entered upon the period of gestation, the latent image will have become a reminiscence.

We are at present unable to obtain a perceptible darkening of the gelatinised silver haloids in the camera, except by carrying the exposure to great lengths. If we sink the qualification and only recognise the fact that the result specified is to be had as the inevitable effect of constant casuality, we may hold that the time required to produce this darkening is to be judged with the comparative exactitude by which we measure the duration of the exposure needed for the invisible developable impression; and experiment proves this to be the case.

But, although the precise relationship of the "prolonged" to the "normal" exposure is so distant as to render any detailed information upon the subject valueless, save as a curiosity, the darkening of silver bromide in the camera may be observed without difficulty. There are few who are not familiar with what is called solarisation: the appearance, upon development, of a positive instead of a negative. This unwelcome guest seemingly comes without rhyme or reason; but it is not to be doubted that its presence can be justified on scientific grounds, for it is producible at will by over-exposure. Further, by a sufficient prolongation of the exposure the phenomenon may be made to take the still more remarkable shape of a visible positive impression, appearing, when viewed by transmitted light, like the picture one might get by the development of a well-solarised plate. As a rough indication of the conditions under which the effect presents itself, the writer may mention that with the sun at its maximum power on a bright midsummer day, a lens of the rapid type, a film of the instantaneous description, and for subject a landscape, the normal exposure was multiplied a hundred and fifty times. Perhaps it should be remarked that these effects are of less interest from a pictorial than a philosophical point of view.

In regard to negative effects upon silver bromide in the camera, there is not the advantage of being able to speak with similar assurance. A note made very many months since records the observation of such a darkening upon a film of the slow series, the haloid of which was doubtless a compound. The results obtained were indecisive, and, unlike the positive effects above referred to, entirely vanished in the general reduction shortly after the plates were taken into white light for the purpose of being better scrutinised. The exposure given was seventy times the normal. A "successful" repetition of the experiments was not to be had, but, despite the failure, it is possible that results as marked as those of the inverse case above alluded to are to be obtained by a proper appreciation of the necessary conditions.

As it is only after light has acted for a lengthened time that the darkening in the camera is made manifest, so, in like manner, if a sensitive plate is held by the hand, either in bright or subdued light, a measurable period elapses before a change is observed to commence. The dark body so formed is, we must assume, chemically identical with that of the positive obtained in the camera; and no doubt the time that passes before the change is seen in the plate held in the light has a like relation to the exposure requisite for the mean darkening as that given to the plate exposed in the camera bears to the abnormal or prolonged exposure. In both instances, as indeed in all relatively similar cases, the time occupied to form the invisible

developable impression possibly stands in fixed proportion to the exposure that calls the visible darkening into play.

To go by analogy alone, there is every reason for looking upon the lower body formed by light of the bromide to be a definite chemical substance, having constant properties, composition, and reactions, and differing in several important respects from the original compound as distinctively as the iron proto-salts differ from the per-salts. Moreover, as the darkening obtained by prolonged exposure, the visible action of light upon the sensitive mixture, must originate largely in or upon invisible sub-salt, there arises the strong suggestion that in a separate state this substance would exhibit properties of considerable interest and value. Indeed, it may be found possible to isolate several combinations of silver and bromine.

The comparative facility with which the ordinary silver compounds are sensibly changed in the light has always, to the mind of the writer, seemed a finger-post to an era in photography when light, the great developer, would be allotted the functions now performed by auxiliary reagents. The results of certain experiments induced by the foregoing superficial data and reflections tend to strengthen a belief in the possibility of obtaining visible negative effects in the camera as easily as invisible results are at present had, a belief not now first expressed; and to these it is proposed to advert on another occasion.

THOMAS BEDDING.

PROCESS PRINTING.

It does not say very much for the boasted mechanical genius of this country that we are so far behind our compeers on the Continent, who turn out, it must be admitted, far better work in the various mechanical processes connected with photography than we have yet done, and whose general average of such work is also higher. True it is that few of our army of photographers, professional and amateur, have much knowledge of such work, but the same must have been the case on the other side of the water, where the perfection to which they have brought this class of work should put us to the blush. This is true of America as well as of Europe, as we have examples of the finest work which have their origin on the former continent. What can be the reason of it? Is it because of our system of extreme subdivision of labour, or what? I am induced to make these remarks from seeing and finding the extreme difficulty of getting such work well executed here.

It is not alone in photo-engraving, though that, one would think, should find its best exponents in the birthland of the art of mezzotint, and where by far the finest works in that style of art have been produced—witness the magnificent series of Sir Joshua Reynolds's portraits and others of his period, and those have been at least equalled by our cousins, Faeds and others of the present day. Can it be, as was remarked by an American cousin at the Paris Exhibition the other day, that we do not pay sufficiently well for the services of those who have made themselves masters of this kind of work? As he said, and he had been sent over specially on this mission, "We count no salary too high for the best talent, and don't consider ten, twelve, or fifteen pounds a-week dear for such service;" and he was speaking only on work for illustrated periodicals. We, he also said, have to send here, at present, for our best work.

So, again, with the processes on hardened gelatine, with Woodbury inventing and leading the way; with the exception of that one which bears his name, we cannot come up with printing inks to the results we see produced elsewhere. I, at least, have never yet seen one done here which would compare with a silver print from the same negative, but have seen such produced elsewhere so perfect that the most critical could find no objection to. Even the very inequalities of tone and finish which we sometimes suffer from in silver printing seem to be intensified in the mechanical print. This cannot be from want of skill, but only from want of application.

It may be as McGlashan, one of our best steel-plate printers, as well as a good photographer, once remarked, that the good workmen are too good; what we want is to raise a crop of woodenheads for this kind of work, men who would be trained to this exclusively. It would seem that it needs a continual series of editorial digs to get us out of the conservative groove into which most tradesmen are apt to fall, and remain there.

W. H. DAVIES.

EXPERIMENTS WITH BROMIDE PRINTS.

[A Communication to the Photographic Club.]

You will no doubt remember that at a meeting of our club the question of reducing bromide prints by treatment with old oxalate developer, followed by immersion in the fixing bath, was raised. The discussion originated from an experiment witnessed at the Eastman

Company's place, and several members stated that they had tried the process, some of them without success.

Mr. Bridge has kindly sent me some deeply printed bromide enlargements, with a request to investigate the subject.

I now beg to lay before you the results of the experiments which I have made, and at the same time to submit the prints which I have treated by the process under consideration.

The case in point may be stated as follows:—A finished bromide print is immersed in some old oxalate developer; it is then transferred to the ordinary fixing bath.

Does it suffer any reduction under this treatment?

I think it will be best to describe, first of all, the solutions used in the experiments.

Developer.—This had been long in stock and had been already used for developing several prints. It had been kept in a closely stoppered bottle, and was perfectly bright and clear. The colour was a bright yellow, and at the bottom of the bottle was a small quantity of the well known green crystals. Tested with litmus paper it was found to be very faintly acid.

Hyposulphite solution.—This was freshly made, and consisted of three ounces of the salt to one pint of water. A piece was cut out of one of the prints so as to embody both dark and light parts, and was then soaked for some time in clear water. It was then well drained and flooded with the developer for five minutes. After being drained again, it was transferred without washing to the fixing bath. So as to make the experiments under similar conditions, each print treated was left in the hyposulphite for fifteen minutes, this being, I believe, the average time allowed for the fixing of bromide prints. The dish was rocked from time to time.

A very perceptible reduction took place, as you can see by comparing the cut piece with the original print. There is also a modification in the colour of the print. The same process was repeated with another piece of the same print, the old developer being rendered acid by the addition of a few drops of acetic acid. As you can see, there is not much difference either in the amount of reduction or in the tone of the pieces treated by either process. Half of this portrait was flooded with the acid developer and fixed as above. Here, again, we have reduction, but there is also a very considerable amount of yellow stain. I did not attempt to remove the stain, as this might, even if successful, alter the tone of the print and make it less comparable with the others.

I next soaked a print in water, and blotted off the excess after the paper had become thoroughly limp. I painted over part of the picture with acid developer to see whether I could reduce it locally. I found some difficulty in getting the developer to take on the gelatine surface. The reduction is not very considerable, but is still perceptible. The action is not energetic, on account, probably, of the small amount of developer which the gelatine is capable of retaining. I have indicated the part of the picture acted upon by a line in pencil.

It seemed probable that a fixing bath which had been used for several prints might exert a reducing effect on pictures fixed subsequently. In order to test this I submitted part of a print for fifteen minutes to the action of the hyposulphite. Both fragments of the print were then washed together in the usual way, so that any alteration in tone which might be due to prolonged soaking should be put aside. You will notice a certain alteration in the part of the print treated by the contaminated hyposulphite. I then added one ounce of the old developer as above to the twenty of hyposulphite solution, and placed in the mixed bath a piece of a print; the reduction was rapid, and at the end of fifteen minutes the result is what you can see by comparing the tone of the reduced piece to the remainder of the picture.

As it is highly probable that the reducing effects observed are due to the presence of ferric salt in the old developer, I made a half per cent. solution of ferric chloride and immersed a piece of a print in it for five minutes. After placing it for fifteen minutes in the fixing bath the image had faded considerably, and there is no doubt that by repeating the process it could have been made to disappear almost completely. I have here two prints from the same negative, done on Anthony's bromide paper. The developer was compounded by mixing one part of iron with nine parts of oxalate solution, a trace of bromide being added. Fresh developer was used for each print, and both were washed in three acetic acid baths, and then in several changes of plain water. They were then fixed for about twenty minutes in a freshly made hyposulphite solution (three ounces to the pint). When finished they were very nearly identical in depth, and had the same amount of detail. After washing the prints thoroughly, one was partially dried and half immersed in the solution which had been used to develop it. After fifteen minutes of renewed fixing the immersed part had considerably faded. On examining the print you will notice how much

of the detail has disappeared, and also that in places the faded image is replaced by a yellow stain effecting the same shape as the detail which has been reduced.

From this result it would appear that the action is very powerful, as but little ferric salt would be formed in the developer after the production of one print. At all events, the necessity for careful washing after development becomes apparent, and I think I may add that the same ought to be done after clearing with acid.

A few years ago I published, in collaboration with Professor W. Spring, of Liège, a research on the acids of the thionic series.* We found that when dilute sulphuric acid is added to a solution of hypsulphite of sodium a certain amount of sulphuretted hydrogen is evolved at first, and trithionic acid is formed. If the addition of acid is continued, sulphurous anhydride comes off, as it is well known.

I mention this fact here, as there might be a possibility of either of the gases indicated having some influence on the print.

A. LEVY.

PHOTOGRAPHS OF THE RED END OF THE SPECTRUM.

IN November, 1875, I exhibited to the Society some photographs of the red end of the spectrum about A and a short distance below it, obtained on dry collodio-bromide of silver plates stained with aniline blue and given a momentary exposure to white light before being acted on by the spectrum. In these photographs, however, it was noticeable that under the influence of the red as well as of the blue rays the image of the spectrum was strongly reversed, i.e., instead of being a photographic negative it was a positive showing the lines as dark lines on a clear ground. The photographs now before you are on gelatine dry plates stained also with a blue dye, but they show no traces of this reversal in any part of the spectrum, and not only extend much further into the infra red region, but show infinitely better definition and greater dispersion in this part of the spectrum, owing to the employment of gratings in place of prisms.

The dye I have used for staining these plates is alizarine blue¹ (C₁₂H₇NO₂), the quinoline of alizarine. It is prepared from nitro-alizarine by heating it with glycerine and sulphuric acid, and is found in commerce as a paste insoluble in water, and only slightly so in alcohol. It dissolves in liquor ammonia with a greenish-blue colour. By mixing the paste with a concentrated solution of sodium bisulphite the dye dissolves, and when dried forms a dark purple powder, known as alizarine blue S, or anthracene blue. In this form it is readily soluble in water, the solution in distilled water being at first of a brownish orange colour, turning blue on exposure to air. By keeping a few days the colour forms a flocculent precipitate, and is then only partially soluble in dilute ammonia.

Examined with the stereoscope, solutions of the dye do not give a very marked absorption spectrum.

The plain orange solution of alizarine S in distilled water absorbs the violet, blue, and green up to about *b*.

The greenish-blue ammoniacal solution absorbs the red, orange, and yellow very strongly down to about D $\frac{1}{2}$ E, with a general lowering all over the spectrum. There are no distinct absorption bands. I do not find any marked difference in the absorption spectra of the ammoniacal watery solution of three samples of the dye in my possession.

I. Alizarine blue paste, from the Elberfeld factory, formerly F. Baeyer & Co.

II. Alizarine blue S, from the Badische Anilin and Soda-Fabrik.

III. Anthracene blue, from Dr. Schuchardt, of Görlitz.

In his work, *Practische Spectral Analyse Irdischer Stoffe*, Dr. H. W. Vogel gives two very different absorption spectra for the ammoniacal watery solutions of pure alizarine blue and of anthracene blue, also obtained from Schuchardt; the first agrees with my observations, but the second, which shows maximum absorption between D and E, does not.

The photographs now exhibited have, for the most part, been taken with No. II., but others have been taken with Nos. I. and III. The effect of all of them seems very similar, but further trials are required to ascertain which is best.

The plates that I used have been the ordinary commercial gelatine dry plates. Wratten's "Instantaneous" have perhaps given me the best results, but the "Ordinary" have also proved wonderfully sensitive under the action of the dye. The plates are stained by bathing them for one or two minutes in a solution of the dye in distilled water in

* "Recherches sur les Acides Tetra- et Trithioniques." W. Spring & A. Levy. "Bulletin de l'Académie Royale de Belgique," 2^e Série t. XLII., No. 7. Juillet 1875.

the proportion of one part of the dye to 10,000 parts of distilled water, with one per cent. of strong solution of ammonia added. The solution has at first a strong greenish tint, but this soon changes to blue, and I have noticed that after a time it again takes a greener tint.

With a small spectrograph on Dr. Vogel's principle, consisting of a Browning pocket spectroscope attached to a camera in front of a single element of a small Steinheil applanatic lens (the addition of this lens is, I find, a great improvement to the instrument as originally proposed by Dr. Vogel) the spectrum obtained on the stained plates shows very intense action through the violet and blue regions as far as *b*; from *E* to *C* there appears to be a minimum of action, and then it rises again with clearly marked bands of increased sensitiveness between *C* and *A*, strongest between *C* and *B* and *a* to *A*. Below *A* the sensitiveness quickly diminishes.

I have found the sensitiveness to red to differ considerably on plates prepared at different times, and have not yet discovered to what this is due. With a screen of deep ruby glass in front of the slit, the sensitiveness to red becomes very marked, and the maximum sensitiveness is found between *D* and *A*, the remainder of the spectrum being either cut off at *D*, or showing only slight traces of action from *F* to *H*, according to the length of exposure.

On a plate taken about 8.30 a.m. on the March 19, with the plane Rowland grating in the first order spectrum, using a deep ruby glass screen, exposing ten minutes, the slit being .02 millimetre, the sensitive action in the red commences just below *D*, and seems gradually to increase to *A*, then diminishing to about λ 8000, beyond which lines are distinctly visible beyond the *Z* group up to about λ 8400. Considering that these photographs have been taken without any special appliances for securing the transmission of the infra red rays, it is probable that with them a much greater extent of the infra red spectrum might be photographed on plates stained with this dye.

With the concave grating also, using a deep ruby glass screen, I have been able to obtain lines in the infra red region to about λ 8300 with much greater dispersion and distinctness than the plane grating will give. The photograph I have with me shows the spectrum from *C* to *A* and below. It is taken on a Wratten's "Ordinary" plate, a slow kind, which unstained would show no action beyond *E*. It is unfortunate that the sensitiveness of the plates falls off so much just below *A*, so that the infra red spectrum has not sufficient density to print well, although up to *A* the image shows too much density for the lines to print clearly. The various photographs, however, serve to show the value of the dye as a ready and simple means of photographing the spectrum from *C* to *A* with ordinary dry plates.

Using plates stained with a special preparation of quinoline blue (cyanine) and sulphate of quinine, Mr. J. C. Burbank has been able to photograph the infra red rays from *A* to λ 9900, or to about the limit of Captain Abney's latest map, which was prepared from photographs made on collodion plates containing a greenish form of bromide of silver specially sensitive to the infra red rays. I have tried cyanine prepared in this manner, and found, that though it is undoubtedly sensitive to the infra red rays, its maximum sensitiveness is between *D* and *B*, and between *B* and *A* its action is much weaker than that of alizarine blue.

The cyanine and quinine solution, however, is troublesome to prepare, and neither it nor the plates keep well; moreover, the dye is expensive, so that some more simple and more certain stain is desirable, and if alizarine blue, which chemically is allied to cyanine, can take its place for such observations it will be an advantage. I may mention that it has already been tried by Schiendl and Eder, but they do not appear to have recognised its great sensitiveness for the red rays, which is not so apparent with prism spectroscopes as with gratings, and requires the use of yellow or red screens to produce its full effect.

Dr. Eder has recommended corulein as a sensitiser for the red rays; but though it certainly is useful the maximum of effect is produced between *B* and *D*, while with alizarine blue it is between *C* and *A*. I have also found it uncertain in its action, but hope to make further trials of it with the gratings, as well as of a dye called galloxyaniline, obtained by the action of nitroso-dimethyl-aniline on tannic acid, which, also, I have found, is a strong sensitiser for the red rays.

I have also lately been trying a new fluorescent phthalein dye, recently introduced by the Badische Anilin and Soda Fabrik, called rhodamine (the phthalein of meta-amido phenol), which I thought might be likely to be useful in orthochromatic photography for copying coloured drawings, &c. It undoubtedly has capabilities in this direction, but, so far as I have tried it, seems inferior to erythrosine in sensitiveness for yellow. It is prepared by fusing phthalic anhydride with diethyl-meta-amido-phenol, and forms a reddish violet powder, very easily soluble in water, the solution being of a bright crimson with a strong orange fluorescence. It is not very soluble in alcohol. Acetic acid dissolves it, and the solution shows a very vivid scarlet

fluorescence. Ammonia produces no visible change. Dilute mineral acids slightly redden, but do not, as with the eosines, destroy the fluorescence of its watery solutions; on the contrary, they rather heighten it. Nitrate of silver precipitates it from the watery solution, but not readily; the brick-red precipitate is very soluble in pure water.

Examined in the spectroscope a strong watery solution absorbs the spectrum strongly in the blue, green, and yellow from *a* $\frac{1}{2}$ *D* to *F* $\frac{1}{2}$ *G*, though the only distinct absorption band with a weak solution is about midway between *D* and *E*.

Gelatine dry plates stained with a solution of rhodamine in distilled water at 1:10,000 with one per cent. of solution of ammonia, show two very marked regions of increased action—one between *G* and *F*, the other from *E* to *D*, strongest from *D* to *D* $\frac{1}{2}$ *E*. The photographs taken with the small spectrograph show a curious, but well-marked series of bands of increased sensitiveness in the parts of the spectrum where the action of the dye is most marked. The action of the yellow rays about *D* is quite as strong as, if not stronger, than on plates stained with the best of the eosine dyes, but for copying coloured pictures I have not found rhodamine with ammonia equal to erythrosine either with or without the yellow screen; further trial is, however, requisite.

The addition of a small quantity of nitrate of silver to the ammoniacal solution of rhodamine greatly increases the general sensitiveness of the plates, but does not seem to heighten the yellow sensitiveness, either with the spectrum or with coloured pictures, so much as it does with erythrosine.

It is, however, noticeable that plates stained with a solution of the dye containing acetic acid in place of ammonia appear almost as sensitive in the yellow as those prepared with ammonia, and give about equally good results for copying work. If, on further experience, this is proved and found to work with certainty, it will be of importance, because the use of eosine dyes in conjunction with ammonia for staining gelatine dry plates for orthochromatic photography has been protected by various patents. It is possible that further experiments with acid-stained plates in conjunction with the use of specially suitable yellow screens might result in a method of using this dye for orthochromatic photography which would be efficient and open to general use.

In photographing the spectrum with the concave gratings I have found the rhodamine-stained plates useful for the region immediately about *D*. On a plate I have with me, showing the *D* lines in a second order, seven lines can be clearly seen between *D*₁ and *D*₂, though eleven are sometimes visible to the eye.

Another new dye from the same manufactory, called *Nile blue*, which also belongs to the rhodamine series, shows considerable sensitiveness to the region between *D* and *B*, by the addition of ammonia; though not so much as alizarine blue. Without ammonia the general sensitiveness of the plate is much reduced, as Dr. Eder has remarked is the case of most blue dyes, and the image of the spectrum does not extend beyond *b*.

It is noticeable that the spectrum taken in the small spectrograph on plates stained with the ammoniacal solution of this dye shows numerous narrow bands of extra sensitiveness similar to those in the spectrum of rhodamine, showing that both dyes belong to the same group. These bands in the photographed spectra of the two dyes would be an interesting subject for further inquiry.

I have to acknowledge the kindness with which the managers of the Badische Anilin and Soda Fabrik have supplied me with samples of the dyes referred to.

J. WATERHOUSE, Colonel.

—Trans. Asiatic Society.

MONOPOLY AND PHOTOGRAPHIC TRUSTS.

MONOPOLY is a word of unpleasant sound to American ears. It is in direct conflict with our free-born ideas of equal privilege. Kings were used to reward their favourites with exclusive control in certain lines of business, with power to decide prices, limit the supply, and govern the distribution of the product, thereby extorting an exorbitant revenue from consumers. This monopolistic extortion was considered by the people in the nature of highway robbery on land, or piracy on the seas—being criminal injustice when inflicted and manhood degradation when submitted to. It being so well understood that the word monopoly has an aggravating sound to the ears of all freemen, the monopolistic robbers in the fair domain of honourable business nowadays evade the unpleasant sound by calling their combinations "Trusts." Yet as a rose by any other name is just as sweet, so monopoly by any other name is just as bitter to those who suffer from its extortions. And as the evil of our Southern slavery—which was the greatest monopoly of labour the world ever saw—was not

confined only to the slave who was degraded by submission, but injured also the owner, who, fed by the pride of unrestrained power, was made arrogant and haughty by his own tyranny, so the injury of trusts is not only to the people who suffer under their exactions, but successful monopoly naturally becomes arrogant and domineering in a way that, if carried to its logical results, must draw upon itself the same evil consequences that were brought by the tyranny of slavery, which grew more and more insolent in its exactions, until, in righteous retribution, its crimes were washed out in its own blood.

Knowing the inexorable laws of evil growth from unrestrained permission in the exercise of unjust power, it must be alarming to all who love liberty and equity to see the rapid growth of monopoly under the guise of trusts in our country, and excite many fears for the time, sure to come, when a fierce struggle between the forces of insolent monopoly and freemen battling for their rights will again desolate our land.

These strictures do not mean, however, that the writer is opposed to all associations for improvement of prices and the elevation of photography. He believes that association is not only useful but necessary, but association based on nobler principles and more humane methods than have actuated the trusts which are now sucking the life-blood of the country.

The rough labourer, when he finds a competitor who is able to do more work for less pay, and yet give better satisfaction, gets angry, and falls upon him and beats him, and drives him away or kills him. That is the power of muscle.

A. T. Stewart—a good representative of the monopolistic class—if a young man started in his line of business near him, would sell goods in that line at cost, or less, until the competitor was ruined or driven out. That was the power of money with unscrupulous greed.

Another class, with old-fashioned ideas of honesty, would endeavour to give better goods, use greater efforts to please, manage business with more energy and economy, and abide the result—often, indeed, lending a helping hand to a young competitor less capable, but bravely struggling, setting him in the right road, and bidding him God-speed instead of combining to crush him. Success in that kind of competition comes from the power of character and skill, and is the only kind that an honourable man in any business can take pride in attaining.

Let us hope, then, that the term "Photographic Trust" will never become familiar to our ears in connexion with such unscrupulous and infamous methods for crushing out opposition as have characterized the monopolising trusts that now threaten the peace and endanger the liberties of our country. E. K. HOGAN.

—Con. Number St. Louis Photographer.

NOTES FROM NEWCASTLE.

THE lantern demonstration, held under the auspices of the Newcastle Photographic Association, was a very successful affair. I heard of dozens, at least, being unable to get into the lecture hall, amongst them being several members. The only complaint I heard was at the short time allowed for each view or projection. The judges were Messrs. Allison, Spence, and Laws. It may not be out of place to mention here that the Society was fortunate in getting the services of three such men. Mr. Allison is an amateur and an expert in optical and lantern matters, and one of the best judges of what a lantern slide should be technically. Visitors to the Newcastle Royal Jubilee Exhibition will remember a splendid working model of the triple expansion engines built for the Royal Italian cruiser, *Sardagna*, by Messrs. Hawthorn, Leslie, & Co.; this was the work of Mr. Allison. Mr. C. J. Spence is also an amateur, and an artist of no mean skill; while Mr. P. M. Laws has officiated more than once previously.

I congratulate Newcastle's only medallist (this year's Photographic Society's Exhibition), I mean Mr. Lydell Sawyer. I had the pleasure of viewing privately most of these pictures, and consequently was fully prepared for the verdict of the judges. I should not be surprised to find in Mr. Sawyer a second "Robinson." In some notes of mine recently, I hinted that to view Mr. Sawyer's best work one should go inside. Strange to say, I had the same feeling with regard to his *Studies*, and I doubt very much whether Mr. Sawyer has not in existence a still superior work to any on the walls of the Pall Mall rooms. However, it is not for me to say anything further here—or elsewhere.

Mr. R. W. Weekes, late Hon. Secretary of Y.M.C.A. Photographic Club, leaves Newcastle shortly, having obtained a Whitworth Scholarship, and proceeds to London to pursue his studies at headquarters. Mr. Weekes is an electrical engineer. The Y.M.C.A. organ says of him:—"In his work with us, Mr. Weekes was all but ubiquitous. He was an active member of the bicycle club, tennis club, photographic club, a member of the general committee, a visitor, a steward, a committeeman of the Sunday afternoon Bible Class, the most active secretary of the open-air work, and a most indefatigable worker in connexion with our Sunday evening evangelistic services. Long though this list is, we believe that it does not

cover all Mr. Weekes's Y.M.C.A. work. And yet he found time to study so effectively as to gain a valuable scholarship."

The local Society's Council has made a move in the right direction by lowering the subscription to 5s. per annum, but something more must be done to make the Society in any way worthy of this large industrial centre. The same rules which may guide the members of the "Eatonswill Photographic Society" are out of place here. What Cardiff, Dundee, Derby, Nottingham, and Oldham are doing (amongst others) should be done in Newcastle, and not a year should be allowed to pass away without its "Exhibition of Photographs." This is, in my mind, of the most importance. At present, if we do not journey to London during the month of October, or thereabouts, we have no chance whatever of seeing the works of the leading photographers; and how much is learned by viewing the works of others is well known. The Newcastle Society wants less parsimony and more ambition.

D. D.

A CORNER OF CHESHIRE.

ON the borders of the palatine county of Cheshire, where it is divided from the neighbouring county of Stafford by the lofty ridge of Mow Cop, and at the foot of that eminence, stands one of the most interesting old houses in the kingdom—certainly one of the most genuine and complete relics we have left of the domestic architecture of mediæval times. Come with us, this late August day, on our photographic visit, and let us enjoy together a place we have long dreamt of and wished to see. The North Staffordshire Railway does not boast of much mileage, but it runs through a lovely district—always barring the potteries—and past many a place of note, famed for its comparatively modern attractions, such as Alton Towers and Trentham, or for their more ancient and still greater interest and picturesqueness, in such places as Gawsworth and Little Moreton, or Old Moreton Hall, as it is more commonly called. To the last-named, then, if your tastes lie in the same direction as our own, let us wander and dream away the happy, sunny day—we say dream, though we mean to do a good day's work, for do not such places stir up the imagination, carry one back to far distant times, and set one a-dreaming?

We leave the train at Mow Cop Station, and a walk of a mile and a half over pleasant fields brings us to our destination. On our way we have had peeps of the old hall through the trees to heighten the sense of coming enjoyment. But here we are; after passing the end of an ancient barn and through the gate, Old Moreton Hall stands revealed in all its antique beauty—a vision of the times of old. We stand admiring and spell-bound—it is like some scene of enchantment, "some fairy palace of the days of old romance." For colour and broken outline it cannot surely be equalled. Look at the lofty gable with its ornamental oak and plaster work and its great windows overhanging the entrance gateway, the dark gateway so rich in carving; look at the flat-arched Gothic bridge spanning the sullen waters of the moat, the only approach or entrance; look at the numberless gables with their carved pendants, the great ivy-covered chimney, and the whispering willow beyond the bridge—you never saw anything finer! We draw near the bridge and look through the gateway into the courtyard beyond—it is like a peep into fairyland; we enter the quadrangle, and find ourselves surrounded by fresh beauties; nothing could exceed the wonderful effect of the north side of this courtyard, where the architect seems to have lavished all his powers to produce a miracle of lightness and strength, of use and beauty.

The first impression we get is that the building is nearly all windows, so many and so large are they; where there is no glass there is dark oak richly moulded or formed into quatrefoils and other devices, and filled in with creamy-coloured plaster. Two of the bays, of two storeys in height, are each formed of five sides of a decagon, differing in size, and surmounted by gables. The upper windows overhang the lower, and the lead work forms divers geometrical patterns. The doorway leading into the banqueting hall is, perhaps, the most elaborate piece of workmanship in the building—a mass of exquisite carving. All this great pile is of oak and plaster, none of it later than the time of Elizabeth. There are no restorations, so-called, to annoy the artistic eye, but all is toned down and mellowed with age, and the mind would have little difficulty in peopling the place with its former occupants. "Oh, for the revelation of fair forms, of the scenes of successful or sorrowful love, of the brideals and the burials, of the poetic dreams and pious aspirations, that have warmed or saddened these old halls through the flight of ages!" And yet dilapidation is there, soon to be followed by decay if some loving hand does not see to it, for in our rambles about the old rooms we noticed that some of the beautiful lattices were broken away, leaving the wind and rain free ingress.

Before we commence work let us look inside at these quaint, old rooms, first ascending the rude staircase on the south leading to the ball room, as it is called. This room is of great length in proportion to its width, being seventy-one feet by twelve feet; the open timber-work roof, rising to seventeen feet, is very elegant, and is ornamented with oak and plaster quatrefoils. Oak timbers have been placed across to act as tie-beams at some more recent date to prevent the thrust from pushing out the sides, which are considerably out of the perpendicular. The builder must have had a passion for light, for one end and the whole length of each side of the room is a continuous line of windows, the lead

work and small panes of which show a wonderful variety of intricate patterns. These long lines of windows are interrupted only by the door by which we enter on the north side, and by the room adjoining on the south side, which projects over the entrance gateway. This room, like the long gallery, is panelled with good old English oak, and has a highly ornamented fireplace bearing the heraldic shield of the Moretons quartering those of Macclesfield, and surmounted by the Moreton crest. On either side are large figures of Justice and Mercy. Descending, we now cross the courtyard, and entering by the porch—so suggestive of Prout—find ourselves in the banqueting hall, a spacious apartment, showing signs of present occupation, though, with the exception of the massive oak table running down the centre, the furniture and other accessories are inharmonious and out of place.

A spiral staircase, with steps of solid oak, ascends in one angle; at the opposite one, passing the foot of the principal staircase, we enter the parlour, oak-panelled, as all the principal rooms are, and with a deeply panelled oak ceiling. This room is lighted by one of the great bay windows we noticed in the courtyard on our first entrance; the other belongs to the banqueting hall.

We have no time to note all we see, and we come out into the courtyard again with a mixed recollection of coats-of-arms, quaint carvings, antique panelling, and deeply recessed windows of great beauty, wherein the sunshine comes lovingly, as it did centuries ago, glorifying the heraldic blazonries, and casting their rich hues on the bare floors. Crossing to the opposite angle of the courtyard we come to a small doorway leading into the chapel—a sad scene of desolation, dirt, and damp; this is the gloomiest part of the building we have yet seen. There are a number of texts in old character on the plaster of the chancel, but we will not stay to attempt to decipher them. The east window is of five lights and pointed, and the size of the chapel proper is about twelve feet by nine, though the entire structure is thirty feet long.

We shall not enter any more of the doorways on this eastern side, for they lead to nothing particularly interesting, and we must beware of the mastiff here who strains at his chain, and barks in a very ferocious and menacing manner whenever he sees us in the courtyard. Besides the banqueting hall and another room or two on the ground floor on the north side, the farmer tenants occupy a part of the south side as kitchens, &c. We are not invited to see the bedrooms, with those glorious overhanging and curious windows, which we read "are rendered additionally interesting by the names and inscriptions traced upon the panes by former occupants and guests. On one of them is written 'Jonath'n Woodnoth's' and 'Marie Woodnoth's,' with the date 1627, and beneath is the following couplet:—

'Man can noe more know weomen's mind by kaire,
Than by her shadow hede ye what clothes shee weare.'

Jonathan Woodnoth was the heir of Shavington, and married Mary, elder daughter of William Moreton, of Moreton, but what made him so spiteful against womankind is a mystery that is likely to remain for ever unsolved."

Now, we will go outside again, over the bridge, and commence exposing our plates, having regard to the shifting shadows, in the intervals exploring the moat and the garden, and noting when such-and-such views may be best taken. We make our mid-day meal from our wallets while we photograph in the long gallery and the adjoining room. We also make a few notes of the curious emblematical figures with their quaint mottoes at either end of the gallery, and don't omit to copy the following inscriptions carved in bold relief on one of the beautiful windows in the quadrangle below:—

GOD IS AL IN AL THING
THIS WINDOWS WHEIRE
MADE BY WILLIAM MORETON
IN THE YEARE OF OURE LORD MDLIX
RYCHARDE DALE CARPENTER MADE
THIS WINDOWS BY THE GRAC OF GOD.

Well done, Rycharde Dale! Thy hand and thy brains found something to do, and thou didst it with all thy might! The lovely doorway adjoining is doubtless also the work of thy skillful hand, from the dragons in the spandrels and the exquisite zigzag ornamentation to the spiral pillars forming the doorposts; a clever "carpenter" truly wert thou, and time has dealt lovingly with thy name and work by adding a new grace and beauty in the rich colouring he has spread over this creation of thine. Thy earnestness and devoutness are here truly testified, and who can doubt that thou wert a sincere follower of One Who was Himself the son of a carpenter. We feel grateful to this man who wrought so successfully three and a half centuries ago, and to his patron, William Moreton, for the great treat we have had, and for the charming pictures we hope to have when our plates are developed. Thanks to platinotype, this thing of beauty may now become a joy for ever.

A short history and description of the place and we have done. In the Domesday Book we find mention of the Ville of Rode, then divided into

* The above quotation is from Croston's recent work, and it is given with some variations in an account of Old Moreton Hall, by E. Walford, written in 1865. Croston also mentions other inscriptions. These have all disappeared however, for since writing this article I have paid a second visit to Little Moreton on September 12. I got admission to the bedrooms, and on inquiring of the present tenant of the house where I could find these inscriptions, was told that she had never seen them, though she had lived there twenty years.

the two manors of Moreton and Rode. The Conqueror granted the Earldom of Chester to Hugh Lupus, and he distributed the lands amongst his followers. The manor of Moreton was held by knight service, and gave its name to the family who possessed it. From the time of Henry III. the estate continued in strict male descent until the time of Sir William Moreton, Knight, Recorder of London, who died childless in 1763. One of the Moreton's married the daughter of Sir Andrew Brereton, by whom he had, with other issue, a son, William, born a year or two after the accession of Henry VIII. He probably began the erection of this manor house on the site of an earlier building, his son, John Moreton, who died about the end of Elizabeth's reign, completing it.

This old manor house with its garden occupies about an acre of ground, and is entirely surrounded by a moat. It stands close by the road leading from Congleton to Newcastle, on a sandy plain in the south-east corner of Cheshire, and is about four miles distant from the former town. The buildings on the south or principal front are lofty, and the long gallery or ball room, running along the whole length, is much narrower than the storey below it. The ancient bridge and entrance gateway are in the centre of this frontage; an old stone horse block stands within the gateway, where also are doors communicating with small rooms, one of them, probably, the porter's lodge. The best general views are from the south-east and south-west. Outside the moat, at its south-west corner, is an artificial mound of uncertain origin and use, which affords a good standpoint, and embraces more than any other view; a similar mound of smaller size is at the north-west corner within the moat. We have already attempted to describe the courtyard with its surrounding buildings; none remain on the west side; the east side, saving the chapel, we did not explore.

We are indebted to our friend, James Croston, F.S.A., for some particulars in our short account of this jolly old house; and those who would know more about it will find an exhaustive and excellent historical description in his interesting work entitled *Historic Sites of Lancashire and Cheshire*.

Our fourteen plates are all exposed and our traps packed up and we start off on our return journey by Astbury, casting many a lingering look behind. The sun shines brightly on the chequered walls of the old pile as we look our last farewell; a field of corn in sheaves makes a good foreground, while the eminence of Mow Cop forms a fine distance to the scene. But, alas! all our plates are spent. We have time to look over the church at Astbury—where so many of the Moretons lie at rest—a good example of the later Gothic period, the clerestory windows being of unusual size. We shall not tarry here, but get a glass of stout at the neighbouring inn and then finish our walk to Congleton, admiring as we go the distant hills which stand out boldly in the light of the westerling sun.

The Convention of 1890 is to be held at Chester. The country is full of old halls and manor houses, and we look forward to a rich treat, feeling at the same time that no place can surpass in interest to the artist or photographer the ancient moated manor house of the Moretons.

RICHARD KEENE.

THE VESEY CLUB AND THE BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE visits last week of the Birmingham Photographic Society to the Vesey Club, and the reading of technical papers on the various processes of photography by Mr. W. S. Horton, Mr. W. J. Harrison, F.G.S., Mr. E. H. Jaques, and Mr. E. C. Middleton, having resulted in an important step being taken towards carrying out a valuable project, which has for some time been under the consideration of the Birmingham Society, namely, to preserve by means of photographs current records of everything throughout the county of Warwick of archaeological, ethnological, and scientific interest. The Vesey Club have consented to appoint a committee to act with the Society in carrying out the proposal. It is intended that the county should be mapped out into areas, and amateur photographers throughout the county invited to take individually a small portion of country, and secure views of every object of interest within that area. The Vesey Club will issue a circular asking proprietors, authorities, and all interested, to render assistance, and arrangements will be made for copies of the whole or part of the series of views to be afterwards on sale. It is, of course, contemplated taking the views in uniform size, and having them reproduced by processes of a permanent character. At least two complete series will be set aside for permanent preservation and public reference, one to be deposited at the British Museum and another in Birmingham. Other sets will probably be retained by the Birmingham Photographic Society and the Vesey Club.

Mr. W. J. Harrison, Vice-President, and Mr. J. H. Pickard, Hon. Secretary of the Birmingham Society, are taking the greatest interest in the subject, and Mr. J. B. Stone, on behalf of the Vesey Club, has offered to render every possible assistance in carrying it out.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday next, October 22, at eight p.m., at the Gallery, 5A, Pall Mall East, when the apparatus now on view at the Exhibition will be explained.

Foreign Notes and News.

HERR ALPERS points out in a recent number of the *Photographische Correspondenz*, that gelatine plates require a much longer exposure when employed for photographing interiors than do wet collodion plates. He recently photographed an interior by means of the latter process, exposing for three hours, and afterwards desired to reproduce this same interior by means of a gelatine plate, at least ten or fifteen times more sensitive than the former. He expected that an exposure of half an hour would suffice. On developing, however, it appeared that scarcely any result had been obtained. He finally found it necessary to expose for five hours. The author explains this as follows:—"Bromide of silver," he says, "is much more sensitive to strong rays of light than is the iodide, but is not more sensitive towards feeble rays than is the latter. This also explains why the negatives of gelatine portraits are generally harder than collodion negatives." In reproducing interiors with windows situated in front of the objective, Herr Alpers finds it a very good method to cover them with red tissue paper, which he removes a few seconds before the exposure is ended.

HERR VOOZL, jun., says, in the *Photographische Mittheilungen*, that the complaints made of hydroquinone and pyro developers often turning brown are traceable to the employment of impure sodium sulphite. He has found that the best sodium sulphite deteriorates in about three days when exposed to the air, oxidising and losing its rates of crystallisation. When the sulphite is pure it is a crystalline powder, and will produce double the effect of that ordinarily supplied.

THE last general meeting of the "Friends of Photography in Berlin" was necessarily rendered a rather melancholy reunion owing to the recent death of Dr. Robert von Helmholtz. As was feelingly pointed out by the President, Dr. Vogel, in the course of his address, the deceased Professor was not only widely admired for his eminent scientific attainments, and loved for his amiable disposition, but was especially appreciated by the members of that Society, which he had assisted in founding and which he had always energetically supported.

PATENTS COMPLETED.

AN IMPROVED APPLIANCE FOR VIGNETTING PHOTOGRAPHS.

No. 15,376.—ARTHUR HAMMOND GOODALL, Rydal Cottage, Elms-road, Dulwich.—September 7, 1889.

In the method hitherto used for producing vignettes, an aperture is first cut of a suitable size and shape in a piece of card or other opaque material, and the edge of the aperture is then serrated (i.e., notched like a saw) with a pair of scissors.

My invention consists of an instrument somewhat the shape of a pair of railway ticket clippers, by means of which the said serrating or notching is accomplished in a more convenient and satisfactory manner.

The instrument as above stated is made on the principle of clippers, such as are used by railway companies to clip railway tickets (i.e., in an upper-cutting jaw worked by a handle, fitting into a lower jaw also worked by a handle, which said lower jaw has a piece stamped out the size and shape corresponding to the upper-cutting jaw.

In my invention I prefer to use only one cutting jaw as specified, though two or more might be used, and be altered in shape and graduated. In my invention the piece cut out from the lower jaw is V-shaped, and when using the instrument the length of serrates or notches can be varied at will from one-sixteenth to three-quarters of an inch in length as specified. When not in use the jaws of the instrument are kept apart by a spring between the handles as specified.

The use of the said spring is controlled by a stop as specified. The handles are curved upwards to give room for the knuckles, and so prevent the substance forming the vignetting shape being torn or creased.

The advantages of my invention are:—1. The time taken to produce a vignetting shape is reduced considerably less than a quarter as compared with the present method. 2. The angle of serrates or notches formed by the instrument in the vignetting shape being regular, a practically perfect gradation is produced in the print. 3. Any size vignette can be cut rapidly with equal perfection. 4. The original shape of the aperture of the vignetting shape is preserved. 5. Long and short serrates, or notches, can be cut regularly. 6. The handles being bent, additional serrating if required can be done without removing vignetting shape from printing frame. 7. In case any part of a negative is especially dense, one long cut or more can be made regularly or not as required. 8. Two or more vignettes can be cut at the same time. 9. Never requires sharpening.

IMPROVEMENTS IN PROJECTING LANTERNS.

No. 12,913. HERBERT CHARLES NEWTON, 3, Fleet-street, London.—September 21, 1889.

THE object of the present invention is to facilitate the projection on to any ordinary screen of objects which, from their nature, must lie in a horizontal position, and are incapable of occupying the ordinary position occupied by slides in projecting lanterns.

Hitherto the projection of horizontally placed objects has been effected in the following manner:—

The beam of light from the lantern is received upon a mirror placed at an angle, so as to reflect the beam vertically. A simple horizontal lens receives this beam, and converges it through the object, also placed horizontally, in an upward direction on to the focussing lens situated above it. The image is then received upon a second mirror, and thereby reflected on to the screen.

This arrangement has the disadvantage of being tedious and difficult when it is desired to show a horizontally placed object amongst a number of objects which need not be placed horizontally, and is also objectionable on account of the loss of light which the multiplicity of the mirrors and the situation of the lenses involves.

With the view of obviating these objections, I propose to employ a pair of ordinary dissolving view lanterns mounted one over the other, but the upper one I hinge to the lower at its back part, so as to make it capable of tipping backwards, and projecting an image in an upward, instead of a horizontal direction. A single mirror is employed to receive the image, and reflect it on to the ordinary screen.

The claim is:—A projecting lantern hinged to its base in the manner described, so as to be capable of projecting an image either horizontally or vertically at will, and the combination therewith of a single mirror, or its equivalent, for reflecting an upwardly projected image horizontally on to a screen.

IMPROVEMENTS IN AND IN THE MANUFACTURE OF PHOTOGRAPHIC PRINTING FRAMES.

No. 15,901. CHARLES TOMLINSON, Soho Iron Works, Oldham Road, Rochdale.—September 21, 1889.

My invention relates to the photographic appliances well known under the designation of printing frames, and has for its object to improve the construction of such frames, and, at the same time, to facilitate their manufacture. An ordinary printing frame consists, in so far as the frame proper is concerned, of two wood side pieces connected together by two shorter and thinner pieces, which I will term end pieces. The side pieces are rebated upon the edges which face each other when the frame is put together, the end pieces being equal in thickness to the ribs produced upon the side pieces by the rebating. The four pieces are usually or sometimes fitted together so as to form a slot and tenon joint, and the front inner edges of the frame are subsequently bevelled. In some cases the pieces have been bevelled before the frame has been put together. According to my invention I cut the side pieces from strips which have been bevelled and rebated, and the end pieces from strips which have been bevelled. I subject the side pieces to the action of cutters which simultaneously remove portions from each end so as to form a rebate equal to the thickness of an end piece, the inner face of each rebate being shaped to fit the bevelled edge of an end piece. The distance apart of the cutter spindles determines the length of the aperture in the frame. When the frame is glued together the bevelled edges make a mitre connexion at each corner. The corner joints are further secured by means of nails, pins, screws, or rivets. The end pieces are not so much weakened as in the ordinary construction hereinbefore described, and the cost of production is lessened.

PHOTOGRAPHIC CLUB.—October 23.—Subject, *The Ideal Camera*. Nominations for officers for the ensuing year and notices of alterations in the rules: must be given in at this meeting.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 10.—Mr. J. Hay Taylor in the chair.

A camera and stand, sent by Mr. Ramsden, of Leeds, was shown to the members. The camera was much admired for its lightness and the closeness with which it could be packed. The double dark slide was so constructed that the plates could be inserted and removed, without the turning of any buttons, by pressing under a spring catch at one end and letting them take into another catch at the other end. The handling of the plates was effected by leaving spaces in the frame at the centres of the long sides for the fingers to enter and lay hold of the edges of the plate.

Mr. W. E. DEBENHAM thought this plan open to the objection that light from the lens would strike upon the inside of the back of the slide and some of it be reflected up a little way on to the plate on being exposed, and so cause fogging. With some subjects, such as a dark interior, where a long exposure would have to be given, there might, at the open part of the frame, be the image of the sky through a window, and some fogging on the back plate through long-continued action of reflected light might be expected.

Mr. A. HADDON recognised this liability, but suggested that it might be prevented by having the black paper which was used to separate the plates cut with projecting semi-circles to fit the open spaces in the frame.

Other members thought that if the difficulty were one which would arise in use, the maker, as a practical photographer, would have provided against it.

Mr. L. MEDLAND showed a die for cutting the papers used as masks for lantern slides. The die represented half the circumference of the mask, and the paper was, therefore, folded previous to cutting. At first a wood block was used to cut upon, but lead was found to be much better.

Mr. J. TRAILL TAYLOR said that at an establishment where zinc etching of the higher class was produced a valuable block was recently found to be destroyed in a way which appeared inexplicable until it was discovered that a domestic animal had had access to the place in which the block had been stored.

A flexible tube for gas made on a new principle, of brass, and exceedingly strong, was exhibited by Mr. Callow.

This being one of the winter season "lantern nights," slides were shown on the screen by Messrs. Medland, Atkins, Hooper, Hastings, and Freshwater. Those by Mr. Hastings had been developed with eikonogen, and their tone and brightness met with due appreciation, especially a sea scene at Brighton, the negative of which had also been developed with eikonogen.

CAMERA CLUB.

THE first "Thursday evening" meeting of the session for technical discussion was held on the 10th instant, when Mr. W. ASBURY GREENE read a paper on *Detective Cameras*. Major J. F. Nott occupied the chair.

The chief part of Mr. Greene's address was directed to deprecating the offensive use of the hand camera for detective purposes by photographers. He referred to cases in which photographs had been taken under circumstances which must plainly and rightly have given offence to the person photographed. There was a very great danger here to the amateur's good name, and he thought the Camera Club should be to the fore in expressing an opinion on the point. Groups and individuals must be taken without the knowledge of those photographed, but it was a matter for the exercise of each worker's good feeling, and one in which some chivalry should be enforced by every means in our power.

The meeting showed enthusiastic and unanimous agreement on this point. Some discussion ensued, and was taken part in by Mr. Shipton, who described his stereoscopic hand camera, and by Messrs. Stroh, Shew, Samuels, Crouch, Fitzpayne, Davison, Beck, Cembrano, England, C. Wollaston, Ferrero, and others.

A large number of hand cameras were shown and explained, including Messrs. Shew's camera with roller slide, by the lecturer; the Key camera, by the Platinotype Company; Mr. Crouch's hand camera; the Facile, by Mr. Hindley (Mr. Fallowfield); three cameras of Messrs. Marion and Co.'s, namely, the Krugener and the Parcel camera in two forms, explained by Mr. D. P. Rodgers; Mr. Samuels's cameras; Mr. Beck's long-focus hand camera; roller slide and other cameras, by Messrs. Robinson, of Regent-street and Dublin; one constructed by Mr. Rushton; Messrs. Watson's camera; that introduced by Mr. Abrahams; and the new camera invented by Messrs. Swinden & Earps, two amateurs in Liverpool, which has recently received the Pall Mall medal award. Another camera was described by the Hon. Secretary, being one in which fifty plates somewhat under quarter-plate size were stored and worked. Great interest was taken in the very complete collection of apparatus. The ingenuity shown and the study and work given in the matter of hand cameras speak well for the vitality of this branch of photography.

A vote of thanks to the lecturer concluded the evening.

On Thursday, October 24, there will be the monthly lantern exhibition at the Club, when slides by Mr. T. M. Brownrigg and others will be shown. Meeting at eight p.m.

WEST LONDON PHOTOGRAPHIC SOCIETY.

OCTOBER 11.—Mr. W. England (President) in the chair.

After the reading of the annual report the CHAIRMAN alluded in feeling terms to the retirement, owing to continued ill-health, of the co-Secretary, Mr.

March. Bearing in mind that it was the first year of its existence, the Society was in a prosperous condition, both in regard to finance and numerical strength. He further announced that an exhibition would be held on January 10, and hoped the members would unite in endeavouring to make it a success.

The rules were then discussed and amended.

It was agreed that in future the annual subscription should be 10s., with an entrance fee of 5s.; lady members to be charged half fees.

The ballot for the election of officers was then proceeded with. The following gentlemen were elected:—*President*: Mr. Charles Bilton, B.A.—*Vice-Presidents*: Messrs. G. F. Blackmore, E. W. Foxlee, Dr. F. H. Low, and Walter Colls.—*Council*: Messrs. Charles Winter, W. Rickford, T. S. Hazeon, J. Hyatt, H. Power, T. B. March, C. Garner Richardson, Charles Whiting, G. E. Varden, and J. D. England.—*Auditors*: Messrs. Henry Selby and Leslie Selby.—*Hon. Treasurer*: Mr. Lionel C. Bennett.—*Hon. Secretary*: Mr. John A. Hodges.

Votes of thanks to the officers terminated the proceedings.

All future meetings will be held at the Addison Hall, W., on the second and fourth Fridays in the month.

Intending members are requested to communicate with the Secretary, Mr. John A. Hodges, 87, Chancery-lane.

Next meeting on Friday, October 25, at eight. Address by the new President, Mr. Charles Bilton, followed by exhibition of slides in optical lantern. Members are requested to bring slides. Friends are invited.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

OCTOBER 4.—The President (Mr. F. W. Edwards) in the chair.

Mr. Tollet was elected a member.

The Treasurer (Mr. H. Banks) has placed at the disposal of the Committee a silver medal for competition at the exhibition to be held in January, 1890.

The PRESIDENT delivered an address on *Lenses*, illustrating the uses and capabilities by sample prints taken by the various lenses. Amongst them was one of some machinery, the negative of which had received ten hours' exposure. The meetings will in future be held on the first and third Fridays in the month.

Subject for next meeting, October 18, *Lantern Slide Making*.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

OCTOBER 9.—Mr. S. S. Partridge (Vice-President) in the chair.

Mr. F. PIERPOINT delivered a lecture on *A Trip up the Thames from Oxford to London Bridge*, illustrated by slides from negatives taken en route.

IPSWICH PHOTOGRAPHIC SOCIETY.

OCTOBER 8.—Mr. J. C. Wiggin in the chair.

The subject of the evening was *Lantern Slides*, opened by a paper from Messrs. Cash and Pringle, which they illustrated by a number of slides exposed chiefly to magnesium ribbon of varying lengths, from one to twelve inches, and developed with various developers. They also exhibited and explained the working of a lantern for illuminating negatives by magnesium ribbon for reduction in the camera, made according to the instructions given in an editorial article in THE BRITISH JOURNAL OF PHOTOGRAPHY some two years ago, and which they had found very useful.

Mr. F. W. Woodcock also exhibited slides made by him.

Mr. Wiggin exhibited Blair's patent camera, feather-weight slides and tripod, and two frames of lantern slides.

The next monthly meeting will be November 12, for which the *Illustrated Boston* slides have been secured.

SHEFFIELD CAMERA CLUB.

OCTOBER 11.—Dr. T. H. Morton (President) in the chair.

A number of pleasing views obtained by the members at the late excursion to Conisborough were exhibited, including several taken by Mr. Taylor with a Rouch's detective camera.

Mr. H. J. HARDY, F.C.S. (Hon. Secretary), read a paper on *The Chemistry of Photography*. The lecturer said that photography was a subject of vast proportions, and might be conveniently divided into two sections—one embracing technical art, and the other science. He thought the art side had been made more prominent, but we should not allow a scientific discovery to degenerate into a purely empirical art. Many of the industries have lost or remained stationary by working by rule of thumb. Art ought not to outstrip science, and the branches of photography would be advanced by the scientific aspect. The action of light on certain bodies produced a physical or chemical change, sometimes both. The action of light on sulphur effected a change in the crystalline structure, but no chemical action; in others a disassociation of the constituents is effected, as in certain salts of silver; chemical changes or decompositions also take place uninfluenced by light. Examples of photochemical action on the salts of silver, iron, gold, also chromates and bitumen, were described and the formulae traced on the blackboard. The theory of some changes in haloid salts forming the photographic image were as yet obscure, but the researches of Captain Abney and others were tending to their elucidation.

A discussion followed, in which the President, Mr. W. Gilley, and Mr. E. Howarth, F.R.A.S., took part.

DERBY PHOTOGRAPHIC SOCIETY.

OCTOBER 8.—The following were elected officers for 1890:—*President*: Captain W. de W. Abney, C.B., R.E., F.R.S., &c.—*Vice-Presidents*: Messrs. C. Bourdin, R. Keene, and T. Scotton.—*Committee*: Messrs. F. Cooper, J. A. Cope, C. B. Keene, E. J. Lovejoy, R. L. Warham, and R. Woods.—*Auditors*: Messrs. F. Hyde and J. Riches.—*Treasurer*: A. B. Hamilton.—*Hon. Secretary*: C. J. Chadwick, Sydney-villas, Mill Hill-road.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

OCTOBER 10.—Mr. W. J. Harrison, F.G.S., in the chair.

Mr. W. L. Hipwell was elected a member.

The Hon. Secretary read the award of the Judge, Mr. G. Baukart, for the prize for the best three pictures (one upright) taken at the Dovedale excursion, which was given to "Ilford Ordinary," and on opening the sealed envelopes it was found to be Mr. E. C. Middleton.

The remainder of the evening was devoted to a discussion on *Lenses and their Uses*. The subject was introduced by Mr. Walter Griffiths [this will appear subsequently].

On Wednesday, the 9th instant, the Vesey Club, Sutton Coldfield, invited the Birmingham Photographic Society to a special meeting of their Club. A number of members attended, and Messrs. Horton, Harrison, Jaques, and Middleton, gave papers, &c., epitomising the several developments of photography, viz., Daguerreotype, collodion and gelatine emulsion, &c., paper printing, and photo-mechanical processes. A pleasant evening was spent, and a resolution was proposed—"That the Vesey Club approve of the suggested photo-survey of the county of Warwick, and would be willing to aid the Birmingham Photographic Society in the way of recording geological, botanical, or other scientific matter of interest, and by using its influence in carrying out so desirable a project."

The Mayor of Sutton and Vice-President of the Vesey Club, Mr. J. B. Stone, J.P., gave a *conversazione* in the Town Hall, Sutton Coldfield, on the 12th instant, at which he exhibited a portion of his large collection of photographs, 15x12 and upwards, of American and Continental views, supplemented with a number of photographs from the members of the Birmingham Photographic Society and others.

A lantern display was given by the Lantern Committee of the Birmingham Photographic Society, Mr. E. H. Jaques showing his Norway series and Mr. J. C. Fowler the Society's slides.

Some two hundred and fifty friends and members were present, and the entertainment was much appreciated; and the Mayor remarked that the two Societies might work together with mutual benefit in the cause of science.

NOTTINGHAMSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.

OCTOBER 7.—Mr. G. A. Bull in the chair. The report of the Secretary for the past year showed that an innovation was the Saturday night reunions, which were well attended during the winter months; much useful information being thereby brought before the notice of young beginners by means of the magnesium flash-light experiments, demonstrations in development, the showing of apparatus and novelties. During the past year seventeen new members have been enrolled, while five have withdrawn, leaving a total of sixty-eight. Twenty ordinary meetings of the Association have been held during the year.

The following officers were elected for the ensuing year:—*President*: Mr. G. A. Bull. — *Vice-Presidents*: Messrs. S. Wells and I. Turley Lewis. — *Committee*: Messrs. R. S. Armitage, T. Carmell, Dr. W. T. Crew, Mr. Marriott, Messrs. A. Pickard, T. S. Piggia, J. Spray, M. Tugnet, G. E. Smith, G. E. Williamson, H. A. A. Wigley, W. Towers. — *Hon. Treasurer*: Mr. B. Sturges Dodd. — *Hon. Secretary*: Mr. P. E. Knight.

THE SOCIETY OF FRIENDS OF PHOTOGRAPHY IN BRESLAU.

THE above Society has developed a considerable degree of activity during the past year, holding no less than seven general meetings during the summer. At one of these, which took place in June, it was determined to arrange a special complimentary meeting in honour of Professor Schirn, the newly elected President of the Society, and this was accordingly the character of the last meeting.

The technical portion of the sitting took the form of a number of interesting debates, which were illustrated by experiments and exhibits. Both hydroquinone, elkonogen, and Dr. Werner's universal developer, were much discussed, but, nevertheless, a number of members excited some interest by stoutly maintaining the oxalate developer to be superior to them all.

Prof. Dr. HERMANN COHN and Prof. Dr. LEONHARD WEBER read papers which excited considerable interest. The former gave a description of his rhomboid camera, and the latter exhibited some photographs of lightning, which he had taken on the morning of July 2 last. Instead of keeping the camera stationary when these photographs were taken it was given a shaking, oscillatory motion; by this simple means light is thrown upon the duration of the flash. A rapid flash will, of course, appear as a sharp line even when the camera is in motion, while flashes that pass slowly will produce a band crossed by lines corresponding to the bright points in the flash. The result was to show that one of the flashes continued for nearly half a second continuously and uniformly bright from end to end; another flash took up about the same length of time, but during the first tenth of the period three sudden increments of intensity displayed themselves, which appeared on the plate as three parallel zigzag lines.

The membership of the Society has increased considerably during the last few months, the number now being seventy-four.

Correspondence.

✽✽ Correspondents should never write on both sides of the paper.

NUKTIGONIA AND DAYLIGHT DEVELOPMENT.

To the Editor.

SIR,—If your correspondent, Mr. Hanson, will refer to your issue of February 1, 1889, on page 77 he will find a method of developing without the aid of a dark room was demonstrated by me at the meeting of the

Manchester Photographic Society held in January. My first experiments, some ten years ago, was with ferrous oxalate, but I soon discovered that the plate could not be examined out of developing solution. I then made dishes with yellow glass bottoms, designed with a well on one side to receive developer when held vertically, and with a yellow glass cover I was able fairly well to watch development. It was, however, rather difficult to judge the fine detail.

By the process given on page 77 of this year's BRITISH JOURNAL OF PHOTOGRAPHY, the film is stained a deep ruby by the dyed water before development commences, and during development the plate can be lifted out and examined. I advise care in not exposing the plate to too strong a light. If daylight, let it be subdued borrowed light, or gaslight some distance from it. The stained film, with washing after fixing, will be colourless. —I am, yours, &c.,

JOHN SCHOFIELD.

Heaton Mersey, near Manchester, October 15, 1889.

THE CARDIFF EXHIBITION.

To the Editor.

SIR,—Owing to a printer's error in our catalogue, we find that our list of awards in same is not correct. In Class 16, No. 10, please substitute Mr. A. Nicholson as winner of the silver medal in place of Mr. H. E. Brown.—I am, yours, &c.,

G. H. BEDFORD, Hon. Secretary.

Cardiff, October 16.

Exchange Column.

. No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

I will exchange a cabinet portrait lens, by Millet, for two flatted backgrounds, interior and exterior.—Address, G., 7, Hillside-villa, Hornsey, N.

Wanted, half-plate camera and lens or detective set, in exchange for Clinton cocca-wood flute and Nicholson's tutor.—Address, J. R. HILDER, Matlock Bath.

Will exchange quarter-plate camera, by Shew, with case, three double slides, lens, and stand, for half-plate portrait lens by good maker.—Address, W. R. FAIRBY, Harrold, Bedford.

Wanted, quarter-plate detective camera; exchange, gas bag, safety jet, pressure board, safety retort, and purifier, &c.—Address, J. W. COPELY, 162, Carr-road, Sheffield.

I will exchange 12x10 camera, swing back, Ross' lens, and one double slide, for lathe, five-inch centre, six-feet six-inch bed.—Address, E. A. CARNELL, 24, Moorgate-street, Nottingham.

I will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, 1888 complete, and five volumes incomplete, for half-plate camera and slide.—Address, F. M., 67, Trintalgar-road, Old Kent-road, S.E.

THE BRITISH JOURNAL OF PHOTOGRAPHY for 1884, 1887, 1888, with others; also ALMANACH and Year-Books. Wanted, pneumatic time shutter, burnisher, or cameo press.—Address, MANAGER, 6, Prospect-terrace, Hounslow.

I will exchange whole-plate camera with slides and lens, an exterior and a plain background, balustrade, cabinet burnisher, and two chairs, for 24x18 portable camera with backs.—Address, ARTIST, 39, Goldsmith-street, Nottingham.

Exchange, three slide slips (paper), one paper vignette background, one landscape ditto (linen), rustic stile, and rapid rectilinear lens, eight-inch focus. Want pneumatic shutter.—Address, W. C. CRYEER, 39, Highgate Hill, N.

Wanted, half-plate camera with double slides or short-focus cabinet portrait lens, in exchange for a Gem and Victoria camera. Takes thirty-six Gems or nine Victorias on one plate.—Address, J. B. SMITHSON, Photographer, Leyburn, Yorkshire.

Answers to Correspondents.

. Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

J. Holloway, Cheltenham.—One photograph of Miss Amy Coleridge and Mr. Kenneth Black. Five photographs of Miss Amy Coleridge. One photograph of Miss De Silva. One photograph of Mr. Maria Harvey.

E. E. Hibling, Malden.—Photograph of F. W. S. Cornwallis, M.P.

G. F. Blackmore, Hammersmith.—Photograph entitled "The Silver Lining."

M. STAPLETON, J. C. B., MEALY, and others.—See sub-leader in the present number.

F. LAWS.—For articles on the dusting-on process, see pages 417, 433, and 449 of our last volume.

- S. S. S.—We are quite familiar with the picture; it is an ordinary chromolithograph produced in Germany.
- LUX (Manchester).—Commence by studying Ganot's *Physics*, which will prove the keystone to the other branches.
- B. UNTHANK.—Refer to the recent articles on *Economy in the Printing Room*; they give all the information sought for.
- R. JORDAN.—There is no English edition of the work published. The German one can be obtained through a foreign bookseller.
- A SUBSCRIBER.—Even if you tone and fix by one bath it is better that the prints should have a final treatment in fresh hyposulphite solution.
- M. WARNE.—Filter the solution and try it. If it does not then work well, add some carbonate of soda and sun it for two or three days. This will probably set matters right.
- A. METHVEN.—For such subjects no very great advantage would be gained by adopting orthochromatic photography. Slow plates are better for this class of work than rapid ones.
- W. E. DAVIES.—The yellowness in the examples sent is caused by imperfect fixation. Either the "hypo" solution was too weak or the time of immersion too short. The short washing was not the cause. We have not tried paper of the brand mentioned.
- G. JONES.—The object of the special mounting is to enable the front lens of the combination to be used as a landscape lens. The front portion, after the hinder portion is removed, is screwed into the flange, a diaphragm being inserted at the outer end.
- F. S. SPILLER.—It is impossible for us to say by what process a print was produced simply by seeing the paper from which the image has been cleaned off. If we had seen the print before it had been tampered with we should have been in a position to form an opinion.
- C. W. HARRIS.—In the solid double dark slides mentioned the plates are inserted in a moveable partition which slides in a recess provided for it. We have not yet seen the *Cabinet Gallery of Celebrities*, but when we do we shall probably be enabled to guess at the process employed.
- W. S. CARPENTER.—The collotype is not a patented process, and the patent for the Woodburytype process has long since expired. Several patents exist for photo-mechanical printing, however, but the most successful workers in this direction keep the methods they employ as strict trade secrets.
- E. MEARS wishes to know where he can obtain some of the Causon paper, which was said some years ago to be so well suited to photographic purposes. —The paper in question is not at the present time being manufactured. The manufacture of Causon photographic paper ceased many years ago.
- X. Y. Z.—Apply to the Platinotype Company. Mr. F. W. Edwards, 87, Rellinder-road, Peckham, will possibly give you lessons in platinotype printing. Ceramic photographs are produced by Mr. Walery, Regent-street, Mr. Faulkner, of Baker-street, and Mr. Tunny, of Edinburgh. Examples may be seen at their establishments.
- COLOUR.—A knowledge of both water and oil colouring is exceedingly useful to a photographer. It is difficult to advise you as to which is preferable without knowing the kind of business you follow. Oil painting is best adapted for large work, and water-colour for small; but either is an acquisition.
- LANDSCAPE.—Messrs. Negretti & Zambra have the sole right of photographing in the Crystal Palace and the grounds; therefore you will not be permitted to take photographs of the extinct animals without their consent, and it is very doubtful if that would be granted. Possibly, however, the firm would take the negatives for you as a matter of business. Write them.
- H. L. MOREL.—If you exhibit a portrait to the annoyance of the sitter we imagine you can be restrained by injunction from one of the superior Courts. Of course, apart from the legal part of the question, you have no moral right to use any portrait you have taken in the ordinary course of business for purposes of your own. Doing so against the wish of the customer is an unwise proceeding under any circumstances.
- J. R. CARDWELL.—We cannot give the formula by which the commercial plates mentioned are prepared, as the makers have not published it. Several excellent formulae for emulsions, and the methods of preparing them, have appeared in past *ALMANACS*, and you cannot do better than refer to them, as we cannot afford space to repeat what is so easily referred to elsewhere. With any formula it is very doubtful if good plates can be manufactured at the price mentioned.
- S. J. B., anent the recent article referring to the chromotype process as being a "neglected one," says that one reason why it has become so is that the tissue could only be obtained by those who paid a heavy fee to use it.—This was the case, but it was well known that any ordinary commercial carbon tissue would answer quite as well. The difference was only in the tint, and this was approached very closely by some of the tissues which any one could obtain in the market.
- P. M. PRINTER (New South Wales).—Judging from the examples sent, the failure appears to be due rather to manipulation than formula; therefore, without seeing the working it is difficult to advise. It would seem, however, in the collotype that the inking was at fault. Either the thick ink was too thin or the thin ink too thick, so that it becomes partially removed in the second inking. As no description whatever is given of the method of procedure, it is impossible to give a definite opinion. Send further details, and we will endeavour to assist you. Thanks for kind offer.

- G. B. BRADSHAW.—We are not acquainted with the work of the maker named, and, further, are not aware of the terms upon which he conducts his business. See conditions for exchanges.
- R. HENDERSON says: "I shall feel obliged if you will give me an answer to the following question in your inquiry column:—I engaged an artist to paint me a number of large dioramic pictures, all landscapes. Some of them are from my own photographs and some from his own sketches. Can I legally copy the pictures, either with a camera or on canvas, or does the artist hold the copyright? May say that I found everything, also studio to paint in, the artist only supplying the labour."—Unless there is an agreement to the contrary the copyright is vested in the author of the work. The artist retains the copyright in his work, while the photographer retains it in his photographs.
- D. C. J. says: "One or two photographers I know make it a rule to mount all their portraits—that is, their customers' portraits—on mounts stamped 'copyright.' If one of these portraits is brought to me to copy, shall I render myself liable to any penalty, I knowing quite well that the pictures have not been registered, as they are ordinary sitters' portraits?"—If no copyright exists there is none to be infringed, hence there can be no penalty. We know that some photographers habitually mark their customers' portraits "copyright," but it is an illegal act. It is quite as illegal to mark anything copyright when it is not copyright, as to mark a thing as patent when it is not patented. The penalty for doing this is very heavy.
- J. BARTON writes: "If in your 'Answers to Correspondents' you will give 'Young Operator' some advice as to the taking of large heads, from three and a half to four-inch vignettes, shall feel deeply grateful; have tried with Dallmeyer cabinet lens stopped down, but the result is not at all satisfactory to self or employer: must they be lighted differently from ordinary work?"—Large heads require careful lighting, though not differing from small ones. As a matter of course, in the larger size, any errors in lighting become more conspicuous than they would be in a smaller one. We should scarcely expect that you would get satisfactory four-inch heads with a cabinet lens, unless it be of much longer focus than usual. See Mr. Dallmeyer's paper read at the recent Convention.
- FRYOLINE writes: "I have, up till lately, had most capital results with the acetate of soda toning bath, but now somehow I cannot get one to work right at all. I have mixed fresh ones and likewise different strengths, also kept one a matter of months before using, but of no avail. The trouble is that they (the prints) after a space of three-quarters of an hour take the colour of a most miserable, dirty red; if I continue the toning the result is a mealy bleaching takes place round the edges. I may add that I have tried new gold and also a fresh sample of soda (acetate), but still failure—can you explain the trouble? Could you give me a formula for a bath to tone about two sheets at a time (I like the purple tones), also advise me as to what paints to get for colouring landscapes? I enclose print fixed but not washed. All prints turn out the same."—The fault in the print forwarded is that it is very much over-toned. Had the print been removed at a much earlier stage, it would doubtless have been of a good tone. The bath was not at fault; any other would have yielded a similar result with the same treatment. See sub-leader. Ordinary water-colours, such as those sold by the artists' colourmen.

THE new catalogue of Mr. J. R. Gotz, 19 Buckingham-street, W.C., differs from many others in this respect, that it contains only such specialities as are manufactured by himself or are imported by him, and for which he holds the sole agency. Almost naturally the first place is given to the Aplanatic series of lenses by Suter of Basle, a series that is growing both numerically and quantitatively, and particulars concerning some of which we have on former occasions made our readers aware. Such shutters as the "Volnte" and the "Wing" also find place, together with his patent camera; the bromide and orthochromatic plates of Vogel and Obernetter; the chloride and bromide papers of Drs. Obernetter and Just; and various papers of the ferro-prussiate, ferridcyanide, and ferrogallie class.

SPIRIT PHOTOGRAPHY—A CHALLENGE.—From the report of the Spiritualistic Congress at Paris we learn that the subject of spirit photography has been prominently brought forward at this convention. The Secretary-General, speaking of certain spirit photographs taken by Captain Volpi, says:—"In his experiments, impartially carried on for five years, Captain Volpi took every necessary precaution. He has arrived at such results that true spirit photography cannot be imitated by any of the means at present known. This is due to the action of a special modification of the light made by the apparition, a modification of such a nature that Captain Volpi has offered five hundred francs to the photographer who succeeds in imitating one of his spirit photographs by any fraudulent means whatever. Many photographers have tried; all have asserted that the phenomena cannot be imitated."

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1538. VOL. XXXVI.—OCTOBER 25, 1889.

TONING BY PLATINUM.

It will be remembered that in our issue of April 12 of the present year Mr. Lyonel Clark published a method of toning by platinum salts, in which quite a new departure from any previous system had been made.

Chemically speaking, it consists in employing platinous instead of platinic salts. Artistically, it yields prints of a rich black, yet which at will may partake of quite warm tones. As regards the time involved in the operation very few seconds indeed suffice to effect the toning.

Those who were present at the Camera Club on Thursday last week and witnessed the successful demonstration of the process given by Mr. Clark could scarcely fail to be struck with the general efficiency of this method of toning. The prints, which were on plain paper, in contradistinction to albumenised paper, were considerably over-printed, so as to ensure a generous amount of silver being in the image formed in the printing frame.

Pending the publication of Mr. Clark's lecture, we may here state the hypothesis upon which he based his experiments. Chloride of platinum, or that substance by whichever of some other names it is known, is acid, and the free hydrochloric acid attacks the silver image; if neutralised it refuses to tone, being in this respect unlike gold. It has, therefore, to be acidified by some other acid, remaining still in the platinic state. Having certain deductions strengthened by Captain Pizzighelli's statement that silver is an equally good reducer of the platinous salts as iron, he printed on ordinary plain salted paper, washed it to get rid of the free silver, then laid it down on a plate of glass and brushed it over with the ordinary solution recommended by Mr. Willis for developing with the cold bath platina process. The red of the silver image changed to platinum black with the same rapidity as does the iron-coated paper of the Platinotype Company.

It is not pretended that the image formed by substitution of platinum for silver possesses stability equalling that of the platinum process of Willis, as it, in common with gold-toned prints, succumbs to destructive agents, such as chlorine, which have no appreciable effect upon pure platinotypes; but it possesses certain advantages *sui generis*. Among the chief of these may be mentioned that of observing in the reduced silver image the progress of the printing, which affords facilities when any double printing is to be performed on one sheet; another advantage is, that whereas with the ordinary platinum process the image is developed at once to that tint known as the platinum tone, with this it may be arrested at any stage between the red of the silver and the black of the platinum. We have spoken of the rapidity with which the toning was

effected when the demonstration in question was given, but such rapidity is not necessarily a concomitant of the process, for by keeping the solution colder than was the case when this demonstration was given, and possibly also somewhat weaker, there is no doubt that the progress may be rendered sufficiently slow to admit of the action being stopped whenever desired. The ordinary silver printer has nothing to unlearn, as everything up to the toning is effected in the usual way, only this being noted that the printing has to be carried deeper than usual.

After we publish Mr. Clark's lecture we shall probably have more to say anent this new method of toning.

NEGLECTED PROCESSES.—COLLODION TRANSFERS— PHOTO-CRAYONS.

THE term "collodion transfer" is now usually associated with cheap so-called club portraits—cold and inky in tone, and generally wretchedly coloured in oil colours. The process, as most of our readers are aware, consists in making a transparency by wet collodion on glass, and then transferring the film on to gelatinised paper. Bromide paper has now, however, generally superseded this process for cheap pictures.

The usual type of collodion transfers were, as just mentioned, of an unpleasant cold tone and very inartistic. But this was not the fault of the process itself, but of its workers. For, as a matter of fact, it was, and is, in skilful hands, capable of yielding excellent results. The late Mr. Jabez Hughes employed it extensively, and, if we mistake not, the greater number of the enlargements issued from his establishment were by this process. There was no unpleasant tone in them, as they were all of a rich, warm black. This, we believe, Mr. Hughes obtained by toning the image with a chloride of platinum, or of palladium, according to requirements. As the enlargement in this process—as in the case with bromide paper—is made direct from the negative, and not through an intermediate transparency, the utmost possible sharpness is secured.

The collodion transfer process—long before it was applied to enlargements—was somewhat extensively employed, by one house at least, that of Mr. Disderi, as an expeditious means of producing large numbers of prints for publication. During the period of the "Carte mania," Mr. Disderi issued many thousands of portraits by this process, and excellent they were. The paper employed by him was, however, somewhat different from that employed more recently. It was a surfaced paper, similar to that used in lithography, and this gave the prints a far better appearance than those on plain gelatinised paper.

The photo-crayon process was one introduced and patented by the late Mr. Oliver Sarony about twenty years back. In principle it was somewhat analogous to the collodion transfer process, except that the film, instead of being transferred, remained upon the glass. But, in this case, the image had to be very much thinner; indeed, quite a phantom one when viewed by transmitted light. Usually the enlargement was made about fifteen inches by twelve, and always vignettted. After the thin transparency was finished it was varnished, and then backed up with rough drawing paper, usually tinted, such as that used for crayon drawings. Upon this backing paper were some sketchily hatched lines, either made with a black crayon or printed upon it by lithography. The chief claim in the patent, it may be mentioned, was for the production of the hatching by lithography. This hatching was very slight, and could be done in a minute or two. It was put on the paper in such a position that it would show just where the figure was vignettted off, and nowhere else. This was all the hand work there was upon the picture.

Photo-crayon pictures were framed in the same style as crayon drawings, and although they had really no hand work upon them, they had, when good, all the appearance of highly finished crayon drawings. No one would for a moment suspect that the image was on a glass plate. We remember well when Mr. Sarony showed his first examples at a meeting of the Photographic Society, many of the members present would scarcely believe they were actually on glass until one or two of them were taken to pieces. When this fact is mentioned it will be fully realised that the pictures were very effective, while they cost little, or no more, to produce than the common collodion transfers; indeed, the photo-crayon was beyond question the best process for obtaining an artistic and effective enlargement at a small cost, and in this respect it is not yet surpassed. Although so cheaply produced, the usual sum obtained for the pictures was two and a half guineas, and they were regarded as good value for the money. Some artists we know realised large sums for two or three seasons by their introduction. In this method, it will be noted, the paper was not in optical contact with the image. If it were, the drawing-like effect would have been entirely absent. Sometimes a little flesh colour was stumped on that portion of the paper beneath the face with good effect.

With qualities such as those above described the question with most people will be, "Why is it that this process has to be classed amongst the neglected ones?" One of the principal reasons is this. The pictures soon got into ill repute on account of many instances of fugitiveness. It required considerable skill to produce the pictures of the proper colour direct, for it was necessary that the image should be of a warm, black tone, which was not easy to secure in the development alone, but it could be most readily obtained by toning with mercury, the plan recommended by the introducer. However, in the way this method of toning was usually employed the image proved evanescent when long exposed to the light; but the pictures were permanent enough if left untoned; so they were if they were toned with gold or platinum. We have several examples by us now that were toned with gold which are all as good as when they were first produced, notwithstanding that they are nearly twenty years old.

The process, as it used to be worked, necessitated a knowledge of the wet collodion process, and considerable skill in its manipulation, but there are other methods by which the pictures could be produced. We have seen some very effective

photo-crayons done by the carbon process, the image being developed on glass. But this method necessitates the making of a transparency and also an enlarged negative.

If photo-crayon pictures were required at the present time, the simplest way of producing them to most operators would be with the Eastman transferotype paper. With this paper the enlargement would be made in the ordinary manner, keeping the image rather thinner than usual in the development and of a somewhat warm, black tone. After fixing, the film would be transferred to a glass plate, and there allowed to dry. All that then remains is to back the picture with the hatched drawing paper and frame it. The work is then completed. By this method very effective pictures could be produced at a minimum of cost.

MR. WALTER GARDINER'S paper, read at the British Association meeting, gives us quite a new aspect of nature printing. It might be said that "every schoolboy" has made photographs of leaves by printing on sensitised paper with some pretty leaf as his negative, a piece of a broken window-pane his probable printing frame, and has, at times, varied his results by using a piece of lace in lieu of the leaf; but in Mr. Gardiner's process the leaf itself is the "sensitive paper," and his method of printing involves a process of development. Under the action of light, starch is formed in the leaves of a plant, and the well-known reaction of starch and iodine forms the leading idea of the development. If a plant (preferably one with thin leaves) be placed in the dark overnight, and then brought out into the light next morning, the selected leaves being covered with a sharp negative, starch is formed when light is transmitted, and in greatest quantity in the brightest areas. Thus a positive in starch is produced which is capable of development by suitable treatment with iodine. Mr. Gardiner showed that, by suitable washing and treatment with a soluble silver salt to produce silver iodide, a permanent print might be obtained.

THE annoyance of the continual offensive odour given off by unsuitable indiarubber tube connexions attached to gas burners, &c., owing to the permeation of the gas through the wall of indiarubber, is too well known to need description, and many ways of preventing it have been devised. Mr. Fletcher's plan of, in effect, fitting two tubes one within the other, with a coating of tin foil between to arrest the osmose of the gas, is well known; but such tubing is not so readily purchasable as the ordinary kind, and is rather costly. If red rubber of the heaviest make is used a considerable time elapses before the gas is perceptible to the organs of smell; the usual thin rubber with coiled iron wire inside is most objectionable. A plan for treating flexible tube, published in the current number of the *Chemical News*, seems to be of great promise. It consists in the use of concentric tubes separated, not by metal, but by water.

THE method of construction is as follows: "A length of small rubber tube is drawn through another tube of equal length but of greater diameter; each end is finished with a small length of glass tube fitting the smaller tube; one end is bound off with cord, then the space between the inner and outer tube is filled with water, or any liquid required; the other end is then bound off. By this means a water-jacketed flexible tube is easily constructed."

WHEN conversing the other day with Mr. A. L. Henderson, who has just returned from his trip to the antipodes, he informed us that both in Australia and in New Zealand landscape photography has acquired a very high degree of excellence. This he thinks is to be attributed in a large measure to the singular purity of the atmosphere.

"LA NATURE" last week gave an illustrated account of a new application of photography: the photographing of Newton's rings and other phenomena of diffraction not capable of reproduction by the ordinary agency of the camera and lens. By using a lens of $f/4$ rapidity, with

isochromatic plates, and dispensing with a reflector, eight to ten minutes sufficed to obtain a good negative when the source of light was M. Carie's monochromatic sodium lamp. This illuminator is made by placing perfectly dried chloride of sodium at the bottom of a vessel fitted at its upper part with an exterior gas jet, and provided with an interior jet, through which the gas gains admittance, shaking up and carrying forward the dry powder as it is injected through the inner jet. An illustration is given of the same class of results when obtained by a thallium light. It is stated that the duration of the exposure is only one-thirtieth of that required with the sodium light. It is pointed out that by means of this method of photography it is possible to measure the relative lengths of the light waves of the two substances, and generally of other wave lengths.

THE proceedings of the Astro-Photographic Conference which sat last month in Paris are not yet published; but among the points decided by the Permanent Committee the following will be found:—Plate glass only must be used for the plates; the make of plate or mode of preparation is left to the astronomer, but the same kind is to be employed for the chart and the catalogue, the grating or network to be used with both series. At the same time, a series of standard plates will be prepared by the Paris Observatory, and the time of exposure must be so adjusted as to compare with these standards, *bureau* being established for comparing the plate when the Observatory staff cannot accomplish it. The dimensions of plate are to be 160 millimetres square, the size of the field being two degrees square, and an overlapping of five minutes being decided upon.

It may be worth while in this connexion quoting the opinion of Dr. Elkin, of the Winchester Observatory, Yale College, upon the value of photography in astronomy, based upon his examination of already recorded observations. He arrived at the conclusion that the smallness of the probable errors he had found were "convincing proof" that in photography we had a means of investigation for micrometric work which was at least equal to any existing method as regards magnitude, and far surpassing other methods in "ease of measurement and output of work."

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

No. IV.

ELLIOTT & SON (No. 403), *Mrs. Alice Shaw*.—An enlarged portrait of the "whistling lady." This work is not the outcome of one plate, but is a very noteworthy specimen of photographic ingenuity. Three negatives have been utilised for the picture, and the interest is increased by the uniformity of tone and colour which has resulted.

R. H. Lord (No. 438), *Try Again*.—A large picture, 24 × 20, of an interior filled with details of an old-fashioned large living room; the housewife is attempting to run some cotton through a needle, whilst the good man, resting after work, with a glass in hand, addresses the good wife in the title "try again." This picture has been carefully studied for detail, the two figures having been taken on separate negatives, and is a noteworthy example of design so far well carried out. But the thought arises, If photography can be used to depict the ordinary every-day life, why should it not also attempt the beautiful and occasionally more poetic aspect? Without doubt it can do this, but the more ambitious the design, so the greater must be the artistic faculty which conceives, arranges, and then secures the photographic resemblance. Hence this picture, which is an excellent scientific record of facts, stops there; in fact, it is too literal. It wants the glamour of much of the detail being kept back from so prominently asserting itself. Now, as this can be done, here arises the necessity of artistic capability and culture, so as to master the conditions necessary for the production of a picture by photography.

Ralph W. Robinson (No. 482), *Grace*.—A picture where a higher sentiment has pervaded the attempt to photograph emotion—a grandmother saying grace at table with her granddaughter. The position of the old lady is very good, but the child should not have looked at her; it disturbs the repose which would have better suited the subject, and there is also a repetition of some of the square lines of the com-

position which do not aid the sentiment. This exhibitor appears to have given all his energies to the excellent series of portraits of the R.A.s, which must overbalance any little shortcomings in this attempt at a good subject.

Adam Diston (No. 524), *Memories*.—This is a very small photograph, containing much of this exhibitor's low tones in treatment which latterly have pervaded his work, and this is strengthened by the photograph being surrounded by a very wide gold frame, the light upon which also increases the gloom of the prints; so that whilst fully appreciating the attempt to raise photographic art, which this exhibitor has always done, we hardly sympathise with the present study, which does not, after all, appeal so much to our sympathies as it does to our reason to know why these memories should be associated with so much darkness. The combination of lines and study of detail have been very carefully thought about, but the result scarcely justifies the presentment of such a subject in so gloomy a tone.

William Parry (Nos. 543, 580, and 587).—These are very good photographs of steam warships in motion. No. 587, *H.M.S. Victoria*, is also a picture where thought has been exercised at the precise moment when the vessel was in a good position to make an effective rendering; this will be evident when the light and dark portions of the vessel, together with its background (a bridge), are studied. The smoke from a vessel (not seen) helps this good effect, so that, besides being a very perfect record, it also evinces thought and design at the right moment, when the combination of objects conduce to form a very charming picture.

A. Donald (Nos. 566 and 571).—Two 10 × 8 pictures, evincing a thoughtful study of position. No. 566, *Who's That?*—an old housewife sitting at her fireside turns on the intruder and puts the question in the title. Here there is shown great attention to the combinations of form, in the good arrangement of position, and the lines of the drapery. The same remarks will also apply to No. 571, *Where's my Specs?* In this picture the good wife, standing at a table, is searching her basket for the specs, which have got up to her forehead. In these two photographs, which possess the valuable attribute of the subjugation of the background (with accessories) to the figures, the attention fixes upon the faces of the women, which is just what art endeavours to realise.

T. M. Brownrigg (Nos. 19, 42, and 44).—The first picture is a figure study of an old foreign country woman ninety years old sitting and engaged in plying a distaff; the position is very easy and well arranged, but why such an intensely dark background? This, with some rambling bits of light running over the other parts, rather interferes with an otherwise well-arranged study. Nos. 42 and 44 are *Scenes on the Dart*, which contain the usual good work of this careful manipulator; but the choice of natural arrangement is not quite so successful as could be wished, as there are certain straight lines in the landscapes which interfere ungracefully with the composition; also the general effect would have been increased if some more powerful bits of dark could have been produced.

F. Whaley (No. 47), *Your Turn Next, Sir*.—This is a large composition picture, 24 × 18, from two or more negatives, the arrangement of which has been very carefully thought about, and the play of light and dark effects judiciously arranged; but what a subject!—a barber shaving a customer, whilst five others await their turn for hair cutting, &c. We have again and again referred to the great necessity that exists for raising photography above its normal capacity for facsimile work. And here we have a pictorial realisation of an event which should always be kept in the background. A vast amount of skill and aptitude for design is here shown which should be employed upon better subjects.

Lyddell Sawyer (Nos. 52 to 56, and 82 to 86).—The whole of the ten exhibits, the work of this clever photographer, show very distinctly a good capacity for art work, especially in the choice of position of figures, as also in several pictures where ships form the main point of interest. These various subjects deserve praise alone for the indefatigable industry shown in bringing each picture to an artistic point and a photographic production. In every one of these pictures there is life, and they all have been chosen with possibilities of near, midway, and far-off studies, which give these remarkably bright scenes the notion of having been photographed from paintings.

More we cannot say in their praise, but (and it must be alluded to) the brush work reveals weak spots, which, if absolutely necessary, should be done by some one who can mingle the two in better harmony.

G. West & Son (Nos. 57, and five other *Yacht Studies*).—These pictures are each shown in a separate frame, a great improvement upon the mixed condition of past exhibits—it shows great command of the means used to be able to photograph under such conditions. At the same time, we think they do not form so pictorial a series as hitherto have been seen, for the beauty in the real thing consists in contrast between the sails almost in the water and then nearly upright again, or a decided movement one way or another, which these photographs do not give. Hence we think the limits of horizontal sailing have been reached, and richer effects may be secured from yachts not quite subject to such strong winds.

Abel Lewis (Nos. 49 and 80).—The first is a *Young Lady with Violin*—a very effective picture, being almost full length; but why place the violin in position for being played upon, whilst the bow is turned down at rest on the figure?—two opposite positions, which a violin player would never assume. Also the powerful shadow of some of the forms on the wall are not pleasant, being ugly in form and dark in tone. The second (No. 80) is very good in treatment, with one exception—the left arm, with the hand not seen and the elbow on the wall, forms a distinct right angle with the other arm, which is very nicely posed. Despite these serious objections, the pictures, nevertheless, show a decided advance in treatment; there prevails a bright and sunny tone about these exhibits which raises them far above the beaten track.

B. Gay Wilkinson (Nos. 100, 102, 103, and 104).—Four pictures, completing the series sent in by this exhibitor—two of which, having been awarded a medal, have already been noticed. All these possess very much of the good qualities referred to in the chosen pictures for award, but in these we have some existing conditions which, when not overcome, do not help the artistic result; we mean the coming forward of background trees, which utterly repel any attempt to subdue them. These conditions were not in the two pictures alluded to, so they have fortunately (guided by taste) escaped the evils which dark foliage is subjected to.

D. R. Clark, M.A. (No. 123), *Wires and Weans Ashore*.—A peculiar good effect has been produced in this picture by the brightness of the lights, which very clearly suggest a burning hot sun. Whether this effect has been produced by design or not, the result is very good, and opens up many possibilities of good effect being obtained under the control of taste. The picture is very well made up, especially in the arrangement of the figures, whose dark dresses have assisted the result, to which much merit is due.

W. J. Stillman (No. 130), *Temple of Concord, Sicily*.—This is one of several photographs by this well-known exhibitor, whose efforts towards making Grecian architecture familiar from the realistic point of view have here met with most signal success in this picture, which is an enlargement, but so rich in possible detail, that there would seem no limit to a much larger scale. It is in pictures of this class that photography stands out pre-eminent, and to this exhibitor, with his great experience in classic ground, much praise is due for bringing before those who cannot visit the originals such truthful, but at the same time, so artistic a representation of Grecian architecture.

Richard Keene (No. 161), *Old Moreton Hall*.—This is one out of five photographs of this remarkably picturesque building; but this particular exhibit is full of quaint detail, which has been exceedingly well managed for an effective result. It is in pictures of this class that photography, guided by skill and experience, does so much good in perpetuating bygone architectural romantic buildings.

W. Dillworth Howard (No. 172), *Italian Lake Views*.—Two small photographs, but possessing a distinct individuality. They appear to have been taken at early morn, or under a condition of slight mist, the result being two very charming pictorial bits, where photography shows that, by judicious treatment, a really picturesque result can be obtained.

Colonel W. L. Noverre (No. 180), *Ships, &c.*—On rough drawing paper. There are three studies in this frame of vessels, clouds, &c. The paper prepared by the exhibitor for photographic work is very

curious, inasmuch as, whilst showing an exceedingly coarse surface, it permits straight line to be given in all integrity. We hardly think the subjects chosen do full justice to the possibilities suggested, as a subject with more pronounced form might produce more effect. At the same time, if single lines can be rendered, it follows that any others must be good. Two of these photographs are pictures, and derive much value from the process, which at the moment is the exhibitor's own preparation.

THE APPARATUS.

To be so light and portable as it is, the $8\frac{1}{2} \times 6\frac{1}{2}$ "Gem" camera of Messrs. Sands & Hunter is very rigid. Its bellows body is conical in shape, and it has a variety of movements conducive to the comfort of amateurs, for which class it is constructed. This firm also exhibits another camera, the "Imperial," which is constructed mainly for tourists, having an unusually great range of focus. Either the back or the front can be placed at any part of the baseboard and firmly clamped there—no small advantage when one uses a lens of very short focus, the range of which would be interfered with by a projecting baseboard. Their well-known instantaneous shutter, so long associated with the firm, together with a threefold tripod stand and magnesium lamp, are also exhibited.

In the "Blair" camera, exhibited by Messrs. Fry & Co., an opportunity is afforded of examining the ingenuity and workmanship of American camera makers. The extension-piece of the transatlantic firm is a useful addition to a camera, as it forms an adapter, which converts any camera into one several sizes larger. It consists of a conical-shaped box, the smaller end of which fits into the camera like a dark slide, while the plate of increased dimensions finds accommodation in a slide in the larger end of the adapter.

The portable camera of Mr. William Scorer evinces ingenuity and careful workmanship. It has a circular front, fitted eccentrically, so as to bring the lens opposite any part of the plate.

To John Atkinson, of Liverpool, the founder of the present house of that name, belongs the honour of inventing a camera and plate box, which we rather imagine has been re-invented and patented by not a few since it was first invented and shown at a meeting of the London Photographic Society on January 8, 1857. It consisted of a grooved plate box, from which the plates could be passed in succession into the camera through an aperture, which was closed during exposure and reopened to allow of the plate being returned to the plate box, which was then slid along until the next plate in the series stood opposite the opening in the camera, when it in turn was made to pass in, either by dropping or, if of large dimensions, by being pushed. Perhaps the most elegant of all the cameras and reservoirs made on this principle was the little French Jumelle, which was constructed for military purposes, and held sixty plates, the mere act of applying the plate box to the camera effecting the opening of the shutters of both reservoir and camera by automatic action, and closing them by that of separation. Those specially interested in this class of instrument will find an article descriptive of it, with drawings and a record of experiments with it, in a former volume of this JOURNAL, that for 1869. The camera there described is still in our possession.

This same principle is applied in two cameras of foreign make now in the Exhibition, one of these being small and of the "hand" class, the other about half-plate size. They are exhibited by Mr. Oscar Scholzig. We are unable to name the maker, but the ingenuity of construction is undoubted.

The case of Messrs. Marion & Co. is not large, but it is replete with objects of novelty and utility. First of all, we may say that, not enclosed in the case, one of the graduated woollen backgrounds lately introduced by this firm, and spoken of at the time in these pages, is shown. There is a flat-folding dark-room lamp, which, judging by externals, seems as if it would prove a useful companion to a photographic tourist, who is often put to his wits' end as to how to discharge and recharge his plates from the dark slides. Samples of Developoids and packets of Eikonogen are also shown. Their "Perfect" camera is shown, fitted with one of Voigtlander's new wide-angle Euryscopes, a lens which we have already characterised as one which with a large aperture covers a wide field. Their other exhibits are a camera with repeating back, suitable for studio or field; a

camera case for making transparencies; Greenall's shutter, which opens and closes in the centre, and another new metal shutter.

Messrs. J. F. Shew & Co. exhibit "Eclipse" cameras in quarter and half-plate size; reducing and enlarging apparatus; flash lamp; and stands made in bamboo.

A specimen of Mr. S. D. McKellen's newly modified detector is shown. This style is now made in sizes up to whole plate. The detector gives either instantaneous or prolonged exposures, the conversion from the one condition to the other being easily effected.

URANIUM-GOLD PRINTING.

THE following is a description of an original method of printing from the negative that is at once simple, pleasing, and inexpensive. As it is by ferric agency that the "place is prepared" for the reception of the compound that forms the ultimate image, the process may reasonably be termed an "iron" one. The few details here presented take no claim to be considered exhaustive, and should rather be regarded as designed to elicit the ideas and attract the experiments of others.

The rationale of the process may be thus stated:—Suppose paper coated with ferric oxalate to be exposed to light behind a negative, there is formed a positive impression, chiefly in ferrous oxalate, which will easily reduce and be replaced by certain metallic compounds, as, for instance, gold and silver, and probably others. Thus we can obtain silver pictures by direct chemical substitution, as well as by printing out in the chloride or development. Among the important compounds that ferrous oxalate is powerless to reduce may be classed those of uranium. But if to a per-salt of this metal in solution there is added a small quantity of gold chloride, and the combined solution is washed over the ferrous picture, a ready deposition takes place. The gold, while being itself thrown down, carries the uranium with it, and becomes intimately united therewith to form the final positive image. The portions of the picture that were not affected by light have no reaction with the "developing" solution, and are thereby dissolved away, leaving only a surface of plain paper.

In the practical working of this method of printing the following are to be provided:—Paper coated with ferric oxalate, nitrate of uranium, chloride of gold, hydrochloric acid.

Iron per-oxalate is employed in several processes, but as the greater number of persons who handle it are ignorant of the facility with which it may be prepared, a convenient method of making a small quantity due to Pizzigubelli and Hubl is subjoined.

Dissolve two hundred grains of per-chloride of iron in four ounces of water, heat to boiling point and add hydrate of sodium, about one hundred grains will be required, until an alkaline reaction is indicated. Wash the precipitate with warm water, and when it is neutral to test paper, free it from nearly all the water by squeezing it in a clean piece of linen. The reddish-brown mass of ferric hydrate should now be placed in a flask, or other suitable vessel, about a hundred grains of oxalic acid added to it, and the vessel set aside in the dark for two or three days. The greenish-brown solution of ferric oxalate obtained at the end of that time should be filtered, and the amount of acid and iron therein contained determined by analysis. The solution should exhibit a decided acid reaction; if such is not the case a few crystals of oxalic acid are to be added. The solution is unstable, hence it is inadvisable to prepare more than sufficient for immediate needs.

The quantity of sensitive solution to be taken for coating the paper should be in the proportion of one grain of ferric oxalate to each square inch of surface. The sensitised paper will not deteriorate for several weeks if shielded from damp and light; if it is desired to preserve it for longer periods, the addition of a grain of mercuric chloride to each ounce of ferric solution before coating the paper is said to exercise a preservative effect.

When the dried iron paper has been exposed in contact with the negative and the characteristic ferrous image obtained, it should be floated upon a solution compounded in the following proportions:—

Nitrate of uranium	15 grains.
Chloride of gold	1 grain.
Water	1 ounce.

After the desired depth of deposition has been obtained the picture should be passed through plain water followed by immersion in dilute hydrochloric acid, 1:100, again treated with water, and finally allowed to dry.

The tone of the picture should be deep blue-black, and the image should not be deficient in vigour and balance. The proportions of the salts given above may be varied largely; the addition of more gold ensures a corresponding increase of the purplish element in the colour

of the print; its diminution tends to the predominance of the cold black of deposited uranium. The greater the quantity of gold taken, the more rapid will the reduction proceed. The appreciation of the points immediately enumerated will place in the hands of the experimentalist every power to modify the colour of the picture and to restrain or accelerate development.

As nitrate of uranium may be purchased at a lower rate than the silver salt, and the quantity of gold employed need not, on the whole, exceed the average taken for toning albumenated of silver prints, the comparative cost of the little process I have sketched could be ascertained without difficulty: I do not think it would exceed that of any silver process at present in favour.

THOMAS BEDDING.

COLOURED PHOTOGRAPHS.

XI.

IN our last paper having, I hope, advantageously conquered the blues, we started on the consideration of the purple pigments. These form a most beautiful set of colours remarkable alike for their richness and depth. Having treated purple madder to a sufficient extent, we will now follow on with purple lake, burnt carmine, Indian purple, violet carmine, and mauve. To continue:—

Purple Lake.—This colour may be considered nothing more or less than a species of crimson lake, but with a purple tinge, and all its properties, generally speaking, may be set down as similar to it. It is transparent, and possesses very considerable power and depth, and may be accounted a very useful colour for shadows. As regards durability we know crimson lake to be a very dangerous colour to employ, and, indeed, every effort should be made to avoid its use as much as possible, while much more cannot be said for purple lake; nevertheless, the latter has considerable advantage over the former on this score, still it would be reckless to secure any of the leading effects in a picture by the aid of such an unstable medium. I think with this we can dismiss purple lake, and pass on to—

Burnt Carmine.—As the name signifies, this pigment is obtained by partially charring or burning carmine; as a result, however, we have a very magnificent reddish purple possessed of extreme richness and depth. This process of charring the original carmine, although producing a very beautiful colour, does not seem to alter in the least its durability. We must, therefore, look upon carmine and burnt carmine as one and the same colour as regards permanency.

Indian Purple.—This pigment is in colour of a very deep tone—a rather cold and subdued purple. It is very much to be regretted that this colour shows a considerable tendency to blacken if submitted to the ordinary conditions of exposure. It is prepared by precipitating the colouring matter of a combination of cochineal on a base of oxide of copper.

Violet Carmine.—This pigment is a beautiful and brilliant bluish-purple, and possessed of more than ordinary richness of colour. It fades when exposed to light, and is apt to blacken. It is prepared from the root of the *Anchusa tinctoria*.

Mauve.—This colour is a lake prepared from aniline, and owing to its shiftiness should only be used for temporary purposes; indeed, it would be the extreme of folly for any water-colour painter to use it at all, so rapid is its disappearance. It is by far the most fugitive of all our modern water colours when submitted to the test of ordinary daylight; indeed, if you wish to remain in a state of confidence with those around you when you have this colour in your box you should keep the lid shut, if you don't you certainly will miss it. With this disreputable colour we have arrived at the end of our list of the purple pigments. The next series to claim our attention is the browns. No doubt you have met in life very worthy specimens of this somewhat large family.

Under this heading we will have to consider Rubens' madder, bistre, burnt amber, Cologne earth, warm sepia, and Roman sepia, these, with brown madder, Vandyke brown, and sepia (friends we have met before), complete the list.

Rubens' Madder.—As its name suggests, this colour, like brown madder, is a preparation of the madder root. It is much brighter in tone and more russet in hue than brown madder. Like all the colours having a madder base, it may be considered practically permanent under the ordinary conditions of illumination, exposure to ordinary diffused daylight having virtually no effect upon it. In short, its various properties are much the same as we know brown madders to be.

Bistre.—This colour is a powerful citrine-brown, and is possessed of much clearness; it is very useful in treating architectural subjects on this account. Under the ordinary conditions of exposure it may be considered durable but not absolutely permanent. As I say, under

ordinary conditions it is all right, but it must be confessed that exposure to bright sunlight will cause it to fade very considerably. It is prepared from the soot of wood fires.

Burnt Umber.—This colour is produced by calcining raw umber; the raw earth having undergone this treatment becomes much deeper in tone as well as more russet in hue. Burnt umber will be found to wash well and work easily. To these latter good qualities, also, may be added one more, though "last not least," under all conditions of rational exposure it is eminently durable.

Cologne Earth.—This colour, as originally made, was a native bituminous earth, but latterly this pigment has been produced by calcining Vandyke brown. This method of producing Cologne earth has its advantages, and among others, quite apart from the fact of its very close resemblance to the old Cologne earth, includes the quality of greater durability.

Warm Sepia.—This pigment may be looked upon as a mixture. Sepia—the ordinary colour bearing that name—is a powerful dusky brown, possessing extremely fine texture, and when warmed, by mixing with it browns of a reddish hue, becomes what is known as warm sepia. If kept from a very strong light it is practically durable, but exposure to strong sunshine will cause it to fade very considerably. It is transparent, works and washes well, and is extremely clear in its pale washes.

Roman Sepia.—This pigment, like warm sepia, is also a mixture, but instead of having an ingredient of a reddish hue, has one of a yellow tendency. From this point it closely resembles the other sepias in all their leading qualities.

With this we may safely conclude that we have treated on all the various colours to be found included under the heading of the Brown Pigments. The next set will be the *citrine* and *olive* pigments. Among these will be found brown pink, raw umber, and olive green.

Brown Pink.—This pigment was originally a lake prepared from Persian berries, but was not very remarkable for its durability. As this quality is so essential, it is only natural to suppose that efforts should be made from time to time to better the various suspected products at our command. In this manner the latter-day brown pink is a product of quercitron bark, and one which possesses considerably more stability than the old colour did. I do not wish it to be understood that this says very much for it, all the same as in truth its reputation must be set down as very varying. This is naturally influenced to a very considerable extent by its composition and manufacture, as well as by the severity of the test of exposure to light to which it may be subjected.

Brown pink is a very fine citrine colour, possessing considerable richness and transparency, and also works well with the brush. Under the direct rays of the sun, I may here state, both these varieties are unquestionably fugitive, and this remark applies with greater force to the product prepared from the Persian berries than that which is produced from the quercitron bark. It is needless to say that exposure to the fierce rays of the sun is not a likely one to which pictures of merit, not to say works of art, would be submitted. It would only be courting destruction to treat them thus. I may, therefore, state that there has been considerable evidence from time to time to prove that both varieties of this colour are to an extent durable when only exposed to a judiciously moderated daylight.

Raw Umber.—This pigment is produced from a natural earth or ochre, deriving its colour from the presence of the hydrated oxides of iron and manganese. The finest specimens of this colour come from Cyprus, and are often styled "Turkish" or "Levant Umber."

Raw umber is possessed of a very fine brownish citrine colour, and has a tendency somewhat to darken as time rolls on, and is semi-opaque. If measured by ordinary conditions it may be considered durable, but if unduly exposed to the fierce rays of direct sunlight it has been found, after lengthened exposure, to fade slightly.

Olive Green.—This colour, sometimes known as *Devant's Green*, is a mixed pigment, and is possessed of a fine deep olive colour and sober richness. As is the case with all compound pigments, the degree of permanency of the individual colour may be approximated by duly considering the claims upon durability held by the original colours, whose combination produces the olive green under notice. As a general rule, I think it will be found that this colour, like many others, leans more to the advantage of being beautiful than the virtue of being permanent. Although there is no denying that strong sunlight will have an undoubted effect on and destroy much of the beauty of this erratic colour, there is strong reason to believe that under moderate and careful conditions, namely, exposure to ordinary *daylight*, at least some of the many varieties stand fairly well.

With this we conclude the citrine or olive series, and make our final advance upon the last few colours that form the grey and black pigments. When we have given these few remaining colours their

due consideration, we will have completed a more or less exhaustive inquiry into the qualities of nearly all the pigments to be found in a water-colour painter's box. The colours forming the series which we may term grey pigments are few, only three in number, viz., ultramarine ash, neutral tint, and Payne's grey.

Ultramarine Ash.—This pigment is a valuable pale azure-grey colour, variable somewhat in its degrees of intensity, but as regards its permanence ever the same. It is a very useful colour in obtaining several of the most delicate atmospheric effects. It is prepared from the *lapis lazuli* after the richer blue has been extracted.

Neutral Tint.—This is a compound (if I may be allowed to say) shadow colour, being of a cool neutral tone. It cannot be considered as permanent, as exposure will considerably weaken it. A means, however, of preventing this is to mix a small quantity of ultramarine ash with it. This simple addition will add considerably to the durability of this otherwise very useful colour.

Payne's Grey.—This is a very similar compound colour to neutral tint. On close observation this pigment will be found to be more lilac in hue, but in all other qualities and properties it entirely resembles neutral tint. With this our grey series ends, and we will at once hasten to finish our analysis of the colours by considering the black pigments. Under this heading will be found, ivory black, lamp black, and blue black.

Ivory Black.—This pigment is the richest and most transparent black we possess, and when properly made is extremely durable. In its paler washes it will be found to possess a somewhat brownish hue. It is produced by charring ivory, as may be supposed from the name.

Lamp Black.—This pigment is a most useful colour. It is a black of very fine texture and great power. It is scarcely so transparent as ivory black, nor is it quite so intense, but it has the advantage of not being so brown in its paler washes. Owing to the natural power of this colour, it should be used with caution, its inherent density, if injudiciously used, is more than likely to give a general feeling of heaviness to our picture. It is prepared from the soot of burning resinous matter.

Blue Black.—As a black this is perhaps the most useful to the landscape painter. It is possessed of less density than either ivory black or lamp black, and is naturally less likely than either to give a sooty effect where such would be most undesirable. It is prepared by calcining vine twigs.

At last we have come to the end of our analysis, and I have no doubt you will say that you are "very glad," and "it is quite time," and such-like. I beg to say, however, that no one of my readers will be more pleased than your humble servant. It is a horrid task to go all through such a long list with little of interest to lend it a charm. I feel sure, however, that in the main it is worth the trouble. It has cleared away all the obstacles before us, and we can now attack our work, feeling sure we know something of the means we are using to gain a fixed result. All of this may not appear necessary for "mere photographic colouring," but my object is to show that really first-rate work can be produced on photographic base, and how to do it. As I have often said (and this will prove before it is finished), photography can be a great help to the *real artist*, but to the *incompetent* one it is a most exacting task master.

REDMOND BARNETT.

THE WHOLE DUTY OF THE PHOTOGRAPHER.

III.

"Fools rush in where angels fear to tread."

THIS is a true proverb, and I am about to exemplify its truth by rushing on to that dreadful battle field called art criticism. On this grim field there is one little corner especially reserved for those who have dealt with photography. The space is small, but the fight was hot and many have fallen; poor little pigmies most of them, who have shattered themselves in vain against the rocks of ignorance, folly, and prejudice. It must be confessed that the aspect of the victims on this ground moves one rather to laughter than to tears. To come down from this stilted rhetoric and write plain English, I am about to venture to speak of "art in photography," and I reckon that there are few departments of literature where folly has so long reigned supreme, and in which deeper misconceptions of truth have prevailed.

As I have said before, all men are artists in so far as they endeavour in their lives to surpass the purely animal existence. The majority in this country are what we may call negative artists, and devote their energies to the development of ugliness and the final destruction of all sense of beauty. Of such are School Boards, Science and Art Departments, and well-nigh all the mechanism of education, both higher and lower. Would a man acquire a feeling for what is

beautiful and seek to make his environment a fit habitation for a rational creature? He must learn not only outside the schools, but in direct opposition to what is taught there.

The term "art in photography" is a false one; it should rather be the position of the photographer in relation to art, for the less does not include the greater.

In the greatest of all temples, where are performed the rites of the worship of beauty, the photographer has a place among the celebrants, and although not the first, neither is it the last nor without value. The question which I wish to answer to the best of my ability is, What is the nature of the function assigned to photography in the temple, where is its niche, and how is it filled? The first place must for ever be reserved for the artist in the narrower acceptance of the term, not the narrowest, however, for by artist I do not mean only the person who makes pictures or statues, but include also those who design rooms and buildings, or gardens or towns. Why all these should be classed as mere craftsmen under the name of decorators, builders, gardeners, &c., is a question I have never been able to fathom.

The photographer's function, we must confess, is that narrower one of making pictures, and even within that there are many restrictions. "Know thyself" includes all human wisdom, and applies to small as to great, and not less here than elsewhere. Let the photographer know what he can do and *what he cannot*. The latter I should call even more important than the former; let him study his limitations and submit to the laws of the higher powers. The first and greatest limitation is colour; the compulsion to render in monochrome not only loses the colour itself, but destroys also most of the finer and subtler detail of light and shade. Nothing in the world is more wonderful or more beautiful to the eye that can see it than the deep glow of sombre colour in a dark shadow. Will photography ever render this? That we shall learn to reproduce colour in some fashion I do not doubt, though the triumph seems still far off; but it seems too much to hope that all the marvels of subtle colouring of a sunlit landscape can be rendered without the agency of what we call the genius of the artist. Looking into the shadows of pictures which appear at first sight mere blots of darkness, one may often distinguish the most astonishing mixture of rich colours—red, green, blue, and purple in wonderful combination. Let not the photographer altogether despair of one day doing justice even to such shadows as these, for there are two cases—either the colours are veritably there in nature, in which case they may be copied, or they are not there, and the artist's representation is purely conventional, as happens often enough. In this case it may be reserved for the photographer to teach the artist, as he has done once or twice already.

The second great limitation to which photographers have to submit lies in the impartiality of the lens, which stupidly insists on representing whatever is in front of it, so that an otherwise perfect picture may be ruined by the branch of a tree or some obtrusive bit of wall. Some photographers there are who yield to the temptation, very strong under such circumstances, to improve nature with an axe: of this, perhaps, the less we say the better.

It is very amusing and not a little instructive to hear artists discussing the pictures they have in view: "Yes, that would make a picture if you put in some foreground;" or, "That hillside is too low, I must put some trees on it;" or, again, "I am going to put a cottage and a cart of peats into that hollow;" thus improving the surface of the earth with a most lavish hand. This is right, too, for one of the greatest of all the follies uttered under the name of art criticism is the dogma that the function of the artist is to represent exactly what he sees. On the contrary, his duty is to make our environment beautiful, and one of the ways in which he does this is by the making of pictures. The inquiry whether the picture is accurate is entirely irrelevant; let the maker of maps and diagrams attend to his own business. It is true that the artist does always represent things which are, or have been, in the world, but he combines and groups them to please himself. Consider a sufficiently familiar instance—a scene being enacted before me while I write. A woman is driving a herd of cows to milking, not without a free use of stick, stones, and profanity. The scene is in its way a beautiful one, well worthy of any artist; how may it be represented? A photographer, with all his paraphernalia of rapid lens, quick plates, and shutter might wait a lifetime before he could get the cows and their driver properly grouped so as to make a picture. The painter has no such trouble. After studying the scene several times he should have learnt by heart the attitudes and grouping natural to both herd and driver, and then he can transfer them to canvas. It may happen that exactly what he represents never was to be seen; still, his picture gives a truer and deeper idea of the whole than a representation, however accurate, of the scene at any one moment. The artist has

idealised, has shown, in truth, more than the ordinary eye could discover, and therein lies his highest purpose—that of idealising life and interpreting for less fortunate men the higher levels of beauty. The photographer must for ever remain one of the crowd, reverently admiring this higher land to which he can never attain, for he must represent what he sees at any moment, though I consider all the devices of double printing, and composites, and cloud negatives, perfectly warrantable, and in judicious hands valuable. These are, at the least, only partial remedies for the want of the power to eliminate, and each mechanical aid of this sort brings with it in its train a new collection of technical errors of application to be added to the already numerous artistic errors natural to the imperfect man.

So much, then, for what photography cannot do; now to indicate some of its peculiar powers, and in what directions it may legitimately claim to rank as a fine art. Clearly in the accurate representation of form and detail the photographer is easily first. He should then devote his attention, as much as possible, to depicting objects which depend chiefly on their shape, or outline, or fineness of detail, for their beauty. In the representation of light and shade, although he is at a disadvantage, he is not to be despised; and, lastly, the quickness of his operations may enable him to seize on many fleeting effects too transient for either brush or pencil.

The most beautiful photographs I ever saw were of bare trees covered with ice crystals; but leafless trees at any time are a perfect subject, and one to be had, too, in winter, when times are bad and sitters few and far between. Winter also is the season at which trees will stand for their portraits. When they are in the pride of their summer garment a group of a dozen babies is not so restless as a tree. Time after time I have watched the leaves for ten minutes or longer and detected no movement. Exclaiming, "Now is the time!" I went for a camera, but before I got it planted a gale had arisen, and the trees did not mean to be still again for a month. Such events are trials, and the photographer is far from patient under them. He seems to think that because his exposures take only a few seconds, therefore he ought to be able to make pictures at the rate of one every few minutes. There could not be a greater mistake. Let him consider the ways of the artist and be wise. We do not see artists endeavouring to produce a picture every hour of the day, or every day in the year; on the contrary, they usually spend many days in pottering about looking at points of view, and sometimes making little sketches to see how things will look in a picture before bringing out a large canvas and beginning to work on it. If the artist produces in a fortnight or so one picture which is really a thing of beauty he rejoices. Much more, then, the photographer with his severer limitations if in a similar time he can produce one photograph really worthy to be called a picture. Of course, on the way to this result he must have many failures, and I would urge upon him to destroy freely. Do not let bad or indifferent work go out into the world to degrade the name of the art. Keep a high ideal in view from the beginning, and march towards it courageously through paths strewn with broken glass.

COSMO. I. BURTON.

ELECTRIC LIGHT LANTERNS.

WITH the introduction of the house to house supply of electricity in London, and other large cities and towns, the use of the electric light will no doubt be considerably extended, not only for general illumination, but also for special purposes, such as projection work, enlargements, &c.

Previously, as far as the optical lantern was concerned, very few—outside large institutions, such as the Royal Institution, the Society of Arts, and some of the universities and colleges—could use this light, for to get a satisfactory result it meant a great outlay for plant, consisting, in the case of one of the institutions named, of a gas engine, dynamo, secondary batteries (to ensure steady supply), and the lamps, in all about 700*l*. Now the whole thing is altered, and any private individual or school can utilise the current at a nominal cost. Central burning arc lights can be obtained to give 1000 candle power for special purposes, such as using high-power projection microscopes, micro-polariscope, &c.; but at the present moment I propose dealing with the incandescent form of lamp, which is easy to use, and will give satisfactory results for moderate-sized rooms. All who have seen the ordinary incandescent electric light lamp will remember the illuminating filament is elongated and covers a large area—a factor the very reverse of what is required for illuminating an optical system. The light should be approaching that of a point in order to get satisfactory definition and illumination, an area of light of half an inch or so diameter being suitable. With large area of light the rays pass through the lenses from so many points that they come to a focus

at other places than the axis of the optical system, and therefore give indifferent illumination or definition. In order to meet the wants of scientific men and the large number of people who use optical instruments, Professor Fleming, of University College, London, designed a filament that gives all the light in a suitable circumscribed area, and at the same time a brilliant and satisfactory luminant of 50 or even 100 candle-power. It is done by crumpling up the filament in a grid-iron form, so that while the necessary length is obtained to get a long line of luminosity, it is at the same time all concentrated. This is known as the "Focus" lamp.

I had occasion to experiment with one when asked by a captain of a mail vessel if an electric light could be fitted to his enlarging lantern, so that he could use it on board ship for the amusement of his friends or the passengers. The globe of glass (exhausted of air) which contains the filament is about three and half inches diameter, and this was found to be most readily adapted by mounting it in a brass gibbet-shaped arm or rod, the end of which fitted in a stand attached to the ordinary lantern tray. A circular hole in the stand with a clamp allowed of the vertical or lateral adjustment of the lamp, and so the light was readily got central. On connecting it up to a local electric light installation (one of the best in London), it was found to give a satisfactory disc up to ten or twelve feet. Certain points of improvement suggested themselves for a lantern with which to use this light, and Dr. Fleming, to whom the report was made, designed, and instructed Mr. J. H. Steward, of 406, Strand, to make a lantern that should enable photographic and other slides to be shown conveniently, and, at the same time, permit of numerous scientific projections to be made, illustrative of magnetism, electricity, fluids, &c., for it can be either used horizontally or vertically, the front lens, of large diameter and medium focus, having an adjustable mirror that will reflect the rays in the desired direction. In form it is an oblong box with three sides closed, with the exception of ventilating holes and any special door or opening that may be required; and the fourth side composed of hinged doors opening in sections, so that any part of the apparatus can be readily got at. Grooves are placed down the inside, and into these are slid the mounts containing respectively the stage, condenser, &c. The lamp is mounted on a moving base worked by rack and pinion from outside, and the objective is fastened by a brass flange to one end of the mahogany body. Every possible adjustment can thus be obtained, and by means of the various grooves any distance from the lens can be arranged for. The objective slides out of the rack front complete, so that another focus objective can be used quickly if desired. Levelling screws are supplied for both vertical and horizontal work, so that delicate experiments with the galvanometer, &c., can be performed. While the focus lamp can be used in any large-size lantern body, it is better to have one specially made, so that the necessary arrangements for ventilation may be allowed for, the heat generated by the lamp requiring special facilities for the ready change of hot for cool air inside the lantern.

Although, in my opinion, the light will never supersede the lime-light for lantern illumination where compressed gas can be obtained, it supplies a want, and will be a great convenience to many for trying slides, enlarging purposes, and for lecture demonstrations on a scale sufficient to suit an audience of one hundred or two hundred persons. One of these lanterns was shown at the last *soirée* of the Royal Society, and considerable interest was taken in it, as well as in other electrical exhibits of a scientific nature by Dr. Fleming.

G. R. BAKER.

PHOTOGRAPHS, PLAIN OR COLOURED.

By rights, the title of this paper should be *Coloured Photographs*, but as a series of articles are appearing weekly under this title, I will vary it a little for distinction sake. I do not suppose, since photography became popular, there has been a more debated question than this of coloured photographs, or one that has branched off into so many side issues, starting with the legitimacy of calling a photograph a photograph when it has been subjected to the manipulations of the colourist or hand work generally. At one time, if hand work could be detected on a photograph, even if it required the aid of a magnifier, it was disqualified as unfit to compete with its untouched brotherhood. Then, again, pictures were admitted for competition with others if a great part of their *artistic* beauty depended on hand work, so long as it was skilfully hidden.

Now the question arises, What is a coloured photograph? It will scarcely do to say in reply, off-hand, that it is one that has received a certain amount of artist's work in addition to the chemical and undoubtedly legitimate work of the light itself, because this would at once land us in a difficulty, for without doubt the majority of nega-

tives can be vastly improved by it, and I cannot see why any distinction should be drawn between this and colour applied at some other stage. Coloured work, although it may be in monochrome, if applied to the negative or to the resultant prints is a mere matter of degree. When all is said, the photograph will owe some of its beauty to something independent of the effects of light. A negative so doctored will produce a print that will enter unchallenged into almost any competition, whereas if a fraction of the amount of work is put on the print its doom is sealed. A clever draughtsman could make a negative almost entirely by hand work, innocent alike of camera or lens—pinhole or otherwise—that would pass muster as an ordinary negative, and a copy from it might claim to be an untouched photograph simply because the positive copy had escaped the damning (*sic*) touch of brush or pencil. It is all very well to say that it is perfectly understood what a coloured photograph is, but this is just the point of which, in my opinion, there is considerable doubt; if it is right to exclude work improved by brush or pencil in one stage, I cannot see why it should not in another. Take the choicest work of any good photographer, and it will be found that the negatives, at any rate, have been pencilled or papered, or rubbed down or strengthened up, or something or other that the light had no part in the effecting this in landscape work. In portraiture it is infinitely worse. The original is so worked on, that if the camera was a sentient thing it would not know its own offspring. The retoucher, if he has an eye for the beautiful, more or less idealises the, may be, commonplace figures he has to work on; and the more he idealises without actually losing the likeness, the more is his work appreciated. Purists may hold up their hands in horror, but it is a fact all the same, and a portrait not worked on and smoothed up is considered coarse and unfinished. Merely touching out defects or softening exaggerated lines is not sufficient, although it is somewhat difficult to say where the line is to be drawn and as to how much shall be done or left undone. That very elastic phrase, "Only just sufficient," depends on who does it and who says it, and may either mean a tremendous lot of work or very little indeed, according to circumstances.

Now, again, when we begin to argue about truthfulness, we see a coarse, wrinkled, spotty epidermis "made up" with powder and *cosmetiques* into a blooming childhood quality for the special behoof of the photographer; retouching is done on the *subject* here, and possibly does away, in a great degree, with the necessity for it on the negative; but it is just as misleading, as we do not get a true representation of the original as generally understood, the colour being applied at the beginning instead of the end of the process. Very few have that Cromwellian force of character to prefer the warts, and I think, for the sake of the community at large, it is a very good thing they don't. We have only to go through an old album of portraits, or, I should rather say, an album of old portraits, side by side with one of modern good work, and then decide which style we prefer, even as bare remembrances of the personal appearance of our friends.

People we like we involuntarily idealise in our own minds, and prefer the refined, if incorrect manner of representing them, apart from any idea of exaggerated improvement; in fact, it is very seldom, to speak broadly, that we notice *slight* defects or imperfections in those with whom we associate. How many, for instance, could, without hesitation, say what was the colour of the eyes of a friend (unless of a particularly intimate one) from recollection, or unless they were particularly striking eyes? This actual ignorance of facts and defects has much to do with the popularity of retouching; they are unnoticed in the person, and probably only brought into notice by the close criticism usually bestowed on photographs. Most people can call to mind a remark of this character: "Dear me, your nose is all on one side!" or, "One eye is larger than the other!" or, "The mouth is wrong!" or some flattering speech or other that may be perfectly truthful; but the defect is not realised until the photographer has done his work. If by any brush or pencil skill faults are made less noticeable, it, in my opinion, is better for everybody. It is very true that retouching may be carried to such excess that it becomes positively hideous—all the natural texture of the skin done away with, and the photograph, instead of looking like a copy of a human being, looks more like one of a wax doll or a marble bust; it neither adds beauty or conveys a pleasing impression; it does not have the effect of idealising, but destroys any beauty that may exist: and here I think we must draw the line as to retouching or colouring the negative.

We now advance a stage, to the print, for with every care bestowed on the negative a little retouching on the prints for the reduction of the intensity of too strong lights, and the removal of some altogether, greatly increases the artistic qualities of the picture. A mass of shadow broken up by small brilliant spots of light generally gives an unpleasant effect, and necessitates the use of colour for their removal. The untouched picture looks crude and unsatisfactory compared with

a print that has undergone this colouring, or call it by some other name—spotting, if preferred—the result is the same; the effect of the picture is due to hand work, and not to pure photography. I am quite aware that when coloured work is talked of, photographs upon which many varied colours have been applied is usually indicated, or photographs on which the photograph is absolutely invisible; it is a mere matter of degree (and, perhaps, the first indication of the existence of a photographic base is its fading or discolouration). In such cases would it not be better to drop the word photograph entirely, the photograph being as practically hidden as is the charcoal sketch of the painter? in fact, it in many cases only serves the same purposes, and disappears as the colour is laid on. It is quite misleading to call such a production a coloured photograph; although custom has accepted the definition, the sooner the same authority discards it the better.

So much, then, for what a coloured photograph should not be; as to what it should be is, I take it, another matter, and may be fairly described as a photograph in which the chemical image is *not* hidden by applied colour, but is in evidence throughout the work. In such cases there could be no doubt as to the existence of the photograph, but as to whether it was improved by the colouring is another matter—tastes differ; but I think any picture exceptionally good passing under the title of a coloured photograph will be found to show no evidence of the photograph itself, but merely of the work that has been put on it.

EDWARD DUNMORE.

LANDSCAPE ART.

It is rather in the nature of a compliment, at least I feel it so, that the rather irate "F.B.," on page 674 of this JOURNAL, takes exception to a casual expression of mine on this subject, as it shows that the remarks have been read carefully, if not appreciatively.

That expression, which after all is only one of opinion, is, "But it is perfectly patent to all who choose to look that it (photography) has quite revolutionised the landscape art, not only of this country, but of Europe, with perhaps the single exception of Holland and the Low Countries"—a sufficiently wide assertion. And as he puts his view in the form of a question, "It would be interesting, indeed, to learn in what way the landscape art is for a single instant revolutionised by photography?" the question might be very fairly and shortly answered in the Scotch fashion by asking another.

Where was the landscape art of Europe before its advent? Should we look for it in Italy, which must be looked upon as the birth home of modern art? and how many landscape artists has the modern Italy produced? Is landscape art to be found in the works of, say, Salvator Rosa, with his magnificent dreams of impossible mountains, gorges, and trees; the passes inhabited by goats and picturesque brigands drawn with great power and vigour, and dashed off with what appears to be the skill and rapidity of the scene painter? or are we to take the truths of nature which photography teaches from the landscapes and cattle of Rosa da Tivoli, whose works may be taken as coarse sketches of sheep and cattle with the landscape thrown in as a make-weight? The landscape backgrounds of such of the great Italian masters as I have seen are, while beautifully painted, utterly untrue to nature, whether we take them from Titian or from Raffaele, from the Bellini or Domenichino or Tintoretto, and they are invariably subordinate to the rest of the subject, which may be, and no doubt is, right enough; but they are purely from the artist's imagination, and put there merely to help the composition either by its form or its colour, and rarely even for its suggestiveness, to say nothing of the truth to nature. Among the more modern men, Canaletto and Guardi, with their almost photographically correct architectural views of Venetian subjects, may be quoted as about the only exceptions in Italian landscape art, for even the comparatively modern Swaneveldt is no true landscape artist; but since the advent of photography, Italy is beginning to have a taste for, and is creating a school of, landscape art.

Where can we find in Spanish art anything of the truth of this art of landscape? Velasquez, Ribera, Murillo, Zurbaran, were all great artists, but they, together with all the long catalogue of names and work which Sir William Stirling Maxwell, the greatest authority on the subject, in his two volumes, treat landscape as if of no account in picture making. Indeed, it would seem that before the advent of photography no one ever thought of reproducing landscape in art; but now we have Spaniards whose work will compare favourably and take rank with any of their contemporaries.

Germany, in its early artistic stages, with Albert Dürer as the greatest of its exponents, while great as an artist, admirable in draughtmanship, and almost unique in conception, shows the same want of feeling for this department of art. A beautifully drawn

flower, a few pebbles, or a tuft of grass in the foreground, with the slightest indication of the distant landscape, are abundantly often there to show, not want of capability, but rather the absence of appreciation or contempt for those beauties of nature of which his skill could so lovingly represent when he chose or it suited his purpose; for Dürer was a man who made his art subservient to his high imaginative power. I cannot call to recollection any school of German landscape art which is not of the very modern type, and doubtfully good at that.

The art of the Northern nations—Russia and the Scandinavian countries—is, like our own, the creation of a much more modern period indeed, but the creation of this century, and so within the memory of the generation of still living men; and coming to that of France, with probably the exceptions of Joseph Vernet and Claude Lorraine, all the historic painters have gone for what is (I think) erroneously called high art, and it may be added as typical of the nation of interminable miles of battle pieces. Vernet's pictures are, in many instances, beautiful works of the painter's art; but, like those of Claude, he subordinated nature to the imagination of the artist, and in the desire to improve the unimprovable they created grand conceptions and effects which never existed, save on their own canvases.

It does seem to me that the primary consideration of the landscapist should be to represent as truly as may be, with the limited means at his command, the varied scenes of those aspects of nature which affect his peculiar susceptibilities, and through this to excite the same or similar feelings in those who see and enjoy his work. I also hold it may be wrong that the painters of the, to us, rather unpicturesque countries of Holland and Flanders (speaking generally) tried to do this, and succeeded better than those of any other of the art-practising countries, and that none came nearer to that truth than such men (among many others) as Albert Cuyp, Ruysdael, Hobbima, and David Teniers; and if the landscape art of this country has been indebted to any, it is to the influence of such men.

In this country our artistic susceptibilities were later, in point of time, of being evoked, and our painters very probably from their surroundings, both physical and literary, seem to have taken more appreciatively to the representations of the sea-girt isles with their many beauties than to the high art of the Continent. This they did at first crudely enough; but it must be admitted, even by "F.B.," that in this department have been the greatest triumphs.

What does Dr. Wolcott—"Peter Pindar"—say in criticising the exhibitions of the first years of the Royal Academy of London? to so great a man as Gainsborough he gives this advice:—

"To mind his landscape, have the modest grace
To see there sometimes nature's tints despised,
I wish them more attended to and prized."

And of another, and the principal landscape painter of the period:—

"And Louthborough, whom heaven so wills
To make brass skies, and golden hills
With marble bullocks, in glass pastures grazing,
Thy reputation, too, will rise,
And people, gaping with surprise,
Cry, Monsieur Louthborough is most amazing!"

But without going into the history of English landscape art and coming to our more immediate times, one remark may settle the matter. Did not Turner see the inherent untruth of the landscape art of Claude, and to prove his views produced the famous *Liber Veritatis* in rivalry to the *Liber Studiorum*? and yet, with all the beauty and attempted truth of the *Veritatis*, we see through the education which photography has so widely spread and insensibly given to every student and every individual, that Turner fails almost as much as does Claude. This is where photography is teaching, if it has not taught, how to represent truly instead of untruly. If this is not revolution it is perilously near it.

And coming down almost to the present date, allow a quotation from the editorial columns of this JOURNAL, page 288, of 1886:—

"The Royal Academy Exhibition is now open. Although the Exhibition may be said to be below the average of previous years, there are many pictures which should be studied by photographers. Several of the pictures, both portrait and landscape, bear strong evidence of having been painted, wholly or partly, from photographs. Many painters, although they profess a contempt for it, are largely indebted to photography for many of their pictures. Others, on the contrary, make no secret of it that they employ photographs to assist them in their work. Indeed, several well-known landscape painters now possess a photographic outfit and profit by its employment, and, what is more, they are not ashamed to own it. The more credit to them."

The second count of the indictment is, that I have in the same article further stated that "several of the most famous names in art circles are not content with either copying early (?) (*i.e.*, I might

have said their own earlier designed works) "but carefully drawn designs by the use of our art, but go much further than that, and get the same reproduced on the canvas or the panel prepared for painting." "I deny," he says, "the truthfulness of the assertion that an artist exists," &c.

But still, denial notwithstanding, the statement is one of actual fact and literal truth. Two, at least, of different pictures by one of the first rank of living artists, produced in the way described, were sold by me for upwards of 300*l.* a-piece: one of these was to a gentleman reputed to be one of the best judges in London, and I know he has a fine collection, having seen it; the other was sold here for a similar sum, and to an equally capable judge.

These are not the only instances of living artists, they could be multiplied quite easily were it either expedient or desirable; but it will be easily understood that with living persons it is not wise to use names or dignities.

In the case of deceased artists it is different, and as both parties in the case to be quoted are now dead no harm can accrue. The late Mr. —, of the Montreal *Herald* or *Gazette*, was a lover of the fine arts, and used to come over to this country once a-year on a holiday, and he generally bought a picture or two. On one of these occasions he, instead of buying what might be on sale, left commissions for at least half a dozen of pictures in oil. Two of these were to be from the brush of the late Samuel Bough, R.S.A., one of the best landscape painters, English or Scotch, then living. The subjects selected had been previously executed, and were engraved also, of a small size; the subjects of both were landscapes and figures. The price was to be, writing from recollection, 120*l.* a-piece. The artist grumbled very much over the price, but as they were to be used for an exhibition on the other side he agreed, swearing he'd be — before he'd be at the trouble of drawing them at the price, so he employed me to photograph and print them on canvas. The size was about thirty-six inches on the base line, and as at the time I had no bath of the size necessary, they were made with bromide emulsion from transparencies, using the lantern and the limelight. If I recollect—well, the exposure was about a quarter of an hour. The result was perfectly good, and the printed canvases were delivered within a few days.

This, I think, should satisfy "F.B." of the facts; and all who know Mr. Bough know the contemptatory fun he used constantly to poke at photographers and photography in public and private. I hardly expected at this time of day to have my veracity called in question. Opinion and judgment are very different. W. H. DAVIES.

A PHOTOGRAPHIC BLUE-BOOK.

BLUE-BOOKS are so intimately associated with matters parliamentary, that it would seem at first sight almost an anomaly to speak of a Blue-book as in any way connected with photography. While the Blue-book of our legislators is in all sincerity plentiful enough, copies of the work which form the subject of the present communication are rarely to be met with. We presume the regulation Blue-book takes its title from its outside covering; but here the reverse holds good, the contents themselves forming a series of blue impressions.

Book collecting is more or less a disease, and a somewhat incurable one. Book hunting, as a famous namesake of my own, Mr. Andrew Lang, refers to it, is a genuine sport. The two things are by no means synonymous. Book collecting is one thing, and it may be extensively and expensively indulged in without any of the sport to be obtained when a veritable hunt for a coveted and scarce volume is entered upon. The volumes we are here dealing with are the results of a hunt which has been pursued for several years; in fact, continued so long as almost to doubt the possibility that the quarry would ever be successfully "run to earth." In an article on *Photography without the use of Silver*, which appeared in the *THE BRITISH JOURNAL OF PHOTOGRAPHY*, December 9, 1864, and contributed by the illustrious Henry Fox Talbot, we find the writer saying:—"We know that some photographic processes are permanent; for instance, the cyanotype of Sir John Herschel, by which process a lady some years ago photographed an entire series of British seaweeds, and most kindly and liberally distributed the copies to persons interested in botany and photography. The whole of these prints remain unaltered after the lapse of several years."

It was these observations of Talbot's which first brought the existence of such a work before my notice, and although it is many years ago since they were written, I had never been able to come across any photographic friend who had either heard of or seen the book. It seems, however, that the late Mr. Robert Hunt had possessed the work (whether he had received it direct from the author or how he had acquired it I have no means of knowing), but be that as it may, it

is sufficient for our purpose to state that the volumes we now possess are from the library of Mr. Hunt, and were bought last spring by a London dealer, from whom I acquired them. The fact that they have been at one time in the possession of Mr. Hunt adds a further element of interest. Whether we regard the work from a photographic or from a natural history point of view, the volumes are certainly unique in character. Our interest in these "Cyanotype impressions" is, as can be readily understood, mainly photographic. The two volumes may be described as large quarto, are neatly bound in half calf, and bear on the outside the title, *British Algae*.

Opening the first volume we find the initial page has the title, *British Algae*, Vol. I., printed in white on a blue ground, obviously the lettering had in the first instance been printed on a white sheet of paper with ordinary ink and then used as the negative. The following page has the inscription, "Photographs of British Algae—cyanotype impressions." The third page explains the purport of the work, and is evidently in the handwriting of the producer. We give it *in extenso*.

"The difficulty of making accurate drawings of objects so minute as many of the *Algae* and *Conferve*, has induced me to avail myself of Sir John Herschel's beautiful process of cyanotype to obtain impressions of the plants themselves, which I have much pleasure in offering to my botanical friends.

"I hope that, in general, the impressions will be found sharp and well-defined, but in some instances (such as the *Fuci*) the thickness of the specimens renders it impossible to press the glass used in taking photographs sufficiently close to them to ensure a perfect representation of every part; being, however, unwilling to omit any species to which I had access, I have preferred giving such impressions as I could obtain of these thick objects to their entire omission. I take this opportunity of returning my thanks to the friends who have allowed me to use their collections of *Algae* on this occasion.

"The names refer to Hervey's *Manual of British Algae*. I have taken the tribes and species in their proper order when I was able to do so, but in many cases I have been compelled to make long gaps from the want of the plants that should have been next inserted, and in this first number I have intentionally departed from the systematic arrangement, that I might give specimens of very various characters as a sample. A. A."

The fourth page takes the form of a dedication:—"To my dearest father this attempt is affectionately inscribed."

Then follow 190 plates of the various specimens reproduced, each one having its botanical name affixed.

The second volume contains 107 plates, to which there falls to be added 80, which have apparently been put in as an appendix, making in all 187. The number of plates in the two volumes is therefore 377. In a note at the end of Vol. II. are the following remarks:—

"Should any of the plants which are omitted, or of which the impressions are from poor specimens, be obtained, a supplementary part may at some future time be added to this work.

"II. P., September, 1859.

A. A."

The foregoing fixes the date when the last of the impressions were secured, and this shows us that they have so far had a thirty years' existence. Whether Talbot had an actual copy of the work before him when he wrote the article we have quoted from we know not; but the freshness and brightness—nay, in some cases, the vividness of the prints would make one almost believe that they had been but recently reproduced. This will serve to convey to the reader how far the permanency of the cyanotype process may be relied on; but before passing on to consider it in detail, it will not be without interest to refer to the paper on which the prints have been produced. In this matter we have only the original water marks to guide us, and although many of the sheets do not show any mark, still we find a very large number bearing the impress of I. Whatman, Turkey Mill, and the years of manufacture are the following:—1843, '45, '46, '48, '49, and '51. There are one or two sheets which have as their water mark, C. Wilmot, 1840.

In the editorial article of *THE BRITISH JOURNAL OF PHOTOGRAPHY* ALMANAC for the current year a very exhaustive account of iron printing will be found, and by referring to what is there said regarding ferro-prussiate and blue prints, the *modus operandi* to be followed in producing cyanotype impressions is made sufficiently clear. The process is one which dates back pretty considerably in the annals of photography. In 1840, or thereabouts, Sir John Herschel demonstrated that light acted on the more highly oxidised iron salts known as ferric, reducing them to a lower state of oxidation (ferrous), and as these reduced products manifest with certain reagents a different series of reactions from what the original substance gives, the action of light is rendered evident in the most pronounced manner. The production of these cyanotype impressions is due to the fact that

while the highly oxidised salt of iron gives no reaction with red prussiate of potash (potassium ferricyanide), the reduced or ferrous salt gives the formation of a blue product, a substance similar in character to ordinary Prussian blue. As is generally well known, paper serving to give blue impressions is to be had commercially, and is largely employed in engineering and other establishments for the purpose of reproducing line drawings. There are two modifications of such paper, the one similar in character to the impressions in *British Alga*, giving a white line on a blue ground; while in the other the lines are reproduced in blue, and the ground remains clear.

The remaining point to be considered in connexion with our volumes of cyanotypes is, Who has been the author of them? I regret that so far I have not been able to find any one who could afford me the necessary information, or could suggest a clue where it might be possible to learn something regarding the authoress. That it was a lady amateur we have the evidence of the paternal dedication. The only thing relating to an address are the initials, "H. P.," at the end of Vol. II. It would be very satisfactory if more details were forthcoming. It is quite clear that only a very few copies could have been prepared in the first instance; in fact, the labour entailed in producing only one copy must have been enormous. We leave it to the readers of the JOURNAL to see if further information be not obtainable. In the meantime, we can only interpret the somewhat mysterious initials "A. A." as Anonymous Amateur. Wm. LANG, JUN., F.C.S.

LENSES.

[A Communication to the Birmingham Photographic Society.]

We propose having a little talk this evening about photographic lenses. It is comparatively easy to talk without saying anything that is to be profitable, and my difficulty is to tell you something you do not know. But I do hope the discussion I shall endeavour to start will bring out some practical knowledge for diffusion among us. That is my object in accepting my present position. I propose to leave out, as far as circumstances will permit, the theoretical and scientific aspect of the subject, which only interests its few, and treat as well as I am able of the practical side of it, that is, the knowledge and use of lenses, in which we must all be interested. At the same time, I strongly recommend all photographers to learn what they can of the theory and principles of photographic optics, as they will the reader grasp the intentions, capabilities, and use of their lenses. I am not going to attempt much history of lenses either, but will speak of them as I find them.

To commence with, I may perhaps point out where a photographic lens differs from any other. If I take a simple spherical lens, such as a magnifying glass, and attach it to a camera, then turn it to some brilliant object, I see fringes of colour around the lights, prismatic colours of course. If I take a picture with it I obviously fail to get sharp outlines, besides finding numerous other ills from spherical aberration, &c. Most of these faults were studied and corrected when telescopes came to be made, long before photography was known. The colour, or chromatic aberration as it is termed, was got rid of by making each lens of two kinds of glass cemented together, one counter-balancing the opposite errors of the other, and so telescopes became greatly improved. I have felt obliged to mention the telescope lens, because the photographic lens is in a sense the outcome of it. The lens I have now described may show a very satisfactory image upon our ground glass, but attempt to take a picture with it and you will find it all out of focus. Strange to say, it is found there may be a chemical and a visual focus, and that the two quite differ. I have no doubt Daguerre found this difficulty, and had to ascertain how far to move his focussing screen to get at the chemical focus. A photographic lens has to be corrected to make the two foci coincide, and I mention this chiefly because plenty of lenses are knocking about to-day where this has been very imperfectly performed, much to the detriment of the lens and the mystification of the tyro. We have got as far now as what is called a single lens (the compound of two pieces of glass). It is now so well understood and simplified that I now can pick up a very decent half-plate photographic lens, an unmounted meniscus, that can be bought in quantities at eightpence each, quarter-plate a shilling. It is such as you find in cheap cameras, and in skilful hands will produce pictures difficult to distinguish from those produced with expensive lenses. It was observed that these lenses, while giving most excellent results in landscape pictures, when applied to straight lines, such as architecture or machine drawings, gave very decided distortion at the margins. When the stop was at the front of the lens the distortion was barrel-shaped, that is, coming in at the corners, while when the stop was at the back of the lens the distortion was pincushion shape, that is, extended at the corners. These faults were got rid of by employing two lenses at varying distances apart, with a stop between them. This form is called rectilinear, and other names with a similar meaning. You will here observe that the stop is in front of one lens and behind the other; this may be why one corrects the other, though I have never observed it in print.

The two lenses forming the combination are often exactly alike, hence the term symmetrical. This form of lens gives us straight lines, hence the term rectilinear. But it has another advantage also, it admits of a

larger stop than a single one does to attain the same depth of focus; though for all its advantages it is frequently inferior to the simple single lens in producing pictorial effect. A portrait lens is one of this combination form, working with extra large aperture, often $f/4$, but it is not a symmetrical, the two lenses are quite different. A wide-angle lens is also a similar form, but to make it cover a plate large in proportion to its focus the lenses are placed closer together, and a smaller stop becomes necessary to give depth of focus, so that wide-angle lenses are not so quick as the ordinary rectilinear, seldom working above $f/11$. However, they are often indispensable for working at short distances, which they do by virtue of their short focus; but as they give an exaggerated appearance to perspective, should never be used when a long-focus lens would do the work. To those who have never done so it is worth while to note what angle means in respect to lenses. I will attempt an illustration on a half-plate. From corner to corner a half-plate measures about eight inches. Many of you possess half-plate lenses of eight inches focus; now we will see what angle they include. If I draw a line from two extremities of our plate to the lens, so, and now note how many degrees of the circle that includes, we have the answer. There are 360 degrees in the circle, and as our diagram shows us a segment exactly one-eighth of a circle, the angle of lens is forty-five, which is practically an admirable one. The widest angle lens I have yet met with is four inches focus to the half-plate; we shall find its diagram shows just a quarter of a circle, which is of course 90° . Wide-angle lenses are usually about 70° to 80° , which would be about five to six inches focus for the half-plate. The angle of a lens has a very direct bearing upon the artistic side of the question, the nearer it assimilates to our own eyes, the truer the effect. I hope we shall hear something about this in the discussion.

And now a few words about stops or diaphragms. Lenses without stops are like heads without brains—you can do very little with them. A stop has various effects upon a lens, mostly beneficial, though I don't wish to convey the impression that the more stop the better, else the cap would be the millenium; on the contrary, I would rather say the larger or the less stopping the better. The margin of a lens is of necessity more inclined to faults than the centre, and a stop acts beneficially in interfering with those faulty rays. It does not effect this by cutting them off, else the same thing might be done by reducing the diameter of the lens itself; but a stop properly placed "turns the rays in the way they should go," and that is sufficient for us to-night. True, stopping down diminishes the light, which is generally the reason for using the largest stop you can. Undue stopping down also makes detail too sharp for most artistic senses. The position of the stop should invariably be determined by the lens maker, and if found to be at fault—such as giving flare spot—should be returned to that individual for correction. Stops are, or should be, marked f so-and-so. For the benefit of those who may not understand the exact significance of those marks I will explain it.

The figure on the stop refers to the diameter of the aperture in relation to the focus of the lens; thus, if we take our half-plate eight inches focus rectilinear and look at the largest stop, we find it marked $f/8$, and on applying a foot rule find that the aperture measures one inch, so that $f/8$ means an aperture one-eighth of the focus of the lens. If you look at the $f/16$ stop, you will find it measures half an inch, or one-sixteenth of the focus length. The great value of this notation is that, practically speaking, $f/16$, or any figure on one lens, requires the same exposure as the same figure on any other lens, thus giving us a ready means of comparing and adjusting over-exposures. Theory also steps in and says that as you increase or diminish the stop the amount of light admitted amounts to the square of the difference, or, in plain language, $f/8$ being twice the diameter of $f/16$, only requires one-fourth of the exposure, or $f/32$, being only half the diameter, requires four times the exposure. In practice I have found that $f/32$ would be over-exposed with four times the exposure of $f/16$, but we must not rush off to blame theory for that—no doubt the philosophers are right in the main, but there are often disturbing influences. I want to know whether any one else has observed the same thing.

Before concluding, I would say that there are several modifications of the foregoing lenses being made now, such as a single lens, with a comparatively wide angle, and a symmetrical doublet working with as large an apparatus as $f/6$, the Euryscope. These lenses are invaluable for special purposes, but are not so universal as the others. I have a triplet lens here; this lens is an arrangement of three achromatics, all of different size and focus; it is perfectly rectilinear, and a splendid lens for most purposes, copying in particular, but it has one great drawback to modern ideas—it is very slow. It dates much earlier than the rectilinear you are so familiar with, and in its day was the best lens to be had.

During the last year or so quite a flutter has been caused among us by the discovery of an entirely new glass, known as "Jena." It places quite a new power in the hands of the optician, and great things have been prophesied. Whatever it may be destined to become, we have not heard quite so much of it lately, and I have not yet seen a specimen myself. I think we are now ready to look for the "moral," and seek an answer to the question, "What lens shall I buy?" That is a very awkward question to be asked. If we are asked "What lenses shall I buy?" the answer is comparatively easy. We have got into the subject sufficiently to-night to see that to satisfactorily accomplish all round work several lenses are wanted, and, as a matter of fact, professionals and all amateurs who can command them employ several lenses to their cameras.

The usual, and I've no doubt the best advice to the one lens man is to buy a rapid rectilinear, or one of the same class, for I should like it to be understood that there are at least half a dozen first-class makers turning out a similar lens, and the qualities of all are so much alike that it takes a much cleverer man than I am to detect the difference. The young beginner with a cheap set invariably has only the single lens to work with, but while he sticks to ordinary landscape or groups, his disadvantage is far more imaginary than real. In fact, as already shown, he may often have an actual advantage. I have necessarily only been able to give a rough outline of my subject, but if its scantiness enables you to commit it the more surely to memory, my efforts will not have been in vain. It is the desire now that you should ask and raise questions, and what I cannot answer others amongst us may. I look forward to the discussion so raised being of far more value than my little paper.

WALTER GRIFFITHS.

LEWES AND SUSSEX PHOTOGRAPHIC EXHIBITION.

LIST OF AWARDS.

Division A.—Class 1. A. H. Webling, silver medal; P. Morris, bronze medal.—Class 2. E. I. Baker, silver medal; W. P. Marsh, bronze medal.—Class 3. Mayall & Co., silver medal; no award of bronze medal.—Class 4. W. & H. A. Fry, silver medal; E. I. Baker, bronze medal.—Class 5. W. P. Marsh, silver medal; no award of bronze medal.—Class 6. A. E. Slater, silver medal; no award of bronze medal.—Class 7. No entries.—Class 8. A. H. C. Corder, silver medal; A. H. Webling, bronze medal.—Class 9. W. & A. H. Fry, silver medal; no award of bronze medal.—Class 10. W. & A. H. Fry, silver medal; E. I. Baker, bronze medal.

Division B.—Class 11. S. Norman, silver medal; A. H. C. Corder, bronze medal.—Class 12. No awards.—Class 13. E. J. Bedford, silver medal; S. Norman, bronze medal.—Class 14. S. Norman, silver medal; D. Blagrove, jun., bronze medal.—Class 15. E. J. Bedford, silver medal; no award of bronze medal.—Class 16. P. Morris, silver medal; J. J. Holloway, bronze medal.—Class 17. P. Morris, silver medal; A. H. C. Corder, bronze medal.—Class 18. J. G. Braden, silver medal; no award of bronze medal.—Class 19. E. I. Baker, silver medal; Mrs. T. H. Cole, bronze medal.

Division C.—Class 20. E. Hammond, silver medal.—Class 21. S. Norman, a bromide enlargement, value 2l. 2s.—Class 22. S. Norman, silver medal; E. J. Bedford, bronze medal.

Foreign Notes and News.

THE difficulties by which the application of photography to the heavenly bodies is surrounded—a subject which gave rise to some interesting discussion in the pages of this JOURNAL a few weeks ago—have received fresh illustration from the unsatisfactory result of the most recent attempts to improve on the previously existing photographs of the moon. The photographs in question were taken at the Lick Observatory, California, where the perfection of the apparatus and the skill of the operators naturally gave rise to the expectation that the results would greatly surpass anything hitherto obtained. Dr. Meydenbauer, of Berlin, however, to whom they were submitted for examination, maintains that no improvement on the smaller photographs of 1865 is apparent. A German contemporary gives the following explanation of this extremely disheartening result:—"Every telescope," it states, "when in position, is subjected unavoidably to small vibrations about its point of suspension, and the larger the instrument the more this is the case. The great lenses of a large telescope do not perfectly preserve their form in all positions; the glass, in spite of its comparative rigidity, being subjected to flexions which spoil the sharpness of definition of the image for photographic purposes. These evils do not make themselves so strongly felt with smaller instruments; hence the comparative excellence of the earlier photographs."

THE publication is announced of a new work by Drs. Franckel and Pfeiffer, on the photo-micrography of bacteria. The treatise in question has been composed under the direction of Dr. Koch, the celebrated authority on bacteria, and will probably become a standard work on the subject.

DR. VOGEL devotes an article in the *Photographische Notizen* to the rivalry subsisting between professionals and amateurs; the jealousy frequently felt for the former by the latter he regards as ungrounded, since professional interests are by no means interfered with by amateurs. He points out that nowhere are there a greater number of musical amateurs than in Germany and Austria, and that, nevertheless, professional musicians earn more in those countries than anywhere else. The large number of amateurs causes music to be more widely appreciated among the public, since to be oneself a performer enables a person the better to estimate the value of any music he may hear.

THE *Photographisches Wochenblatt* will in future be edited by Dr. Meethe, of Potsdam, well known for his researches in philographic optics. He has for years been an energetic member of the Society of Friends of Photography, and of the Union for the Promotion of Photography.

DR. J. SCHNAUSE recommends making trial of anthrarobin as a developer. This body, which was obtained by C. Siebermann through reducing alizarine by means of ammonia, is a yellow-brown body which has a strong absorbing power for oxygen when in alkaline solution. It is not soluble in water, but dissolves readily in alcohol, alkalies, and glacial acetic acid. One would, of course, select the alkaline solutions for experiment.

HERR E. KIEWNING recommends the following method of forcing when employing iron oxalate as a developer, among its advantages being that one thereby avoids the necessity of counting drops inside the dark chamber:—Pour one to two drops of fixing soda solution on to a plate, and immerse this plate in about sixty cubic centimetres of the oxalate solution for one to three minutes; then add twenty cubic centimetres of iron solution thereto. The result is surprising! Under-exposed plates come out quite free from cloud.

HERR LIESEGANG, in a recent number of the *Photographisches Archiv*, gives an interesting account of some experiments which he recently undertook with a view towards rendering images visible at a distance by means of the electric current. The principle of the apparatus with which he experimented is as follows:—The reduction of various salts of silver, and also copper, give rise to electrical currents, and conversely electrical currents under certain conditions can bring about the reduction of these salts. Professor Liesegang arranged a copper plate provided with a coating of copper salts in such a way that an image focussed on it by means of a lens gave rise to currents at different points, varying in intensity with the degree of illumination of that part of the image. These currents being conducted to a second plate, and there similarly distributed, cause reductions of the salt, coating the plate corresponding exactly to the reductions which originated the various currents; that is to say, an image the exact analogue of a photographic image is produced at an indefinite distance from the original object, and this image illuminated and projected on a screen permitted the success of the experiment to be exhibited to an audience.

THE difficulties which have hitherto largely impeded the accurate measurement of the co-efficient of expansion of bodies at high temperatures, the accurate knowledge of which is frequently of considerable importance in the arts, have, according to *La Nature*, been practically solved by the assistance of photography. The principle involved is, of course, the comparison of the photographic images of the body at two or more different temperatures. M. Le Châtelier, who was the first to employ this method, states that by its means accurate measurements down to 0.01 millimetre can be obtained.

AN application of photography, from which the study of clinic medicine is likely to derive considerable advancement, has recently been pointed out by Dr. Eder's organ, the *Photographische Correspondenz* of Vienna. This journal remarks that instantaneous photography has been employed for some time to illustrate works in psychosis and neurosis, and suggests that its employment in hospitals in all phases of illness would enable the exact appearance and peculiarity of the various classes of symptoms to be as it were stereotyped, in a manner which would not fail to be of the highest value as an assistance in diagnosis.

THE Russian photographers are likely to have a brilliant time of it if the accounts recently published of the experiments in gas making from the Caspian petroleum prove correct. For, according to reports, this petroleum gas possesses five times the illuminating power of ordinary gas, is perfectly smokeless, and so white and pure that it may be employed in photography. Surely here is happiness at last to be able to take portraits all night without fear of being blown to pieces by dangerous flash-light powders.

A NEW use for, or rather application of, photography to controlling, namely, the fidelity with which a General's orders are executed in the field, is reported from Belgium. As the occurrence throws an amusingly naive side light in the army discipline of that pugnacious little kingdom, it may be interesting to English readers. A number of photographers followed the movements of the troops, awaiting, with their usual praiseworthy perseverance, favourable opportunities for obtaining instantaneous views. The General in command, observing the labours of the photographers, requested to be permitted to inspect the result, when, to his astonishment, he discovered that the positions taken up were anything but those which he had ordered. That the efficiency of the manoeuvres

was not thereby impaired, and that the General would, but for the aid of photography, have failed to make the discovery in question, are facts which the Belgian papers permit us to divine, though they discreetly refrain from making such a distinct avowal.

Our Editorial Table.

ILFORD "ALPHA" LANTERN PLATES.

SAMPLES of this new plate reached us just when preparing to make some lantern transparencies, and we have had every opportunity of giving them a thorough trial. They possess this advantage, that not being of an exalted degree of sensitiveness the room does not require to be rendered so dark as with others, hence one can see the more readily what he is about. We imagine that they are branded by the makers rather slower than they deserve. For example, they say "the exposure required for a negative of ordinary density will be about three minutes at a distance of six inches from a fish-tail gas burner." We found that an exposure of two minutes proved ample. Possibly our gas is better, or the burner is larger. The development recommended is as follows:—

No. 1.

Hydroquinone	80 grains.
Bromide potassium	15 "
Sulphite soda	1 ounce.
Water	to 20 ounces.

No. 2.

Soda hydrate	30 grains.
Water	20 ounces.

For use take equal quantities of each. After development the manipulations will be the same as for negatives. The longer the exposure, the warmer the tone. A properly exposed plate requires about the same time in the developing solution as an ordinary Ilford plate.

Adhering to these directions we obtained in every instance fine warm tones, with great purity in the lights and depth, without opacity in the shadows.

THE CONVENTION GROUP.

By FRISER GREENE.

To produce a group comprising eighty-three figures on a plate of very large dimensions, each figure perfect and a capital likeness, is no easy task, more especially when it is considered that the subjects are photographers, whose reputation as either sitters or standers by no means equal the average mass of subjects by which they make their own reputations as artists. Mr. Greene has done his work cleverly and well, and we much prize the goodly result of his efforts. He prints them in both platinum and silver.

THE "PREMIER" TRIPLE LANTERN.

By J. H. STEWARD.

This apparatus has been designed and constructed to give the greatest possible rigidity to the fronts, with facilities for all necessary adjust-

ments and centring of lenses of various foci; also for extra convenience in using the same. It is a departure from the plan in

general use for some years past of supporting the front from the stage only. It will be seen from the accompanying illustration that there is a supporting frame in front which permits of connecting the rack bars with it, and the rising screws and clamps in the attachment make an absolute certainty of the adjustment for true inclination to get coincidence of discs, there being a lateral as well as vertical movement. It, therefore, can be thoroughly relied on to retain its truth.

The "Premier" system is also applied to the Biunial. Mr. J. H. Steward, 406, Strand, is the patentee and maker of this admirable instrument.

INTRODUCTORY LESSONS IN QUANTITATIVE ANALYSIS.

By JOHN MILLS and BARKER NORTH.—London: Chapman & Hall, Limited.

This manual presupposes a knowledge of qualitative analysis, or that branch of chemistry by which we ascertain the constituents of which a body is composed. The whole principles are entered upon, and numerous examples given. The manual will be invaluable to the young chemist.

IMPROVEMENTS IN PHOTOGRAPHIC SHUTTERS.

No. 17,298. GEORGE SYLVESTER GRIMSTON, Claremont, Glenluce-road, Westcombe Park, Greenwich, S.E., Kent.—September 28, 1889.

THIS invention has for its object the improvement of instantaneous or time shutters for photographic purposes, and consists mainly in the construction and arrangement of the releasing and detaining mechanism; and is applicable to those shutters which have a reciprocating action of the sliding shutter, and also to those which have a revolving action of the shutter, and can be applied to those shutters which are situated outside the lens combination as well as to those which are used within the lens combination.

In applying this invention to a reciprocating shutter, in which the reciprocating action of the sliding shutter is caused by the revolution of a crank or similar device actuated by a spring, I use a crank plate or disc, to which the sliding shutter is attached in the usual way by means of a crank pin. On the edge of this crank plate are placed notches or detents for holding or detaining the sliding shutter, two notches for holding it when set ready for action and one for detaining it when fully open. This latter notch can be used for holding the sliding shutter when fully open for focussing. These notches will be hereinafter called Nos. 1, 2, and 3, according to the order in which they come when setting the shutter ready for use. These notches engage with a pin on a lever connected with a pneumatic pump or other device for actuating the lever the pin on the lever being kept up against the disc when the lever is in its normal condition by means of a spring. From notch No. 1 to notch No. 2 a thin strip of metal, forming a guide, extends round the outside edge of the aforesaid crank disc, and at such a distance from it as to allow of the said pin passing freely between it and the disc. This strip leaves off just short of notch No. 1, and has its end there slightly turned up towards the disc. Notch No. 3 is just beyond notch No. 2 (these two being diametrically opposite on the crank disc to notch No. 1), and has its edge at the same distance from the centre of the crank disc as the outside of the aforesaid metal strip.

The action is as follows:—If it is desired to give an instantaneous exposure the crank disc is turned round until the pin on the said lever engages into notch No. 3; on disengaging the pin from this notch the disc begins to revolve, and the said metal strip comes between the pin and the disc, thus preventing the pin from engaging into notches Nos. 1 and 2. Consequently the disc performs a complete revolution, opening and closing the sliding shutter. If now it is desired to give a lengthened exposure the crank disc is turned round until the pin on the said lever engages into notch No. 2. On disengaging the pin from this notch, the pin pressed by the said lever endeavours to force itself farther away from the disc, but is detained by the said metal strip, which, as the disc revolves, delivers the pin into notch No. 1, which thus holds the sliding shutter open until a second pressure on the lever releases the pin, when the disc completes its revolution and closes the shutter. If before the pin is delivered into notch No. 1 by the said strip there should be any pressure on the said lever, the end of the strip being turned up as aforesaid prevents the disc from revolving when the pin reaches this turned-up end until such pressure is relieved, when the pin is delivered into notch No. 1 as aforesaid. In order to diminish the shock or jar when the said notch No. 1 hits against the said pin the lever is mounted on a spring, thereby acting as a buffer.

In applying this invention to a revolving shutter the said disc forms the shutter, having an opening in it for giving the exposure, the notches and strip being arranged in the same manner as for the reciprocating shutter hereinbefore described.

It will thus be seen that when the apparatus is set for an instantaneous exposure one pressure on the lever causes the shutter to open and close rapidly, and if set for a lengthened exposure one pressure opens it, and it remains open until the second pressure releases it and the shutter closes.

Claims:—1. In photographic shutters the arrangement and combination of

the notches 1, 2, 3, and the guide 1, for giving an instantaneous or prolonged exposure, substantially as hereinbefore described and illustrated by my drawings. 2. In photographic shutters the general combination and arrangement of parts, substantially as hereinbefore described and illustrated.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

OCTOBER 22,—Technical Meeting—Mr. John Spiller (Vice-President) in the chair.

The display and explanation of the apparatus included in the Society's exhibition formed, as in former years, the subject for the attention of the members at this meeting.

Mr. WINTER, representing the firm of Mawson & Swan, showed the detective camera which was described in THE BRITISH JOURNAL OF PHOTOGRAPHY last week. The method of stowing the exposed and unexposed plates, and of bringing the latter into position for use, was duly appreciated, and the arrangement for keeping the lens closed and invisible, except during the moment of exposure, elicited much approval.

A camera by Messrs. Sands & Hunter, which, although of whole-plate size, closed to two inches when packed, and another by the same makers which was slightly thicker, but in which the baseboard protected the focussing screen when not in use, were next shown.

Mr. S. SAMUELS next explained the use of his detective camera, which was for a dozen 5×4 plates, and which he stated contained nothing of an automatic kind. Everything was done by hand, the plates being kept in a reserve box at the back and lifted into place by the fingers acting through a bag of black material. He considered it a point to be able to use lenses of various lengths of focus with the one camera, and had arranged this apparatus accordingly. Another camera shown by Mr. Samuels was intended for use in the studio, and was furnished with a holder for eight plates.

Mr. W. E. DEBENHAM inquired whether there was not a likelihood of dust spots showing themselves upon plates manipulated through a bag.

Mr. SAMUELS had not found it so.

Mr. Wormald's copying camera for enlarging, in which a printing frame is substituted for the dark slide, was then exhibited and described, and was followed by Messrs. Swinden & Earps' detective camera, which has been awarded a medal, and which has been described on page 666.

Mr. Shew next showed a detective camera, one of the points of which was that there was a "pusher," by means of which it could be felt whether or not the plate was in its proper position. Another point was that if a plate was broken, stuck fast, or suspected to be damaged, the changing back (containing a dozen plates) could be removed, and the one spoil plate taken out without stopping the working of the remainder.

The Ferrero film carrier was then shown, and was followed by Marion's exhibits, including Greuley's shutter, which opens and closes from the centre and is very light; and an arrangement for printing lantern slides from half-plate negatives by means of a lens set at the fixed focal distance in a square tube or box of millboard, one end of which was furnished with a holder for lantern-size plates, and the other end with a carrier for the negative.

At the conclusion of the meeting Mr. W. England exposed plates directed at the medallers, who were illuminated by flashes from two of Schirm's magnesium lamps.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 17,—Mr. W. E. Debenham in the chair.

Mr. F. A. Bridge showed an instantaneous shutter of French manufacture, called *L'Automatique*. The opening was from the centre, what is known as of the diaphragmatic kind, and the apparatus was very light. The most striking thing in connexion with the shutter was that it was always ready for use without resetting; the pressure of the pneumatic ball actuated the movement, and after closing left it ready for another exposure.

A question being asked as to the best position in which to use such a shutter, the CHAIRMAN replied, either between the lenses or as close to one of the components as possible.

Mr. F. P. CEMBRANO showed a detective camera of exceedingly light construction, weighing, with six double plate holders for quarter-plates, only about three pounds. The sheaths or plate holders were of a peculiar construction, ingeniously contrived to be but little thicker than the plates contained in them, and the cut-off of light appeared to be very complete; but Mr. Cembrano noted what he considered a weak point in the durability of the sheaths, in that the line of union of the sheet-metal sides with the tubular top was too fine for strength. He had worked very satisfactorily with the camera, but had found that the only position in which he could secure steadiness was that of being held under the arm, pressed against the side of the body. There was no finder to the camera.

Mr. A. HADDON thought that the camera should have a finder. A camera held in the position indicated by Mr. Cembrano was most unfavourably placed

for dispensing with a finder. He also considered that a button was better for releasing the shutter than a lever such as this camera possessed.

Mr. CEMBRANO agreed that a finder was desirable; he could not compose the picture so well without it.

Mr. T. E. FRESHWATER had some eikonogen that had been kept open for some time before being used. It had consequently changed to a light chocolate colour, and he had not been very successful with it in developing negatives. For bromide paper, however, it worked very well, and the prints did not require clearing with acetic acid as when developed with ferrous oxalate.

Mr. A. COWAN said that for bromide prints and for lantern slides, especially the latter, there should be a little bromide used with eikonogen developer; a very small quantity sufficed—one or two drops of a ten per cent. solution of bromide of potassium to the ounce of developer. Mr. Cowan then inquired whether it had been noticed that if a plate was being developed with pyro, bromide, and ammonia, and carbonate of ammonia was added, the development, instead of being accelerated, as might have been expected, was retarded. He had found about double the time of development to be then required.

Mr. H. H. SUMMERS mentioned a recent experience of his. He had a parcel of extra rapid plates upon which he could get nothing but fog when using sulphite in the developer; the same plates worked well with a developer containing no sulphite.

It being remarked that crystals of sulphite of soda were very apt to become decomposed in the presence of air, Mr. ATKINS said that he filled his bottle of dry sulphite with common coal gas, and used a smear of vaseline round the stopper to prevent access of air.

Mr. HADDON inquired whether it was possible to develop several papers in succession with hydroquinone without stains, and whether on such stains occurring there was any means of removing them.

Mr. SUMMERS always found after developing several prints that the later ones became stained. He had tried acid baths to remove them, but without effect. He also inquired whether there was any radical difference in the Aristotype or gelatino-chloride papers in the market. With one make he found that a mere trace of hyposulphite of soda—half a grain to ten ounces—added to the sulphocyanide bath entirely stopped toning action, whilst with the other paper the addition of hypo was recommended and worked well.

Mr. J. S. Teape was elected a member.

CAMERA CLUB.

OCTOBER 17,—Mr. J. Traill Taylor in the chair.

A paper was read by Mr. LYONEL CLARK on his platinum toning process, a demonstration being also given.

Previous to the lecture some very fine platinotype pictures (copies and original work) by Mr. Burchett were shown, and the HON. SECRETARY drew attention to the special evening at the Pall Mall Exhibition in aid of the Photographers' Benevolent Association.

Mr. CLARK, in his paper, traced the history of platinum processes, and proceeded to describe in detail his treatment of various papers and textile fabrics—salting, sensitising, printing, and toning, &c. A large number of exposed prints on Whatman papers, silk, and on satin jean were toned and fixed before the meeting. Others brought by the lecturer were passed round to show what was possible to the process.

Messrs. F. W. Edwards, Davison, Humphery, Gifford, Friese Greene, Braham, J. King, E. P. Robertson, Major F. Nott, and the Chairman made remarks upon the subject. The chief discussion turned upon permanency, and upon the advantage of having power to obtain different colours in printing deposits, also the effect of using rough paper for certain subjects.

On Thursday, October 31, a discussion upon *Eikonogen* will be opened by Messrs. H. M. Elder, M.A., and Lionel Clark. Meeting at eight p.m.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

OCTOBER 15,—Mr. W. T. Coventon in the chair.

An interesting series of views in India, taken and presented to the Society by Mr. F. Duusterville, of Madras, was handed round and much admired.

A letter was also read from Mr. W. P. Dando, in which he offered the use of a dark room to any members visiting Paris.

The officers for the ensuing year were then nominated, and some alterations in the rules proposed.

Mr. B. B. FULLER asked the easiest means of removing silver stains from a gelatine negative.

Mr. J. OAKLEY recommended immersing it again in the hypo bath.

Mr. T. LAWDAY recommended rubbing the parts with a tuft of cotton wool saturated with a solution of cyanide of potassium—a piece about the size of a pea being dissolved in half an ounce of water.

Mr. G. J. CLARKE had found a strong solution of cyanide of potassium with a few grains of iodine added very useful for removing stains or bleaching yellowness.

Mr. CLARKE then read his paper on *Enlarging for Amateurs*, and, in introducing his subject, considered it the duty of all amateurs to bring forward their experiences at Societies' meetings and overcome that reticence or modesty which frequently kept them silent. However trifling the experiences might appear, they would probably be of use to some one, and in some cases might even be serviceable to the professional members. He proposed to put the subject as simply as possible before the members, and dealing only with enlargements on bromide paper and describing the apparatus required for daylight and artificial light. Having read of solar cameras and artificial light, he came to the conclusion that a large looking glass and other elaborate arrangements were necessary to the former, and a magic lantern and large condensers for the latter; in addition to this, large trays were necessary for big enlargements, the whole making an expensive outfit. His own enlarging apparatus, which was a home-made one, was shown on the table, and was quite adapted to his requirements; enlargements made by it were also shown. It consisted of a lantern body made of mahogany, with four and a half inch condensers, and to the front two sets of bellows were fitted, the hinder one permitting of the negative being brought nearer to or carried away from the condenser, and the front one allowing

the lens to be placed at its proper distance in front of the negative. The light used in the apparatus was a triplexicon lantern, although any other light could be used with proper arrangements. There was also an arrangement by which the lens and sliding front of an ordinary camera could be readily placed in position. For economy's sake, the cheap Japanese trays one sees in shop windows were used for developing, and when they became a little worn a coat of Aspinall's white enamel was given. He had heard it suggested to make a tray of a large sheet of millboard supported on a wooden bottom, turned up all round the corners, which should overlap, and fastened with paper clips; the dish is then covered all over inside with melted wax candles. Some of his earlier trays were made of wood, the sides and bottom nailed together, but before fastening, brown paper soaked in paste was placed between the joints, and when nailed together all the crevices were filled in with putty and the inside and outside enamelled; these were also used for washing prints. For daylight enlarging, a shutter was made of match boards to fit the window, and a hole twelve by ten inches cut in the centre, which was then surrounded with a frame a few inches deep placed near the edge. Having the framework of an old 12x10 camera, it was fitted with bellows made of card-board and covered with American cloth, the negative being placed where the dark slide should be, and the back portion with the negative brought close up to the aperture in the shutter, stray light being cut off by the frame fastened round it. To support the camera, a shelf was fixed to the bottom side of this frame by means of a thumbscrew, and supported in front by a moveable strut. For a reflector, a small shutter the size of the twelve by ten-inch opening was hinged at the bottom to the outside of the aperture, and coated with white enamel, and in cloudy weather this was covered with cartridge paper to avoid uneven reflections. This reflector could be placed at any angle by means of a cord passed over a small Venetian-blind wheel in the right-hand top corner of the shutter to the inside of the room. To use as a dark room, the reflector closed the aperture entirely, and a small red window, which could be covered, admitted light to work by. The screen for the bromide paper consisted of a drawing board mounted on a frame easel with two legs, and pegs allowed the position to be altered. The ferrous oxalate developer was used, and a full exposure and slow development advised, beginning with the full quantity of oxalate and about half the usual quantity of iron. A red glass cap was used to cover the lens, and this allowed the paper to be placed properly in position. For vignetting, a card was recommended with an aperture nearly the shape of the figure and moved to and from the lens. Shading the very deep shadows was also advised for about a third of the time allowed for exposure.

Rev. E. HEALY had used hydroquinone for developing bromide paper—strength, about three or four grains to the ounce.

Mr. OAKLEY advised exposing the paper wet and placed on the front of a piece of glass; focussing could be done on plain paper and the exposed piece put into the developer while wet.

A hearty vote of thanks was proposed to Mr. Clarke for his paper.

Tuesday, November 5, will be the annual general meeting of the Society; November 19, a lantern evening; and on December 3 Mr. W. Bishop will read a paper on *Making Lantern Slides*.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

OCTOBER 14.—Owing to illness, Mr. Fry was unable to give the demonstration of *Enlarging*; the evening, however, was profitably occupied by Mr. E. T. HUSKOCK, who, at extremely short notice illustrated lantern slide making and opal printing, and explained the various operations.

Mr. Fry has expressed his willingness to give his demonstration on Monday next, October 23. Visitors interested are invited to attend.

DERRY PHOTOGRAPHIC SOCIETY.

OCTOBER 15.—Mr. F. G. PIERPOINT, of the Leicester Photographic Society, gave a most interesting and enjoyable description of the many beautiful places of interest on the Thames from Oxford to London, illustrated with lantern slides made by himself, from negatives taken *en route*. The excellence alike of the lecture and slides was proof of what a great interest Mr. Pierpoint takes in his work.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

OCTOBER 1.—The President (Councillor Firth) in the chair.

The SECRETARY presented the report of the Council for the past year, which showed that excellent work had been done, progress made, and that it was able to hold the position the Society had gained among kindred societies for theoretical as well as practical work. The membership roll had been increased, and the average attendances at the ordinary meetings showed a marked improvement on any previous year. The financial position of the Society was also in an encouraging condition, a good balance remaining in the Treasurer's hands.

The printed Treasurer's account, after further oral confirmation by the Auditors, was taken as read and adopted.

The following gentlemen were elected officers for the ensuing year:—*President*: Mr. R. J. Taylor. *Vice-Presidents*: Messrs. G. Bromley and T. Firth. *Council*: Messrs. J. W. Charlesworth, A. Davy, A. Reynolds, W. T. Furniss, and Jonathan Taylor. *Treasurer*: Mr. Bradley Nowill. *Hon. Secretary*: Mr. E. Beck.

The SECRETARY announced that he had succeeded in obtaining promises of papers or demonstrations from gentlemen for every ordinary meeting during the year, and a printed programme would shortly be issued to each member.

HASTINGS AND ST. LEONARDS PHOTOGRAPHIC SOCIETY.

A MEETING took place at the Brassey Institute at eight p.m. on October 14.

The proceedings were commenced by the chairman (Mr. W. Shuter) receiving the report of the Judges appointed to judge the results of the Society's summer excursions. There being only a few exhibitors, the original idea of making each excursion a competition was given up, and only two awards made, viz., to A. Brooker (Hon. Secretary), for the best photograph sent in, and to J. Downborough, for the best collection of photographs.

Mr. JONES, the demonstrator from the Platinotype Company, was then called upon, and read a paper on *Platinotype Printing*.

Correspondence.

Correspondents should never write on both sides of the paper.

PHOTOGRAPHS IN PRINTING INK.

To the Editor.

SIR,—Your correspondent, Mr. W. H. Davis, in this week's JOURNAL has probed a serious subject, one which will bear considerable balancing of *pros* and *cons* to properly clear the matter up as to where the cause of our backwardness lies in the production of photographs in printing ink.

Having had a lengthened experience, extending over the last forty years, I can endorse every word your correspondent says. There is one vital point, however, which must be considered as the main factor of our backwardness when compared with American or Continental press photography. I refer emphatically to the insatiable thirst for cheapness which develops itself with increased energy as the various processes become more practical. It is quite a common experience to find publishers and managers of extensive printing houses accepting work, not because it is first class and the best of its kind, but because "it is cheap and will do well enough." Take for instance the so-called "ink photographs." No other country in the world would tolerate such work; yet, because it is cheap and displays a ghost of the original photograph it is accepted with thankfulness. But there is a still more potent cause to be looked at closely and to which your correspondent truthfully refers, namely, the niggardly remuneration offered for talented experts. An experience of many years of American usage enables me to contrast the condition of things there and in this country, very much to our discredit. The American employer or publisher is continually on the alert for *excellence*: if the artist, workman, or process be not of the very best and newest thing out, he won't accept him or it; but, alas! with us, if either artist, workman, or process cannot undertake to turn out acres of work, and at a cheap rate, he is ignored, and they fall back upon what the "smart boy" and the "handy man" can give them.

No doubt we have a few rather large establishments in this country engaged turning out collotypes and zinc etched blocks of photographs, and if I were able to name the remuneration which the brains and hands have been paid for setting their works agoing and the carrying of it out, it would give us a solution of the cause at once.

It is a positive fact that parties contemplating starting the business of press photography in this country actually prefer to stumble into the various processes, blindly relying on the help afforded by a hand-book or photographic journal, rather than pay an expert for his services to start them in a profitable and perfect manner, or to share with him a portion of the business profits. The fact reveals itself, the gulf that separates employer and *employé* in this country is much wider than it is found either in America or on the Continent.

JOSEPH LEWIS.

Dublin, October 21, 1889.

AMATEURISM.

To the Editor.

SIR,—I am sure the better middle class of professional photographers are grievously injured by amateurism and by what pretends to be so. I am surprised a smothered feeling of this kind is so long pent up. It would, I think, do good, and clear the air, to have half a dozen good men speak out. Hundreds—ah! thousands—of men there are whose all is invested in their business—its plant, its connexion. They have to pay high rents for situation, they have to keep an effective staff, they are photographers, and, having been so all the best part of life, are that alone. They must stick to the holding; no other phase of commercial life would likely open up, or, if it did, would they be suited for it? A set of men have arisen who call themselves amateurs, and who yet sell their goods and pocket the money. Another set, under the name of charity, think it right to injure their neighbours by doing work the trader depends upon, and giving the proceeds to the various schemes they incline to support. To such an extent are these things done, the trader is being pushed to the wall by both. There is no law against it; men claim a legal and moral right to act thus. They even claim to be charitable by ruining their neighbours.

Sir, if there be no other law to prevent this evil, which is sowing seeds of bad blood between two classes of men, can no law of etiquette be established to abate it? Surely gentlemen will consider the peril and so declare themselves and act as to avert it. You, Sir, know I am what I sign myself,

AN AMATEUR.

COVENTRY AND MIDLAND PHOTOGRAPHIC EXHIBITION.

To the Editor.

SIR,—I should be obliged if you will make it known through the medium of your valuable paper that, in deference to many expressed wishes, and on account of many applications for particulars arriving rather late, the Council have decided to make the last day for receiving entries and exhibits Saturday, October 26.—I am, yours, &c.,

October 21, 1889.

FRED. W. DEW, Hon. Sec.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange ten-inch burnisher in good condition for chair, wall, or background. Difference adjusted.—Address, GERMAN, Tortay Terrace, Paignton.

Wanted, Luxograph or other good lantern for night photography; exchange, tricycle, sewing machine, photographic materials, silver watch, &c.—Address, HOPKINS, Photographer, 9, Market-street, Exeter.

Will exchange James's triple magnesium lamp, one ounce of magnesium powder, Cowan's changing box for 10x12 plates, and large glass dipping bath; wanted, studio table, camera stand, backgrounds, or studio accessories.—Address, A.B., 17, King's-road, Upton-park, E.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

HENRY BRADSHAW.—If you send the lens we shall then see what is wrong.

PYRO (Birmingham).—The specimens enclosed are produced by the ordinary collotype process.

ARCHITECT.—If the photograph can be taken from the highway, no permission is necessary, the local photographer notwithstanding.

A. BONSER.—No doubt the pictures are copyright, and it would be an infringement of it to make lantern slides from them. See reply to "Copy."

A. DEARDEN.—The stains arise from imperfect fixation, and not from the washing. More care in the fixing is all that is necessary to avoid the evil in future.

H. F. W.—The Miesenbach Company or Messrs. Waterlow will supply type blocks from a landscape negative. These blocks may be printed with ordinary letterpress.

EYES.—You appear to be suffering from mild intermittent astigmatism. Rest the eyes as much as possible, and when at work assist the eyes with an ordinary magnifier. If you have a good oculist in your neighbourhood you had better consult him.

PERCIVAL SOAMES.—The bottles may be had from any druggists' sundryman, but how they can be used for enlarging we are unable to say. In what direction do you wish to use them? Unless we have further particulars we cannot say what they should contain.

T. G. S.—I. When next we see Mr. Starnes we shall inquire respecting the first query.—2. The collodion must be very contractile indeed if its tendency to slip off cannot be met by a rather strong substratum of albumen or of alumed gelatine. Try also treatment with powdered French chalk.

SEA GULL.—Edwards's and Cadett's plate-coating machines are those used by the best plate makers who coat by machinery. Those who coat bromide paper generally use apparatus of their own design. So far as drying arrangements are concerned, they must be designed according to the requirements of the building.

E. J. B.—Evidently the shutter is too quick for the plates. All the pictures enclosed are very much under-exposed. Either quicker plates or a more rapid lens must be employed. We do not see that it would do to set the shutter to work slower, as in all the examples sent there is a visible movement of the wheels shown.

A. R. SXELLING.—The page is misquoted; on reference to that which you give we find no such formula. However, we imagine the proportion of water is not of much importance; the stronger the solution is made the quicker it will act, and *vice versa*. We believe the print washer referred to answers well, though we have had no practical experience with it.

PRINCIPAL.—The premium for apprenticeship in the photographic profession is no fixed sum; it depends upon the status of the establishment to a great extent. Of course the highest class houses would require a higher premium than third-rate ones. The salary, again, is a matter of mutual arrangement, and in most cases is dependent upon the premium paid; there is no fixed rate.

B. R.—So far as the photography is concerned, the work is very good, but in nearly every instance the point of sight is badly chosen. In some of the examples the work is completely spoilt through this. To an artistic eye, 3, 4, and 7 are positively painful, notwithstanding the good photography. Study the artistic side of the question, and your work will be exceedingly good.

COLLOTYPE (Cape Town).—1. You had better get a work on the subject, such as Husnik's or Vidal's.—2. So far as we are aware, no firms here supply complete outfits for the different processes you mention. If you obtain the works referred to—which may be had through German and French booksellers—you will see what is required, and can then order.—3. A hot climate increases the difficulties in working very materially; indeed, in some instances to such an extent as to make it impracticable except at night or in the early hours of morning.

W. A. MEIGH writes: "I shall be very much obliged if you will be kind enough to criticise the enclosed prints, both as regards the printing and toning. Do you consider the colour of the tone to be due to under-printing, or does the fault (if there is one) lie in the toner?"—The fault in the prints appears to be due to the negatives. They are both under-exposed and over-developed. Better results from them may, however, be obtained, we imagine, by using a paper which yields softer prints. The prints sent are on a paper which seems to have a tendency to hardness.

A. M.—1. Willesden paper trays will answer very well.—2. You cannot do better than follow the formula supplied with the plates for a normal exposure, and using more bromide or more ammonia, according as the negative has received more or less than the proper exposure. If the developer be made as concentrated as proposed we should imagine there would be some risk of the ammonia bursting the bottle in a hot climate if it were securely stoppered. Ten per cent. solutions are very convenient to use. Bear in mind that a drop is supposed to be equal to a minim, and measured minims are a more reliable quantity than drops.

COPY writes: "Kindly let me know, through the JOURNAL, how the law stands with regard to copying engravings and other pictures, and how I am to know which are copyright and which are not, as I should like to copy some for sale and private use. A man called on me with a fine collection of copies from most of the best and latest engravings, offering them for sale at 3s. 6d. each; they were about 15x12."—The law is simply this:—Any one pirating a copyright work renders himself liable to a penalty of 10*l.* for every copy issued. A register is kept at Stationers' Hall in which all copyrights are entered, and from this it may be ascertained whether any work has been registered. It may be taken for granted that all modern engravings are copyright. There are plenty of piracies now being offered for sale.

✂ The Editor once more reminds his friends that the ALMANAC is now being prepared, and he will esteem it a favour if they will forward their contributions by November 1. He cordially thanks those who have already spontaneously sent articles. Contributors will please write names and addresses distinctly, so as to ensure their early receipt of a special library edition of the work.

PHOTOGRAPHIC CLUB.—The next meeting of this Club, Wednesday, October 30.—First lantern meeting of the season.

INTERNATIONAL CONGRESS ON CELESTIAL PHOTOGRAPHY.—There was a preliminary meeting of this Congress at Meudon on September 20, to consider the programme that had been drawn up by the Provisional Committee. A few slight alterations were made in the original scheme, but the details of the work were not entered into. It was, however, decided that the greatest latitude should be allowed in the choice of instruments, and that each observer should employ that instrument to which he was accustomed, having no regard to uniformity. In order to indicate the spectroscopic work included in the programme, a change in the style of the Congress was agreed to. It is henceforth to be the "International Congress on Celestial Photography and Spectroscopy."—*Nature*.

THE ASTRO-PHOTOGRAPHIC CONFERENCE.—The *comptes rendus*, containing the full proceedings of the above Congress, which met at Paris during the past month, have not yet been received. The following, however, are some of the points decided by the Permanent Committee:—The centre of the plate is to be pointed not more than 5" distant from the selected point in the heavens, the size of the plate to be 160 millimetres square. The size of the field adopted was 2" square, whilst the *réseau* is to be 130 millimetres square, with lines 5 millimetres apart. The amount of overlapping decided upon was 5'. Vogel has undertaken the construction and verification of the *réseau*. The distribution of the work among the co-operating observatories has been completed, and to Greenwich is allotted that from declination +48 to +40. Plate glass only must be used for the plates; the chemical formula, however, is left open. The sensitiveness for the chart and for the catalogue is to be the same. *Réseau* to be used in both series. A series of standard plates will be prepared by the Paris Observatory, and the time of exposure must be adjusted so as to compare properly with these standards. There will be one or more *bureaux* established for such observatories as cannot measure their own plates.—*Nature*.

No. 1539. VOL. XXXVI.—NOVEMBER 1, 1889.

AMATEUR DARK-ROOM APPLIANCES.

No. I.

PHOTOGRAPHY would be a much more pleasurable pursuit, no doubt, to a great many amateurs if it were not for the troubles that attend the provision of a dark room. It is not every amateur who is able to set aside a room specially devoted to photography, for even where perhaps the mere accommodation is available, the household "authorities" have to be reckoned with before so radical an alteration can be permitted in the domestic arrangements. Even those who possess the necessary room or "sanctum" too frequently either attempt to render it available for a great variety of purposes, or, dedicating it to dark-room purposes alone, fail for some reason or other to make the most of it by fitting it up properly. In either case the simplest operations in development, or even changing plates, become a trouble and a bore, and grow to be dreaded rather than looked forward to with pleasure.

But perhaps we are correct in supposing that a very large majority of the amateurs of to-day are not in a position to command a special dark room, for modern town houses are not built upon the same lines of the "Moated Grange" of bygone days, with its mysterious passages and corridors haunted by the family ghost and leading to unused wings containing waste space enough for the working of a considerable business. Ground rents are too high nowadays to permit of the luxury of many useless rooms, and compact "flats" are more in the order of things. Then, again, what proportion of the vast army of amateurs is to be numbered on the bachelor side? Bachelors, too, of the solitary description, with no more space than is necessary for actual living purposes, if, indeed, its extension would not add materially to mere comfort without at all bordering on luxury. Here, again, photographic manipulations must be carried on under the greatest difficulties, and it is no wonder that the establishment of a more or less complete dark room is becoming a feature in connexion with modern clubs and societies.

With a little method, however, and at no great expense, a perfectly comfortable temporary dark room may be provided under the most unfavourable circumstances, even though the accommodation be limited to the "bed sitting room" so frequently advertised in the daily papers, though it is true the arrangements must then be such a combination of simplicity and efficiency as to remind one of the wonderful piece of furniture that formed a bed by night and a chest of drawers by day.

Yet, after all, even the "one-roomed" amateur so fitted up is working at a great advantage as compared with many hundreds in the past, who, whether at home or when travelling,

were compelled to work under makeshift conditions. How much of the best dry-plate landscape work of twenty and more years ago was developed in hotel bedrooms or perhaps less convenient places, we wonder? Some of our leading professional landscapists could perhaps tell stories of their experience that would put to shame some of the luxurious grumblers of to-day; while, at the best, working wet collodion in a tent was an undertaking compared with which the development of gelatine plates at home, under *any* circumstances, must be child's play indeed. We have seen many an amateur of the olden time, after a day's outing with the camera, settle down "after tea," perhaps at the same table at which he has just satisfied nature's requirements, or perhaps in the smoking room, if one existed, and having spread a newspaper over the table, turned the gas down low and surrounded it with a paper screen, produced developing materials, and set to work.

It would, perhaps, be a little inconvenient to work in that manner now, on account of the comparatively greater amount of washing required by gelatine plates, and also the greater care necessary in the matter of light. We shall assume then, first of all, that the amateur can temporarily devote to his purpose a bed, dressing, or, perhaps best of all, bath room. The last simplifies matters very considerably so far as the water supply is concerned, and, indeed, leaves little to be provided except the lighting arrangement.

This, whether for temporary or permanent purposes, is easily arranged. Two or three thicknesses of black twill or silesia strained tightly over the window by means of loops, or rings, and nails provided for the purpose will effectually darken the room if artificial light is to be employed; or, if daylight is to be the means of illumination, a square can be cut out of the opaque material and filled in with suitable non-actinic fabric according to taste. The screen of twill will however, after being a little time in use, stretch slightly, and so cause trouble by admitting streaks of light at the side, entailing a considerable amount of pinning and dodging every time it is used. It is better, therefore, to construct a light frame to fit into the window and to strain the flexible material upon this. The screen thus formed is easily removeable and occupies but little space; when required it is quickly fixed tightly and securely in position by means of three or four buttons, or the same number of sash screws.

Instead of textile fabric, paper may be employed to form the screen, and forms a most economical and perfectly efficient substitute. If the window be small, or if arrangements be made, as will be described, for curtailing when necessary the amount of light admitted, the whole of the wooden framework may be covered with a couple of thicknesses of the ruby paper sold by most dealers for the purpose. This should be damped

thoroughly, not *soaked* in water, as the colour is frequently very soluble, and when quite limp stretched as tightly as possible on to the frame, using thick paste or glue for the purpose. The two thicknesses should be attached separately to the opposite sides of the wood frame, thus leaving a space equal to the thickness of the wood between them, by which arrangement there is less chance of white light penetrating through minute punctures. When dry, the paper should be literally "as tight as a drum." It may then be oiled or rubbed with vaseline, but the operation must be carefully performed, or the tightly strained paper may be broken. Such a screen, in fact, requires constant care to avoid injury, though in case of accident it is easily repaired by pasting on a patch of the same paper if the appearance be not objected to.

A much stronger job is made by using stout brown paper as the basis, cutting out a square after it is dry and pasting the ruby medium over the aperture. If two thicknesses of the brown paper be thoroughly wetted to stretch them to the utmost, then laid on the frame separately with good paste, and well rubbed into contact, they will form, when dry, a foundation as "hard as a board" and nearly as strong, and the finished screen will bear a great amount of rough usage.

In the case of a large window, such as that of an ordinary bedroom, it will be convenient to form the screen in two sections, the separate frames corresponding in size with the window sashes. The edges of junction should be rebated to fit one another, so as to lessen the chance of light getting in; and, as an additional advantage, they may be hinged together, which will assist in keeping the joint close and enable the two to be folded together when not in use. It will be a matter for choice how to cover the frames, whether with opaque material with a small ruby window, or wholly with ruby medium, so as to admit more light. The latter is undoubtedly the preferable plan when the room has to be used for purposes other than development, but it will then be judicious to provide an opaque blind, which may be drawn down to reduce the amount of light when very sensitive films are under treatment.

The best material for the blind is stout silesia, obtainable at any dealer's in tailors' materials at eightpence or ninepence a yard, about forty inches wide. But as this material will scarcely harmonise with the appearance of the other blinds of the house, it will be well to let the arrangement form part of the temporary screen. This is easily done by affixing the blind roller and furniture to the upper portion of the wooden frame. To avoid any inconvenience that might arise with a hinged frame from the cord being strained over the two sections, it is better to employ the "patent" roller ends, which work with a single cord and without rack, the blind descending by its own weight and winding up the cord in its fall.

The additional trouble involved in this blind arrangement is amply repaid in the extra convenience arising from the increased amount of light available when required. Nothing is more trying than to have to grope about in unnecessary darkness, and to manipulate slow plates or slower bromide paper in the same dim light as extra sensitive films is not only needless punishment, but is actually detrimental to the character of the work done in the case of enlargements, since it renders it impossible to accurately judge the progress of development. The power, therefore, of modifying the light to suit the work on hand will be thoroughly appreciated, and should be provided in every dark room.

In concluding the subject of windows, we may say a word on

the employment of ruby and other coloured papers and fabrics. These, as all know, rapidly bleach under the action of light, more especially the papers, and a single season will suffice to entirely discharge all the colour from such a screen as viewed from the outside. But it will be found that the inside, or side that has not been directly exposed to light, has changed but little, and, even viewed by transmitted light, the tint, though lighter than it was originally, has suffered less than might be expected. We advise, then, that the same side of the screen be invariably turned to the light, and then that will be the only side that will require renewing at intervals. The uniformity of illumination, as well as the "safety" of the light, will also be better preserved in this manner than if both sides of the screen are gradually bleaching simultaneously.

In our next article we shall deal with other appliances of the dark room.

ECONOMY IN THE DARK ROOM.

THE solution of "pyro," as made according to our instructions last week but one, will, as we stated, remain in good working order for a year or two, even if not specially cared for. But, as even acid solutions of pyrogallol are capable of absorbing oxygen, it is, of course, well to keep this mixture in properly stoppered or corked bottles, when it will keep for almost an indefinite time, with little discolouration. Many photographers prefer to keep it in corked bottles, to avoid the inconvenience of the stopper becoming fast, owing to the enclosed air parting with its oxygen, and so fastening the stopper by the double action of external pressure and the "locking" which is apt to follow that pressure. When a stopper becomes impacted in this manner, the best mode of loosening it—and it is surprising how difficult this sometimes becomes—is to give it a series of smart taps with some non-metallic object—a knife-haft for example.

We have, however, before pointed out that this may all be avoided by slightly greasing the stopper and neck with vaseline.

It is notorious that some brands of dry plates require a far stronger developing solution than others; and when any brands under consideration are considered of equal merit, it is obvious that, as this necessity makes an appreciable difference in the actual working cost, it affords data for deciding at once. Thus, let us take a half-plate size, that being more common than any. If we reckon, using fresh solution for each plate, that one brand requires a three-grain to the ounce, and another only one grain (and these are not extreme cases, though the average difference is as two to one), we have sixty grains needed for the latter, and one hundred and eighty for the former, if five ounces of solution per plate be used. Then, with pyro at 1s. an ounce, the working cost for this chemical alone is, per dozen, respectively, about 1½d. and 4½d.; in other words, 3d. per dozen. This is a point well worthy of looking into, for it means putting ten per cent. extra on the cost of an average cheap plate.

There is here another point to be noted as bearing on the economy of the use of pyro, especially to be considered at the present time of the year. It has been said that the temperature of the developer in dry-plate work has little effect on the rapidity of its action; but such a statement—at any rate, as regards dry plates as now made—is quite erroneous, as any one may discover for himself by a simple trial. Taking water as drawn from the main at the present season, its temperature will

probably be about 45° Fahr.; if, now, two solutions be made, one with water at this temperature, and another raised to about 75° by the addition of a little hot water, and a plate of equal exposure be placed in each, it will be found that the warmer solution will develop in almost half the time required by the cooler. When a number of plates are to be developed it will be seen that this difference represents a considerable amount where paid labour is involved, and, if the required speed is brought about by using stronger solutions, we get again that waste of money which it is the purpose of these articles to show how to prevent.

Passing from pyro to the other main constituent of the developer, there is little to say beyond repeating our frequent recommendation, that the solution be diluted with an equal quantity of water as soon as taken into stock, comparatively weak ammonia solution parting with the ammonia gas much less rapidly than the strongest. We have also recently pointed out that it is liable to absorb carbonic acid from the atmosphere, and so lose strength from another cause. To avoid this, the bottles should be kept well stoppered and, indeed, if any quantity be stored, the bottles not in actual use should always be luted at the stopper, which is easily done by applying a paste made by working linseed meal into a mass with water; this is most readily done in the palm of the hand.

Our remarks must now conclude by reference to what a well-known photographer terms the "painful" subject of waste plates. It goes without saying that, bearing in mind the strong feeling we have about the saving of "hypo" residues, we advise that all rejected plates, either accidentally damaged or found to be useless through moving of the subject, incorrect exposure, and so forth, should, before being cast aside, be passed through the fixing solution to dissolve every particle of silver possible to be saved along with the rest of the valuable contents of that liquid. Whether it is worth while collecting developed and fixed negatives for the sake of the silver they contain is a question whose solving depends upon the value of the labour employed. If the plates are cleaned solely to this end, we are afraid *le jeu ne vaut pas la chandelle*.

But what of the immense quantities of rejected negatives stored all over the country in the hands of amateur and professional alike? How are they to be utilised? How cleaned? As to their utilisation, where since wet plate for enlarging and such-like work is carried on they are very useful if of good quality glass—not by any means universally the case. But this would not utilise one per cent. of the waste negatives daily produced, and again the question thrusts itself into notice. Here we would appeal to our readers; our own practice is not extensive enough to supply a thoroughly practical answer. We can only describe one very admirable use that we know of their having been put to; that is, the glazing of greenhouses. We know of many houses so glazed; one successful amateur gardener having the whole of his houses roofed with rejected negatives, while another collected his 12 x 10 plates till he could make a window house of a few feet square; and this, as we need not say, would require several dozens. As to how to clean them for storage and future possible use, if these articles did not treat of "economy," we should be inclined to repeat the reply given to a similar query put at one of the photographic societies' meetings, "Clean them with a hammer!" Indeed, we are not very sure if, bearing in mind the worry and trouble of storing such heavy and lumbrous articles, this is not in the end really the most economical way of dealing with them after all. This, however, is debateable. For the rest,

we feel assured that if our advice is acted on it will really be followed by economy, both in the printing room and the dark room.

WE have now entered the month of November, and the photographic season of 1889 is now practically at an end. It is true that many amateurs will still be at work, obtaining autumnal and winter effects, and professional portraitists will be utilising the negatives taken during the summer for enlargements. But the busy time may now be said to be over. Upon inquiry amongst the profession generally, we are pleased to learn that they are to be congratulated on a prosperous year. Most of the leading houses, both in London and the provinces, say that the past has been the best season for business they have had for several years. Where this opinion has not been endorsed it has been by the middle-class photographers, and it is these who complain the most bitterly of the effect of amateur photography. The majority of those who supply apparatus also affirm that this has been the busiest year they have ever experienced. This is hardly to be wondered at when we note the large influx of new recruits there has been in the ranks of photography.

It will be remembered, on more than one occasion, we have advocated that in the new National Portrait Gallery a portion should be set apart for photographic portraits. We have also pointed out that the counterfeit presentments of many who have distinguished themselves in various ways would be lost to the nation for the simple reason that there may be no oil or water-colour paintings of them in existence, or if there is, their friends will not part with them. Or it may be, if there is a painting, that it may be of such a mediocre character that it could scarcely figure in a National collection; yet at the same time there might be photographs which are really works of art. We are pleased to see that our suggestions are being echoed by the general press. In a recent issue of the *Sunday Times* we find the ideas we expressed have been entirely reiterated. With a little persuasive agitation we are convinced that a photographic section in the new building will be secured. We commend the subject, once more, to the many amateur photographers now having seats in Parliament.

PHOTOGRAPHY is frequently utilised by the police in the shape of portraits of those "wanted," but it is somewhat of a novelty to see it used in connexion with those whom the authorities are desirous of getting quit of. Outside the police station in a suburban town we recently saw a cabinet portrait of a much better kind, by the way, than those usually issued by the police—a Woodburytype. It was the portrait of a pretty, chubby-faced, well-dressed child, about two years old. Together with the portrait was a full description of its wearing apparel, &c. The little one, it appears, was left surreptitiously in a garden, and the police authorities were anxious to learn to whom it belonged. No doubt photography will be, if it has not already been, the means of leading to the youngster's identification.

A SHORT time back we noticed in an auction room a number of expensive photographic mounts for portraits, those of the dark colour with bevelled and gilt edges. There was nothing unusual in such mounts being seen where miscellaneous scientific property is offered for sale; but in this instance they bore the names and addresses of some of the leading photographers in London and the provinces; and, in addition, some had on them the name of a very popular actress. One could but speculate as to why the mounts were there, seeing that the artists whose names they bore are all carrying on flourishing businesses, and the actress is still in the zenith of popularity. Presumably, any one purchasing these mounts would consider he had the right to use them, and the probabilities are certainly that no better pictures were likely to be put upon them than the general run of the work issued from the establishments they represented. The chances are, however, that they would be used for much inferior ones. In this event, as a matter of course, the work would be credited to the houses named on the mounts, hence their reputation would suffer. Again, any portrait of

a lady on the cards bearing the name of the actress might be mistaken for the latter by those who were not familiar with the parties. Fancy the feelings of a young and beautiful actress if she saw the portrait of an ancient dame bearing her name; or those of a first-class photographer on seeing third or fourth-rate work with his name and address on the mounts.

If the mounts were condemned from any cause—say because they would act injuriously on the pictures—one can scarcely imagine that the photographers would elect to dispose of them for the small sum they might be expected to realise at an auction sale; for it follows that, if the pictures eventually mounted upon them faded or became stained, the discredit would fall upon those whose names were on the cards, unless the circumstances were known, a thing hardly likely to be the case. Whether the mounts caused the pictures to fade, or inferior work was put upon them, in either case the reputation of the house whose address they bore would be placed in jeopardy. If the mounts were sent for sale without the cognisance of those whose names they bore, the proceeding was highly reprehensible.

A CORRESPONDENT, a retired portraitist, writing anent the leaderettes a fortnight ago—in which we mentioned that notwithstanding the great advancement in the art during the last twenty-five years, silver printing, as regards permanency, had retrograded—puts the somewhat pertinent question, “Has photography, from a technical point of view, really made any advance whatever? Has it not, like silver printing, also retrograded?” He says, in effect, that before the retouching of the negative was introduced, and when the operator had to make and keep in order the materials for preparing his plates instead of being supplied with them ready prepared, he had to rely solely upon the technical excellence of his work. If that were defective, either from the lighting of the model or from any other cause, there was no after remedy. Yet, at that period, work was produced which, in quality and size, was in no way inferior to that now made, notwithstanding that much of its merit is due to the retoucher's art. When, in the old days, a photograph was exhibited as “untouched,” it simply meant that the print had not been worked upon—sophistication of the negative being a thing unthought of. There is much in what our correspondent says, for there is no question that negatives are now passed in first-class establishments, because they can be improved by the retoucher, which in former times would not be tolerated for a moment.

THE writer of the communication just referred to makes a suggestion which is worthy of consideration. He says, “Why does not the Photographic Society of Great Britain, whose province it is to advance the art technically as well as artistically, offer a medal, or medals, for purely untouched work? Also others expressly for retouching, which may now be considered a distinct industry in photography; yet it has never been recognised as such by any Society.” In conclusion he adds, “The Photographic Society might well take a lesson from some of the City Guilds, who now offer annual prizes for the best technical work in the different crafts they represent.”

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

No. V.

J. P. Gibson (Nos. 205 to 208).—Four exceedingly well chosen pictorial scenes, which should all have made very good photographic results. No. 205 is the best of the series, arising from a lesser amount of those dark portions of foliage, which, if not properly attended to, completely neutralise the good that is elsewhere; and in three of these pictures this shortcoming has received its due reward, which is unsatisfactory, inasmuch as such charming subjects deserve better treatment.

H. B. Berkeley (No. 227 and eight other small pictures of scenes in Venice).—Nos. 228 and 230 are exceedingly well chosen for effect, where moveable objects (boats, &c.), have been selected at their best positions to assist the intended pictorial result; many of the others are very good, but those more particularly alluded to are most picturesque in character, and show taste and discrimination in selection; the whole have been also well treated photographically.

George Davison (Nos. 234 and three other frames).—Some exceedingly good examples of work, the negatives of which were made by a pinhole in place of a lens. These photographs are very interesting, as they afford evidence that foregrounds are sometimes overpowered with light when taken by a lens, which does not appear to be the result when taken with a pinhole; at the same time, it would seem that certain colours from dark-green foliage are just as difficult to be secured as they are by a lens. These examples of “natural” photography in its absolute rendering of facsimiles of nature, without suffering from any optical shortcomings, have a serious question to reply to: How came it to pass that the same clouds should be in two such different pictures as Nos. 10 and 237? The only difference being that their position is reversed, the points of view must, therefore, have been so far apart that some great natural problem has thus been brought forward for explanation.

Alexander Keighley (Nos. 263, 291, 292, 294).—These small photographs reveal the fact that the exhibitor possesses art capabilities which time will develop into some far more advanced productions. These pictures show much thought in the selection and treatment of the subjects, where figures have been arranged very nicely, so as to tell a tale, although simple in idea. No. 292 is the most ambitious; two boys, supposed to be “weary” and “with toil oppressed” (although they look very well fed), show much artistic feeling in their arrangement of position; whilst one of the boys makes a capital model for facial expression. The rest of the details have also been very carefully attended to. All these small studies give evidence that some most excellent work will be forthcoming from this very promising exhibitor.

Henry Stevens (No. 264 and six other similar pictures).—They are all exceedingly good specimens of photographic work. It is somewhat unfortunate that the models (apparently his own family), although very choice in dress and attention to orders, yet hardly justify some of the titles. This must arise from the studies being apparently only a reproduction of the ordinary every-day life of the models, without having been submitted to artistic control. They appear like very good portraits, but not pictures of events. The scientific aspect of this exhibitor's work is always so excellent, especially in his flower subjects, that we should be glad to give equal praise to the higher possibilities of the artistic faculty. The carefulness and skill shown in the use of the scientific portion of photographic picture making by this exhibitor should be carefully followed by many.

Miss Florence A. Harvey (Nos. 272, 277, 278).—Three very good studies of animals in motion—being stags and horses. These pictures show thought in the selection of a good arrangement of position at the moment of exposure, and hold out prospects of better work still in the future.

H. Bedford Lemere (No. 302), *Sandringham, Views of the Interior*.—These are very excellent specimens of this class of photographic work where great attention has to be given to the scientific side, and this has been done with most successful results. Great taste and skill have been shown in the choice of the point of view, as also in the arrangement of furniture—all these matters helping to make some good pictures.

Harry Symonds (No. 307), *Yacht Racing Scenes*.—In one frame are eight very effective photographs of yachts, where great attention has been given to effect by clouds being printed in, so as to aid the contrast of light and dark. There is only one matter which might be alluded to, and that is the effect produced by placing several pictures so close together; the difference in the sea lines has a retarding effect upon the vision to the detriment of the exhibits.

Thomas Fall (No. 309), *Dog*.—There are some other heads of dogs by this exhibitor in the Exhibition which are very good specimens of this class of work. They consist of vignettted heads only (thus eliminating a vast amount of study and awaiting good positions, which is a main point in animal pictures), and thereby affording possibilities of likeness, which apparently was the main point in view. They are very well done, as also has been the brush work, which has been used very effectively in completing the vignette form which these studies take.

Ralph W. Robinson (No. 314 and five other pictures, all about 15×12).—This series of photographs contains some very excellent work, in five of which country figures have been most skilfully

introduced, each telling a tale of human hope and joy. The sixth picture, perhaps, is the best. A group of oxen have arranged themselves in a line, which accords exceedingly well with the outline of the distant clump of trees, which are really far away, and thus a picture is the result. This style of photographing combinations of scenery with small figures will eventually be the peculiar outcome of this most prolific exhibitor.

F. W. Edwards (No. 322), *Woolpits*.—A country house, with grounds taken from an elevation, displaying a very effective bit of rising ground. The success of this work arises from the perfect way in which the lens has been utilised. Detail pervades the whole of the photograph, which is 23 x 16, which is also equally a very fine production taken direct, and is a remarkably fine specimen of scientific usage of materials, as also a well-chosen picture. No. 355, *Lambeth Palace*.—Another photograph the same size.

Miss E. Boyce Brown (No. 324), *Left Behind*.—This is a carbon enlargement from the original negative by the exhibitor, and in design is very good. A little boy being wheeled in a barrow has been suddenly left alone, and expresses fear at his position. This point has been seized upon by the exhibitor, and a picture produced of realism which is most effective. The colour of the print is rather warm, a cooler tone would have been more effective.

Hezekiel and Jacoby (Nos. 335, 336, and 337).—Three foreign portraits of ladies, noticeable from the fact that they are good specimens of the Pizzighelli printing process. In these photographs a very nice deep tone of colour has been produced.

Rev. H. B. Hare (No. 352).—A river scene, with bridge and distant dwellings, very carefully treated. There being no leaves upon the trees, that difficulty has not had to be battled with, the result being a very nice example of detail exceedingly well manipulated. This is really a very effective study, where two boys fishing (in the foreground) form some of the darkest portion of the design, which is thus made most effective.

Enrico Resta (No. 363), *Children's Portraits*.—Very pleasing and effective photographs are here before us, where all the positions seem very natural, yet at the same time this result has only been attained by very careful study in many of these fifty-three specimens. A very pleasing effect has been produced by using light backgrounds, which considerably help the pictorial result. Altogether these portraits are exceedingly good.

F. Whaley (No. 393), *A Mother's Pride*.—Now this is a picture which deserves some praise, for the model, who, from her expression, we assume to be the actual mother, has been very carefully and nicely posed; the play of light and shade, and the detail of the composition, have been very carefully studied, the result being a very interesting picture, and also an exceedingly good photograph. Only one matter we should like to notice: a piece of drapery rising just behind the mother up to the top of the picture, with dark broad lines on it, disturbs the repose, which otherwise is very nicely expressed. Altogether this picture reflects much credit on the exhibitor.

B. Scott & Son (No. 391), *Helena*.—This photograph is an attempt to produce a classical picture, the subject being a young female attired in a dress which is intended to be something approaching the old Greek costume. The result so far has been very good, for this dress is the most successful part of the picture, as it has been treated, scientifically, exceedingly well, the only part which does not quite realise the classical idea is the face of the model, which, however charming it may be, is not in general outline severe enough to pose for the subject, hence the picture assumes the character of a lady's portrait in classical costume.

R. Faulkner (No. 392), *Portraits of Children*.—The Exhibition without some specimens of this exhibitor's photographs of children would hardly be complete, so persistently year after year do they show themselves to please us by their refinement of treatment, both in arrangement of positions and in chemical manipulation, the result being a quiet appreciation of the art shown in their production.

T. Protheroe (No. 412).—A frame containing two studies which should never have been placed together, one subject being an old bellman, a *Bristol Fossil*, merely a facsimile of the individual; the other a well-arranged female, as *Marie Antoinette*, standing with hands clasped tightly together, with a nervous shrug of the arms, the head turned looking up at a crucifix on the wall. The face is well

suit for the character, and the expression has been carefully thought about, and yet there is something antagonistic to that appreciation which the study deserves. We arrive at the conviction that this must arise from the two sides of the figure and position of hands being almost exactly alike, and the picture thereby becomes automatic; very carefully thought over, very nicely photographed, but it hardly excites any sentiment of sympathy, this presentment being somewhat too mild in the expression of the figure.

Werner & Son (Nos. 434 and 445).—Two very large portraits taken direct, one a lady who, for the sake of her extreme length of costume, has been placed too much to the left side of the picture, which leaves her in a position to withdraw some day quite out of the frame. The detail of this light dress has been very carefully attended to, and is a very nice specimen of careful manipulation, but the face and hands of the sitter have suffered, so that in a large room this picture would partly lose its principal interest because the features retire and the costume asserts its reigning power. No. 445, *Prince Edward of Saxe-Weimar*, is quite another picture; here, despite the very light portions of some part of the costume (military), the face, having been carefully lighted, assumes its right function, viz., a likeness which demands the whole interest of the spectator, the result being a good and very perfect specimen of photographic portrait work.

THE APPARATUS.

We have already spoken of two cameras of foreign make which are contributed by Mr. Oscar Schölzig. We are now in a position to say more concerning them, and by the courtesy of the exhibitor to give illustrations. As stated last week, the principle involved is that of transferring the plates from a reservoir or plate box to the camera in which they are exposed. The inventor of this special appliance for effecting this transference is Herr Fichtner, its maker is R. Hüttig, of Dresden, and it is said to have been patented in "all countries." It is suitable for either dry plates, sensitised papers, or celluloid films. The mode of attaching the plate box to the camera is shown in Fig. 1. A firm clamping of one to the other is effected by a hook at

Fig. 1.

b (Fig. 2), connecting with a below, and by a turn-button, c, at top. To transfer the plate from the box to the camera, the lever, f, on

Fig. 2.

the top of the camera is pushed forward, which opens the passway from the box; next a bolt, g, on the handle of the slide, d, is pressed,

which causes a hook to pass into the box and grasp that plate which happens to be opposite the aperture. Fig. 3 shows the camera and plate box when turned from the vertical to the horizontal position, in

Fig. 3.

order to vary the form of the picture. In this case the dark shutter of the slide is pulled downwards.

We observe that the editors of several foreign journals, who are supposed to be more conversant with the working of this camera than we are, have pronounced it as excellent, and there seems no reason why we should not share in this opinion.

Ferrero's Film Carrier, which has already been alluded to, has never yet been described by us. By the aid of the adjoining cut

Fig. 4.

we shall now endeavour to do so. It is a dark slide and changing box combined for celluloid films. It enables the photographer to carry and to expose two or even three dozen films without having recourse to a dark room. It consists of a box, the front of which is fitted as a dark slide. Inside the box a loose board, actuated by a spring, presses the films towards the rebate, whilst a light *papier maché* board divides the film which is being exposed from the others, and a similar board placed behind the unexposed films divides them from those which have been exposed. When the film has to be changed, the opening of the lid causes the pressure board to be drawn back to the bottom of the box, thus leaving ample space in which the films can be changed. Attached to the carrier is a bag having two holes, in which the thumb and forefinger are inserted for changing the films. The two finger holes are provided with elastic bands, which exclude all light from the interior of the bag when the fingers are inserted.

The advantages claimed for this carrier are: 1. Extreme simplicity and absence of anything liable to get out of order. 2. The films are put into the carrier just as they are taken from the packet, no shields or metal frames being required. 3. The films are moved by the fingers; no reliance is placed on springs or the action of gravity, which so often fail to act in changing boxes for glass plates. 4. Two qualities of films can be carried in one carrier, and either can be picked out for exposure as required. 5. The operation of changing the films is done in a few seconds, whilst the filling or emptying of the carrier is infinitely more simple than with roller slides.

Mr. W. F. Stanley, Railway Approach, London Bridge, is the maker and exhibitor of this piece of apparatus.

LANTERN SLIDES ON GELATINE PLATES.

In giving a precise formula for the preparation of the emulsion, I do not pretend to offer the very best that can be devised, but merely one that, after trying many variations, seems to me to be the best for general purposes, combining as it does very excellent quality of results with the greatest ease, both in preparation and manipulation.

Opinions may differ on the subject of which haloids to employ, whether bromide of silver alone, or combined with iodide or chloride, or both. After trying almost every possible variation, I am convinced not only that the best combination is the bromo-iodide, but that the presence of iodide confers distinct advantages, both in colour-giving and other good qualities, and in rendering the general working of the emulsion easier and cleaner. I have used chloride, which in a negative emulsion plays an important and valuable part; but for positive purposes, unless worked in an entirely different manner to the ordinary plates, tends rather to lower the quality of image, especially in the matter of tone. I shall, therefore, confine myself to a bromo-iodide formula.

This may be stated as follows:—

A.	
Gelatine (soft)	100 grains.
" (hard)	60 "
Bromide of potassium	120 "
Iodide	6 "
Nitrate of ammonia	20 "
Water (distilled) as required.	

B.	
Alcohol (methylated)	1 ounce.
Nitrate of silver	150 grains.
Nitric acid, s.g. 1.420	1 minim.
Water (distilled)	2 ounces.

The choice of gelatines is, of course, one of some importance. For the softer kind I decidedly give the palm to the old favourite, Nelson's "No. 1 Photographic," which I consider unsurpassed by any I have used; indeed, except for its tendency to frill under slight provocation, I should confine myself entirely to that kind, using, say, 200 grains instead of having recourse to the hard. Another "soft" gelatine that answers nearly as well, if very carefully filtered, is a sample of sheet gelatine by the same makers, known, I believe, as "No. 1 Flake," and this has the advantage of being cheaper. The mixture, however, will give the better result, and the question arises which of the numerous "hard" samples in the market to select. If it were for negative purposes I should have no hesitation in recommending Nelson's "X Opaque," but after what I have said on the subject of absolute clearness of the film, I can scarcely do so. Of the foreign kinds which are clearer and possess less colour I should prefer Coignet's if I could always depend upon getting it free from grease spots, which, I am sorry to say, is far from being the case; otherwise, it is a pattern gelatine, both for hardness, setting qualities, and absolute transparency. Next, I rank Heinrich's, and though this varies much in different samples, it is perhaps, generally, more reliable; and after that, again, Simeons's may be used.

Let the gelatine be weighed out and placed to soak for a few minutes in boiled and cooled rain water, and when soft, let it be vigorously rubbed together, as described in my last article (page 632), to loosen and detach any particles of dirt or foreign matter from the surface. After this treatment, rinse it well; squeeze out as much as possible of the water, and place it to soak in distilled water for a couple of hours at least, or until thoroughly swelled. Now take it out of the water, drain it for a minute or two, and then liquefy by heat and make the quantity up to four or five ounces with distilled water. Heat the solution to 150° or 160° Fahr., and filter, as already described, in front of a clear fire. Or the gelatine may be liquefied without the addition of further water, when it will filter with perfect ease, though, perhaps, more slowly; and the filter may then be washed out by passing through it three or four times sufficient hot distilled water to make up the volume of the gelatine solution to four or five ounces.

The bromide of potassium and nitrate of ammonia are next added in crystals and stirred until dissolved, the iodide being reserved for addition at a later stage. I am unable to explain the precise

function of the nitrate of ammonia, but I have used it for some years and find that it makes an emulsion, whether for negative or positive purposes, much cleaner than it would otherwise be, possibly from its solvent action on some of the organic compounds of silver that tend to produce fog. It only now remains to keep the mixture hot, or even to raise it to 180° , while the silver solution is being got ready for sensitising.

Dissolve the silver in the stated quantity of distilled water, and add the nitric acid, and finally the alcohol. The acid is best added in the dilute form (say 1 : 20) as securing greater accuracy, which is important, as if too much be used, not only will great insensitiveness be the result, but the gelatine will be softened or decomposed. The alcohol is added, on the recommendation of a very early writer on gelatine emulsion, to promote fineness of division—a function which it undoubtedly performs.

Everything up to the present may be performed in full daylight if desired, but the subsequent operations must be carried on in the dark room. The two solutions of bromised gelatine and nitrate of silver, both at a temperature of 180° or thereabouts, are therefore taken into the dark room and carefully mixed by pouring the silver into the gelatine a few drops at a time, or in a very slow continuous stream, the mixture being all the while vigorously whisked with a silver fork or wooden salad server, or any similar instrument that will not be acted upon by the emulsion. Under ordinary circumstances, the quality of the emulsion, so far, at any rate, as fineness of division of the bromide is concerned, depends greatly upon the care with which the mixing is performed; but here, in the presence of so large a quantity of gelatine, it is scarcely a matter of serious moment whether the whole of the silver is thrown in at once or half an hour is consumed in the process. It is better, however, to err on the right side and be careful.

After mixing comes the process of digestion, or "cooking," by which the sensitiveness of the preparation is brought to the right pitch, and this constitutes in ordinary or rapid emulsion making the crucial part of the task. In the circumstances under which we are working, however, the difficulty is practically nil, as our aim is not to attain to anything but a moderate degree of rapidity, as compared with quick commercial plates. It suffices, therefore, to keep the emulsion at the mixing temperature—about 180° —for an hour or so, which is easily managed by means of changes of hot water, into which the jar or bottle containing the emulsion is plunged. A longer immersion or a higher temperature will do no harm; but those I have given will serve all our present purpose.

Those who are not in the habit of making emulsion—and it is for those I am chiefly writing—will probably imagine countless difficulties and inconveniences in this part of the proceedings, but with a little method all trouble will disappear. The first important point is the mixing vessel, which must, obviously, be one that will stand a considerable degree of heat. Ordinary glass bottles are not, as a rule, calculated to bear the strain put upon them, unless specially "tempered" for the purpose. A wide-mouthed earthenware or china jar answers better, and if thick enough to be thoroughly impervious to light, it is an additional advantage. A very useful article for the purpose that I have used for small quantities of emulsion for some years past consists of a well-glazed earthenware shouldered jar with solid cork-fitted stopper of the same material, pierced with two holes, through which glass tubes can be passed. This constitutes the principal item in an inhaling apparatus, and as the makers are in no way connected with photography, there can be no harm in advertising them in these pages, namely, Messrs. Bourne, Johnson, & Latimer, of 35, Castle-street, Holborn.

With this or a similar apparatus, if the projecting glass tubes be covered with short pieces of rubber tubing pushed well down to the stopper, the emulsion is perfectly protected from light, although there is free vent for steam to escape. Consequently, after mixing, if the stopper be inserted, the jar and its contents may be taken with impunity into open daylight or gaslight and set to digest in a saucepan of hot water beside an ordinary fire. Or, failing the "inhaler," an ordinary preserve jar may be placed within a tin canister of suitable dimensions, and containing a little water, and with the lid on, the light will be similarly shut out, though there is free escape for steam, even if the whole affair be boiled. Perhaps many similar contrivances will suggest themselves to individual readers.

I have spoken of continuing the digestion for an hour; but up to the present it will be noted that the emulsion is one of plain bromide, the iodide not yet having been used. Consequently, when the digestion has gone on for half an hour the jar is opened, in the dark room of course, and the six grains of iodide of potassium, in crystals, thrown in. After two or three minutes stirring, to effect the solution and thorough incorporation of the iodide, the jar is recorked and set to finish its term of "cooking." This method of introducing the iodide is recommended as tending to bring about a finer state of division than if it were added at first with the bromide, as the iodide in combining directly with the silver does so in comparatively coarse particles, whereas by the method given it acts upon the fine particles of bromide of silver already formed, converting them into iodide.

The next operations—those of "setting" and washing the emulsion to free it from the soluble matters it contains—are usually ranked as the most tedious and troublesome; but I shall endeavour to show how they can be conducted with the least possible inconvenience or danger of failure. After cooking, the emulsion is poured into a flat dish or shallow basin to set, or become solid. In ordinary practice it is customary to resort to the use of ice, especially in warm weather, in order to get the "jelly" into a sufficiently firm condition to bear the subsequent washing without loss of material, and without absorbing too much water. My method, however, renders ice entirely unnecessary, and, in fact, renders us almost independent of the setting of the emulsion, whether it be firm or the reverse.

When the emulsion has become solid and feels tolerably firm to the finger—a condition it will attain in an hour or two if the dish or basin containing it be set in or floated on the coldest water obtainable—it is ready to commence washing. For this purpose I pour on to the emulsion, without disturbing it in its dish, sufficient good, clean methylated spirit to well cover it. When this has stood upon it for five minutes or so, I "score" the mass of gelatine in all directions with a strip of glass or bone spoon to permit the alcohol to penetrate freely into the mass. In a few minutes more I scrape it well away from the dish, stirring it well up with the alcohol, and adding more of the latter, if needful, to cover it.

By this use of the alcohol, instead of water, the jelly is rendered firmer and more manageable, however "soft" it may be originally, in consequence of the extraction of a portion of its water by the alcohol, which also exerts an independent toughening action of its own. At the same time, the water in leaving the gelatine to combine with the alcohol takes with it a great portion of the soluble salts, and more of the latter follow by natural diffusion during the subsequent soaking.

When quite firm to the touch, a small quantity of distilled water is added, say about as much as the alcohol already used, and the mass left to soak for about half an hour with an occasional stir. The dilute alcohol is then poured off and distilled water substituted, and the latter is poured away and renewed at intervals until the emulsion has ceased to show any signs of the presence of alcohol, beyond a faint smell, which it always retains. The absence of "greasiness" on adding fresh water is the sign of the removal of the spirit. If two or three changes of distilled water be given after this point is reached, it may safely be considered that all the soluble salts have been eliminated.

I claim for this process the advantages of simplicity as well as economy, bearing in view the conditions I have laid down as to avoiding the introduction or precipitation of insoluble lime salts in the emulsion. To thoroughly wash in the ordinary manner with distilled water would necessitate the use of a very large quantity of the latter, which, at sixpence a gallon, even if obtainable, would add very materially to the cost of the emulsion. But for the above quantity of emulsion an equal volume of spirit is more than ample, and with methylated spirit at from three shillings to three and sixpence a gallon, the extra expense for alcohol is not great; while the quantity of distilled water required to finish off need not exceed half a gallon if judiciously used. I have thoroughly freed ten ounces of emulsion from soluble matter in this manner with only one quart of water. I venture to think also that the elimination of the salts is more perfectly attained by this plan than is ever the case with plain water, unless the washing be continued for an injuriously protracted period. Certainly it is far better attained than is otherwise possible with the same amount of trouble or in the same time.

The emulsion is now ready to be melted up for use, or arrangements may be made for its preservation. These usually consist in drying it—a tedious, troublesome, and never entirely satisfactory job. I dispense with that operation by well draining the lumps of jelly, transferring them to a clean bottle, and pouring over the mass sufficient to cover it of methylated alcohol, containing a quarter of a grain of salicylic acid to each ounce. In this state the emulsion will keep perfectly for a very long time; but if it is required to keep “indefinitely” it will be well to pour off the first lot of alcohol after a few days and replace it with a fresh supply, also containing salicylic acid. By this means much of the water will be removed and the chances of decomposition correspondingly lessened.

It will be, of course, necessary to bottle off in this manner known quantities of the emulsion, as in the moist condition it is obviously impossible to weigh it, and its subsequent use would therefore be based mainly on guess work. But if it be bottled in batches as made no trouble will arise, and a stock may be prepared during slack periods for use at busier times. When this preserved emulsion is required for use it is necessary some hours previously to pour off the alcohol and replace it with distilled water, changing this two or three times and using just enough to cover the mass of emulsion. This removes the greater part of the alcohol and restores the emulsion to its former “swelled” condition and facilitates its solution.

In another article I hope to describe the remaining part of the process, and also the method of coating plates, with a few simple aids that will be useful to the amateur.

C. BECKETT LLOYD.

THE NEGATIVE IMAGE.

NO. II.

THE following occurs in the address of the President of Section A at the recent British Association meeting: “The question as to what is the exact product of the decomposition of a silver salt by the action of light is one which has not as yet been fully answered.” This is an emanation from the originator of the celebrated theory of the sub-haloids, which has received considerable support for years.

In the same address, what is virtually a doubt is cast upon the conclusions drawn by Mr. Carey Lea from the series of beautiful experiments on the silver salts, an account of which that distinguished writer published in the summer of 1887, and which was reproduced in these pages at the time. Reference to the first of the memoirs—that treating of the coloured haloids in relation to heliochromy—will show that Mr. Lea takes occasion not merely to reiterate his doubt of the correctness of the sub-haloid theory, but to instance certain formidable facts inimical thereto, namely, the comparative action of nitric acid upon sub-salt and photo-salt. We therefore find the two gentlemen, whose researches into the chemistry of photography entitles their remarks to general attention, acutely sceptical of each other's deductions, while one of them practically confesses that he regards his own with some misgiving. Nevertheless, these important disagreements over “what is the exact product of the decomposition of a silver salt by the action of light” are not unprofitable in this sense—they form an ark of refuge for many who, when studying the properties of those interesting compounds, are led to form opinions at variance with the older beliefs which, in the absence of a general acceptance, they have less compunction in treating with discourtesy.

Probably in very recent times no memoir on the silver salts is so replete with succinctly argued photo-chemical philosophy as the third of the series by Mr. Lea, identifying the photo-salts with the material of the latent image. The facts there arrayed on behalf of the author's theory have a weight and a completeness about them that are not characteristic of the evidence advanced for its sub-salt and vibration rivals.

The memoir in question is largely concerned with the action of sodium hypophosphite upon sensitive haloid, by which means the experimentalist identified the chemically prepared photo-salt with the material of the undeveloped impression. Upon normal silver bromide the effects of light and of hypophosphite, determined by subsequent treatment with developing agents, were demonstrated to be interchangeable. In Mr. Lea's own words: “In the entire absence of light sodium hypophosphite is able to effect a sensitive film of silver haloid exactly in the same way as does light, producing a result equivalent to a latent image formed by light and capable of development in the same way as an actual impression of light;” and “that these two effects . . . comport themselves to re-agents exactly the same way and seem every way identical.” What follows is, it must be allowed,

strongly corroborative of the primary resemblance, and is by far the ablest attempt to solve a long-standing problem in a thoroughly skilled and scientific manner.

The darkening of normal silver bromide in the camera and in unrestrained light, to which allusion has been made, long ago led the writer to consider whether a modification of the sensitive haloid would exhibit an acceleration of the direct action of light in such a degree as to place the property upon a serviceable basis. The remarkable influence of the alkaline hypophosphite upon the sensitive body, as recorded by Mr. Lea, also gave rise to the further speculation that the substance so formed was directly altered by the brief impact of light. Prepared films treated with sodium hypophosphite solutions of various strengths did not, however, yield results of a conclusive description.

But the previous suggestion that the darkening of normal silver bromide is the effect of the action of light upon the invisible body first formed by short exposure nearly concerns the belief in the possible existence of several true compounds of silver and bromine. For if the base took up the halogen in differing proportions, and the combining weight of the latter had a closer assimilation to that of chlorine than to that of iodine, we might further conjecture that the lower compound or compounds would be less stable under light than the higher, and consequently the more easily reduced and separated, at no loss of sensitiveness, but, possibly, on the other hand, with the added property of visible alteration. Silver is the only important metal classed as monad, and the sub-salt and photo-salt theories are incompatible with such an atomicity. If we conceived of that element being hexad or pentad, uniting with four or five parts of bromine, the equivalency of which was represented by 20 or 16, one-fourth or fifth of that now universally assigned to it, we should probably find that $\text{light} + \text{Ag}^{100} \text{Br}_4$ (188) = $\text{Ag}^{\text{Br}} \text{Br}_2$ (148); that $\text{Ag}^{\text{Br}} \text{Br} + \text{Light} = \text{Ag} + \text{Br}$; or that from $\text{Ag}^{100} \text{Br}_5$ we were enabled by the same agency to get respectively $\text{Ag}^{\text{Br}} \text{Br}_3 + \text{Ag}^{\text{Br}} \text{Br} + \text{Ag}$ and Br ; in other words, assuming such an atomicity and equivalency of the elements capable of being proved, and their various compounds to possess an amenability to the direct influence of light inversely proportionate to the weight of halogen in the combination, the final product of the two equations would represent deposited silver to form the image. It is almost certain that some such reaction as this is necessary to get visible camera negatives with short exposures; and although the assumption and that which immediately precedes it are still “of the clouds,” their aerial features are lessened if they be placed in juxtaposition with the teaching of the chemical text books, to which the behaviour of silver bromide, as we know it now, is in contradiction. Moreover, the extreme reducing power of light above conceived of is already clearly exemplified in the instances of the platonic haloids, which, if exposed to light on paper, are converted to platinous salts, while these again undergo further reduction, the metal and the halogen entirely separating.

In short, to obtain visible negative effects on normal silver bromide, the chief obstacle to success is that that body is not to be reduced to metal by light. Sensitive films allowed to remain in the light for days will only yield up an infinitesimal proportion of the metal in combination. Therefore, the ideal darkening in the camera is really convertible language signifying a total reduction by light of the sensitive haloid. While there is no ground at all for supposing that the addition of any substance with which we are acquainted to silver bromide in emulsion would operate as an instant reducer of the altered salt, there is considerable likelihood of the prepared film, under suitable treatment, giving such results as to justify the hope of further achievements.

Light has never been set to commence its work where now it leaves off, namely, upon what we will term a proto-salt, represented by the convenient formula, $\text{Ag}_2 \text{Br}$. Since, however, it was stated by Mr. Carey Lea that the photo-salts identical with the material of the latent image are themselves possessed of great sensitiveness to light (“if rose-coloured photo-bromide, and some normal bromides are exposed side by side, the normal bromide darkens but very slowly, while the photo-bromide is quickly acted upon”), it may be reasoned that the elimination of a portion of the halogen of a normal silver bromide plate would partly, and in an analogous sense, submit Mr. Lea's theory to practical proof, and perhaps afford a key to the elucidation of other and cognate matters now obscured.

It was formerly established by Vogel that silver iodide, when in contact with, among other substances, mercurous nitrate, stannous chloride, sodium sulphite, sodium nitrate, rapidly blackens in the light. These bodies, to which he aptly applied the term “sensitiser,” have great affinity for iodine, and, in some degree, for the co-relative halogens. Another term applied to them is that of “absorbent;” but if many of the re-actions in which some of the compounds play a part are studied there is some inducement to regard the word “absorbent” as a misnomer.

THOMAS BEDDING.

THE WHOLE DUTY OF THE PHOTOGRAPHER. No. IV.

Trees and ferns when they can be found motionless are always excellent subjects for the camera, but, best of all, when they can be found reflected in still water. Their beauty depends much on their fineness and complexity of detail, and in rendering this the brush and pencil need not seek to rival the camera. Rocks are also a very suitable subject, and they are patient and stay still where nature placed them. I think that a really good photograph of rocks is, in some respects, equal to the best picture that can be made of them. Let every one attend to his business; the artists may well leave the rocks to the photographer; they still retain much within their monopoly.

Photographs of mountains have been well abused for giving no idea of their height; and not altogether without justice, for I have seen a view in which the Matterhorn appeared like a mere pimple on the horizon. Now, from no point of view is the Matterhorn less than grand and terrible; and a picture reflects something of the artist's imaginative conception of its terrors, and so conveys a truer idea than the photograph, although the latter is correct, and the former represents the mountain as being about eight times its true height. I said not altogether without justice, because the opinion in its crude form usually refers to a taste degraded by the ridiculous exaggerations of the ordinary painter of mountains. I believe that in time the photographer may teach this person to mend his manners and educate the public taste to value correct representations of mountains.

Many of the worst æsthetic faults of photographs depend on their being made on the same principle as that celebrated picture belonging to the Vicar of Wakefield, where the artist was to paint as many sheep as he could put in without extra charge. That is to say, the purchaser must have good value for his money, and have plenty of things in one photograph; so we get atrocious products, including an angle of view up to a right-angle, whereas, *ceteris paribus*, the smaller the angle of view, the more nearly will the result approach to what may be seen by the eye at one time, and the higher will be the æsthetic value of the picture. This is a point which cannot be too strongly insisted on; the wide-angle lens may have its uses when we want small panoramas, but it can never produce a beautiful picture. When this is wanted the right thing to use is one of the lenses of a long-focus doublet. I know that many of the cameras of this day will not take such a lens; more's the pity! They will have to be made longer.

I see no reason why the photographic portrait should not rival the work of the brush in all the qualities most valued in a portrait. As a matter of fact it does not, but the reason I take to lie chiefly in the abuse of retouching. This craft, which ought to be an art, like making composites, or printing in sky, or any of the many tricks of the trade, is of great value in its proper place. Unfortunately, there is no agreement as to the proper place for the retoucher, and I would rather see the creature abolished entirely than let him continue his present work of destruction. There are many real defects inherent in photographs of human beings, such as the exaggeration of scarcely perceptible spots on the face till they appear like the marks of small-pox. In clearing away such offensive marks, and otherwise making the portrait more like nature than it could be without such aid, the retoucher is doing a useful work. In order to know just where to stop in this improvement, the person intrusted with the business ought to be an artist, and not a mere user of the pencil, and, farther, ought always to see the subject of the portrait, so as to be more sure to destroy none of the characteristic lines of the face. Really good large portraits are one of the rarest things in the world, but they might become common enough if the retoucher could be kept in order. Probably the reason why the best work, both in portraiture and landscape, is produced by amateurs is that they (the amateurs) are often unable to retouch, a fact for which I believe that they are not duly thankful. Far be it from me to assert that the products of the average amateur approach at all near to those of the average professional, but I do distinctly maintain that the very highest work in all departments is done by amateurs (that of the unapproachable Rejlander alone excepted; he, in truth, seemed to possess the merits of both classes).

I suppose that Rejlander must remain still for long entirely without rival, the king of photographers; but I say it is to the shame of the present generation that with all the advantages placed in their hands by science and mechanics they have not among them one such artist. It may be that even the name of Rejlander may be strange to some of this day, but if they could see some of his portraits they would go and hide their diminished heads in shame and wonder.

I believe that when Rejlander was about to take a portrait it was his practice to invite his sitter to breakfast and study his gesture and

expression while at ease and unconscious, and afterwards proceed to arrangement and lighting with great deliberation. How different from the practice of the modern fashionable photographer, who knocks off sitter after sitter during all the hours of daylight! In truth, considering the system by which they are produced, I marvel that his results are not worse. By the way, I wonder what has become of Rejlander's negatives; all his photographs that I have seen were beginning to fade.

A department of portraiture which receives far less attention than it deserves is one to which I have already referred briefly—the photography of men and women at work. In this subject there lies an inexhaustible supply of material for real pictures. The difficulties, it must be admitted, are not few; workmen are often enclosed in ill-lighted workshops, or in places where there is no room for a camera, and the photographer must go to them; he cannot bring them into his studio and expect to get them posed there in really natural attitudes. The position assumed by men and women in the performance of any manual labour which they can do well is nearly always beautiful and full of the grace of strength and simplicity. Walt Whitman knew this well when he wrote "The Song of the Broad Axe."

Now, I have said over and over again that a photographer must, before everything else, be an artist; secondly, he must be something of a scientist, but that he may certainly acquire by taking thought. But suppose one to say, "I am not an artist, but I want to make photographs." Like *Punch*, I would say, "Don't!" but if he needs must, these is still hope for him of attaining to a fairly high level, although not the highest.

It is said that the artist must be born, which is a common fate, and not made, which is false; for, like other men, he must submit to both of these processes of nature. The photographer who wishes sincerely to improve his work must seek to do so by first improving himself, which is by no means impossible. To begin with, he must not imagine that he will gain anything but woeful confusion by studying the productions of those who have written on "art in photography;" and he need not expect to get much from any writings whatsoever, except in so far as they may induce him to look to the right models for the training of eye and sense.

To become an artist a man must discover what is beautiful, and study it patiently and lovingly for his whole life long. Let him read Ruskin, and go to the Turner pictures in the National Gallery, not once, but many times, until he feels that he could spend the rest of his life contentedly in contemplating one of those miracles of man's handiwork. Let him read Ruskin or not, as he thinks fit, and go out into the fields and woods and use his eyes and leave his camera at home, for it may sound paradoxical, but it is nevertheless true, that by so doing he will in the end produce better pictures. There are fewer rarer qualities than a sense of colour; women have it a little more often than men, but even in them it is usually weak. The photographer working in monochrome is more likely than other men to lose or never to acquire an appreciation of colour, so I would say that whatever else he does or neglects he should study colour, for there is no doubt that the more he can appreciate one phase of beauty the better will be his knowledge of all others.

I look forward to the time when the photographers' rooms will be decorated with paintings glowing with rich colour, and the artists' studios with photographs.

COSMO I. BURTON.

EIKONOGEN.

THIS new developing agent has certainly come to stay, at least until something better is discovered. The rapidity with which it works, the clear black and white negatives that are so readily obtained with it, reminds the worker of collodion days and the iron developer. There is perhaps a little more care needed in judging of time in the longer exposures where small diaphragms are used in the lens; but for instantaneous work with large openings in the lens, eikonogen works with all the vigour of pyrogallol, and will give more detail in negatives of the same exposure than when using pyrogallol, without the risk of staining or fogging the negative.

Dr. J. Sehnass, in *Photographisches Archiv*, speaks thus of his recent experiments with the new developing agent:—

"For the past six months I have worked only with hydroquinone. The action and formulæ for this developer are closely analogous to eikonogen, it is therefore not very difficult to become acquainted with the latter.

"Experience shows in both cases that fresh solutions are only useful for the development of instantaneous views, whereas time exposures should have an addition of bromide of potassium, or, better still, should be developed with partly old developer. It may also be stated for

both developers, that carbonate of potassium develops quicker than carbonate of soda, but at the same time it has also a greater tendency to frilling. Under these circumstances an alum bath would be advisable in both cases.

"Preliminary baths have been used very seldom for hydroquinone, which is certainly a good thing in its favour; these are recommended, more for oxalate and lately for eikonogen, to help under-exposures, particularly in instantaneous pictures.

"In the rapidity of development of the latent picture, with equal strength and the same age of the solutions—whether fresh or already used—and equal quantities of the same carbonated alkali, I have observed no difference with equal duration of exposure on the same kind of plate. But in the strength of the negative there is an essential difference in favour of the hydroquinone. The latter develops undoubtedly much more powerfully, while the eikonogen produces less depth, but better half-shadows. The latter is therefore better for portraiture, while the hydroquinone is more suitable for landscapes and reproductions. The formula for mixing the eikonogen solutions, as published in the prospectus by the manufacturer, has given the best results, while the prescription of E. Vogel, published in the last number of the *Archiv*, recommending only half the quantity of eikonogen and more alkali (carbonate of potassium) gave flat, much too weak, negatives, requiring always strengthening.

"Plates developed with eikonogen, even if applied in extra strong solution, require, with the exception of the instantaneous negatives, almost always intensifying, at least for albumen prints."

What Dr. Schnauss says about the details in the half tones we have confirmed by our own experiments; but we cannot agree with him about hydroquinone being better for landscape work. With reasonably good judgment of the light, negatives of the highest character can be obtained with eikonogen, and in every respect equal to hydroquinone. There is also the added advantage that eikonogen works much more rapidly than hydroquinone. We have developed a number of negatives with eikonogen and have never found it necessary to intensify them, unless the eikonogen solution was too weak. Here also we may remark that weak solutions with much alkali have a tendency to fog. The negatives from weak eikonogen developer were flat and without density, thus confirming what Dr. Schnauss says about the use of more alkali and less eikonogen.

It is probable that eikonogen will be cheaper, like all other new developing agents, as economy in its manufacture is attained; but when we take into consideration its rapidity of action compared with hydroquinone, and its freedom from the foggy and staining qualities of pyrogallol, it seems destined to be a very decided improvement in developing agents.

—*Anthony's Photographic Bulletin.*

Foreign Notes and News.

THE expanse of land and sea which separates the two countries does not prevent a sociable exchange of amenities from taking place between Switzerland and the United States. An arrangement, namely, has been entered into by the three Swiss photographic societies and the New York Society of Amateur Photographers, by which the former will combine and send to the latter once a year a hundred slides of Alpine scenery in exchange for a similar number of selected American landscapes.

A LARGE panoramic orthochromatic photograph of the neighbourhood of Geneva, including the view of the Salève and the Alps, 50×60, has recently been taken by the Messrs. Charnaux Brothers. Our contemporary, the *Revue Suisse*, pronounces it a perfect tableau. Should the united societies place this among their first consignment the result will probably be to stimulate still further—if any stimulation is needed—the almost feverish activity of the American amateurs. We may be quite sure they will not rest till the compliment is returned in quality as well as kind, for the Americans do not like any one "to hold over them."

AMONG the more interesting exhibits of the Berlin Jubilee Exhibition appear to have been those comprised under the heading of Astro-Photography; and among these the admirable results obtained by Herr Eugen von Gothard (Herény in Hungary) seem to have been especially deserving of the highest commendation. This astronomer worked with orthochromatic plates and a ten and a quarter inch reflector, thus proceeding in the direction indicated some time ago by Professor Piazzi Smyth in the columns of this JOURNAL as the one most likely to be attended by success. Some of the results were obtained with an exposure of three hours and twenty-five minutes; a fact which, of itself, is sufficient to indicate the progress recently made in sidereal photography, for it is not long since it was thought a triumph of practical skill to succeed in keeping a telescope pointed to the same part of the heavens for over two hours

with sufficient accuracy. But the principal point is the success in photography by means of a reflector, and the fact that the results obtained with so small an instrument are nowise inferior to those of the Brothers Henry, obtained with their big reflector, but even show stars which do not appear on their charts. An additional point of interest is to be found in the fact that where the plates were exposed longer than necessary the image of the star on enlargement appeared with six rays.

HERR C. FABRICIUS, of Vienna, has constructed a ligroine gas lamp, which produces a hot colourless flame, especially applicable for the Aner light. The apparatus consists of a reservoir for the ligroine—a kind of essence of petroleum—which is sucked up by an asbestos wick, and conducted into a metal tube heated by a spirit lamp. A gas is thus formed causing a certain amount of pressure, and, mixing with air entering by lateral openings in the side of the tube, burns with a very hot, pale blue flame. The light is said to be of great whiteness, and, thanks to its richness in blue and violet rays, possesses a photographic power far superior to that of ordinary lamps.

It is amusing to read, in this year of grace and supposed general distribution of scientific knowledge, of the alleged discovery in Sweden of a new optical glass, whose wonderful qualities enable it to increase the power of microscopes and telescopes to a miraculous degree. Miraculous truly! for the glass in question is stated to have a refractive index 500 times that of ordinary glass. In addition to this it is said to be achromatic! These entertaining statements have been made, by the way, not in the *Timbuctoo Courier* or the *Central African Advertiser*, but in some of the daily papers of enlightened Germany!

ANOTHER of those picturesque differences of opinion of which the Fatherland appears so prolific, and which, at one time, seemed about to render the Berlin Jubilee Exhibition a fiasco, has recently been convulsing the interior economy of the Photographic Union of Berlin. Dr. Stolze, the President of that Society, has hitherto figured as the editor of the *Photographisches Wochenblatt*. It appears that he was recently served with notice to quit, but some formalities having been neglected in the appointment of his successor, Dr. Miethe, a controversy of a rather bitter and personal nature took place between the supporters of both gentlemen. The result was that the last meeting of the above-mentioned Society was much more interesting from the point of view of the psychologist than from that of the photographer. What the bone of contention exactly was it is very hard to make out; that there was a bone of contention, alas! is only too apparent.

AT the last meeting of the Zurich Photographic Club, Herr Bretsches exhibited a number of Alpine views by Herr Rzewnski of Davos, as well as several negatives on eosine-silver plates. Herr Schultheiss showed an ordinary plate, one half of which was exposed in the usual way, the other half behind a yellow disc. This latter showed a much greater amount of detail, but those present were not agreed as to whether this fact was due to the yellow disc or to the more lengthened exposure. Some interesting exhibits were also shown by Herr Böhni.

Our Editorial Table.

DIE PHOTOGRAPHIE MIT BROMSILBER-GELATINE UND CHLORSILBER-GELATINE.

VON PROFESSOR DR. JOSEF MARIA EDER. Halle a. S.; WILHELM KNAPP.

LEHRBUCH DER PHOTOGRAPHISCHEN CHEMIE UND PHOTOCHEMIE.

VON ALEXANDER LAINER. Halle a. S.; WILHELM KNAPP.

WE shall here merely acknowledge the receipt of these two excellent works, the former of which, containing 476 pages and 206 illustrations, is the fourth edition of Dr. Eder's valuable work; and the latter, a seemingly exhaustive treatise on photo-chemistry, of 260 pages, deferring till a near future a full notice of them.

PHOTOGRAPHS OF THE RED END OF THE SOLAR SPECTRUM.

By F. McLEAN, M.A., F.R.A.S.

THIS pamphlet, reprinted from the *Monthly Notices* of the Royal Astronomical Society, contains a page illustration showing the A group of the solar spectrum, from the photographs by the author, enlarged about eight and a half times.

SUN ARTISTS. No. 1.

LONDON: KEGAN PAUL, TRENCH, & CO.

THIS is the first number of an illustrated monthly work which has for its *raison d'être* the emphasising the artistic claims of photography by reproducing the best work of the best photographers in the best possible manner.

The projectors have acted most wisely in the selection of the artist by whose works this number is illustrated. Mr. Joseph Gale ranks, and for many years has ranked, among the very foremost of those whose artistic taste and manipulative skill have conducted to elevate photographs from scientific facsimiles of nature into the realm of art.

There are four of Mr. Gale's works in the number before us, respectively his *Sleepy Hollow*, *A Foggy Day on the Thames*, *Brixham Trawlers*, and *Homewards from Plough*. These are all executed by the photogravure process employed by the Typographic Etching Company, and all hand work upon the plates has been scrupulously avoided. This is well, at any rate in the present instance, for we cannot conceive of any work of even the most skilled engraver which if put upon the etching of *Sleepy Hollow* could improve it in the slightest degree. The text matter is of the most racy character, and is from the pen of Mr. George Davison.

Sun Artists is sure to take well, for never before has such an admirable five shillings-worth been offered to the public. It is of large size, and well printed on fine hand-made paper.

THE TERPUSCOPE.

UNDER this name Mr. Alfred Wrench, of the firm of John Wrench & Son, the well-known lantern manufacturers, has just completed the invention of an optical lantern so different in construction from all others as to merit special notice. As will be seen from the engraving,

it is rather taller than a single lantern of the ordinary form. It has a square recess, with grooved side guides in front and immediately below the condenser. When a slide is inserted, the screen now being quite dark, this is what takes place:—Upon giving one turn to the winch handle, which is seen projecting at the left side, an opaque curtain which obscured the disc rises and reveals the slide now projected on the screen; and after time has been allowed for its examination, during which the second slide of the series is inserted in the same manner as was the first, the handle is again turned, causing the curtain to descend for an instant and immediately to rise again, showing the second picture standing motionless upon the screen. The slide which was first seen is now standing in a groove above the optical system ready to be lifted out, and the action described goes on automatically all through the series. This system entails all the slides being of uniform size and unmounted; but so well has every provision been anticipated, that at any stage a mechanical or other slide mounted in wood can be inserted, *in situ*, without this being discovered by the spectators and withdrawn again; or the rolling curtain effect may be temporarily or altogether suspended, the lantern then becoming, for the time, one of the ordinary class.

The inventor claims that one great advantage of this rolling curtain effect is, that between each slide, the screen having been made black for a few seconds by the curtain rolling down, the eyes are relieved from the great glare; and each picture all through the entertainment comes as fresh and bright to the eyes of the spectators as the first slide exhibited.

The space below the floor of the lantern proper, on which the lamp or lime burner stands, is utilised for holding a Russian iron box, which contains sixty photographic slides, and an oil-can large enough

for holding sufficient petroleum for a two hours' entertainment' besides space for chimney and tools.

Acquainted as we are with the various ingenious contrivances invented by Edwards, Davenport, Cowan, and others for producing dissolving or curtain effects by a single lantern, we think that in this "Terpuoscope," which is complete in itself, is to be found such a balance of advantages as will secure for it an enviable position amongst the high-class lanterns of the future. We need scarcely add that the Terpuoscopic system can be applied to every lantern the optical system of which is the requisite height from its floor.

ILLUSTRATIONS (1, St. Swithin's-lane) this month is exceptionally valuable from its containing an admirable portrait of the late Wilkie Collins, printed in phototype, the text matter accompanying which is written by Charles T. J. Hiatt. In addition to numerous other "illustrations," in all cases nicely printed, there is a full-page one (in phototype, by Meisenbach process) of the marble group *Hylas and the Water Nymphs*, by John Gibson, R.A.

THE COVENTRY EXHIBITION.

This Exhibition, which opened on Tuesday evening, remains open till Saturday evening. It is a very successful one—many high-class artists contributing. Silver medals have been awarded to Messrs. Lyddell Sawyer, A. Seymour, T. W. Owen, and W. D. Welford; and bronze medals to Messrs. F. M. Sutcliffe, J. E. Austin, J. W. Green, T. H. Faulks, B. J. Wilkinson, and W. W. Winter. There may be others besides those named, but the foregoing are given in the local paper from which our list is compiled when going to press.

PATENTS COMPLETED.

IMPROVEMENTS IN MAGIC LANTERN SLIDES AND APPARATUS IN CONNEXION THEREWITH.

No. 16,785. WALTER POYNTER ADAMS, Springwell, The Terrace, Barnes, S.W.—September 28, 1889.

My Improvements relate to the substitution for glass of a flexible and transparent support for the picture, in slides used with the magic or optical lantern. Gelatine, algin compounds, and celluloid are suitable for this purpose.

Slides made with such substitute may be of the usual square form or in strips.

The following is a description of one way in which a series of photographic views may be produced, in a strip, with gelatine as the support:—

Each view is printed on a special paper known to the trade as "transferro-type paper," and then squeezed in a row on to a smooth, even surface—glass will do—carefully levelled and previously polished with French chalk; when dry the paper is removed with hot water, leaving the picture film adhering to the glass; over all is flowed a solution of gelatine so as to form an even layer. A solution of gelatine prepared as follows gives good results:—For a series of twelve views three and a quarter inches square—the glass being about four inches wide—dissolve three-quarters of an ounce of gelatine in eight ounces of water; this is filtered and applied hot. When "set" it is soaked for five minutes in a saturated solution of chrome alum, to render the gelatine insoluble; it is then well washed, and again soaked in a solution of one ounce of glycerine in fifteen ounces of water. When thoroughly dry the strip is cut to the required width, and a length of four inches left at each end for attachment to rollers; then the whole layer of gelatine, with the picture films adhering, may be stripped from the glass.

In connexion with the strips of pictures I use roller holders to bring each view into place in front of the lantern condenser.

The rollers are placed on opposite sides of a frame, whose position when in use is in front of the condenser, and the strip is wound on to one roller from the other, so that each view passes the condenser in turn.

The movement of the rollers may be accomplished by hand or mechanically. Claims:—1. The employment of a flexible and transparent substitute for glass as the support for the picture in optical lantern slides. 2. The employ-

ment of roller holders in connexion with the flexible and transparent strip lantern slides.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 14,652. WILLIAM HUGH RUBENS KERRY, Manor House, Poolton, Wallasey, Chester.—October 3, 1889.

This invention has for its object a photographic camera that will be, as much as practicable, self-contained. In its most improved form it will carry its own plates, and automatically, or almost automatically, change an exposed plate for an unexposed one, so that views can be taken in quick succession. It can be carried under the arm, and the image found and focussed from the top, and then the exposure is instantly effected, without having to alter the position of the sensitive plate, focussing glass, or screen in any way.

In carrying out my invention, I prefer to form the frame of the camera as a simple rectangular box, formed of three main chambers—the ordinary body of the camera, a chamber above this body, and a chamber in front, holding the shutter, the lens, and the focussing glass, or screen. This box has preferably three orifices, one immediately in front of the lens, one immediately above the focussing plate, and the third (which is not necessary, but useful) immediately behind the sensitive plate carrier, at the back of the carrier. These are all supplied with opaque slides or lids.

On the shutter, considerably above the exposure orifice, I place a diagonal reflector, so arranged that, on this reflector being brought immediately behind the lens, the image shall be reflected on to a ground glass (or focussing screen); immediately above the ground glass I place an orifice, normally closed by a sliding shutter in the top of the camera.

The exposure shutter is supported by springs from above, or is otherwise counter-balanced, so that when pulled down by means of a string at the bottom, or the winding up of a roller, or otherwise, it shall spring back, thus taking the reflector away from the back of the lens, and immediately and momentarily exposing the plate by causing the exposure orifice to pass between the lens and the said plate, the shutter stopping when its perforated portion has passed beyond the lens. The lower part of the shutter can be formed of opaque cloth, or can be of wood, or other material; and if required to pass through the bottom of the camera, is protected by a waterproof or other opaque bag or sleeve. In practice, however, this can be obviated by causing it to be wound round a roller, instead of being drawn out through the bottom by means of a string. A spring catch, which can be released by a button or spring from the outside, holds the shutter when it is in its lowest position with the reflector immediately behind the lens.

A little in front of the shutter, between the lens and the top of the camera, I place a shield of cloth or other material, so as to prevent the light which passes through the orifice in front from striking the focussing lens; or, in place of this, a box can be placed in this position, carrying a dark lantern or other useful apparatus.

The opaque slides of the orifice of the focussing plate and the lens are connected, being preferably supported on a web or band, passing over rollers, and kept in the normal closed position by a strong spring. By this means both openings are exposed and closed at the same moment, the strong spring instantly closing the openings whenever the spring catch holding them is released. This spring catch can be of any convenient arrangement, but is so placed as to be released by the exposure shutter whenever the latter lies to the top of the box; and indiarubber buffers are also preferably placed above this catch, or any other convenient position, to buffer the slide when it arrives at its highest point.

Immediately above the camera body I place a second chamber, containing the carriers with their plates, and also a light block or blocks to fill up the remaining space not occupied by the carriers and plates. The carriers can be of any suitable material, preferably of thin cardboard, ebonite, Willesden paper, or other light material, so as to occupy as little space as possible, and yet entirely cover the back of the plate and protect the edges in front, so as to prevent the back of one carrier touching the plate of the next carrier. As many plates as are required for the day are placed in this chamber, and then the block of wood or other material is placed in front loosely filling the remaining space. Two or three sizes of blocks can be kept in stock, so that any one of them can be used as required. A slit in the bottom of this chamber at each end—just large enough to allow a plate and its carrier to pass, but not large enough to allow the block to do so—enables the plates to be passed from the chamber into the carrier frame at the back end, and from the carrier frame afterwards to the front end of the chamber in the manner hereafter to be described.

In the body of the camera I place at the right distance from the lens, and immediately below the back slit in the chamber above, a carrier frame with a slit in the top to enable plates and their carriers to fall into it. This carrier frame has mechanism for drawing it forward, preferably a string at each end passing to a windlass in front beyond the exposure orifice, and in order to enable the windlass to pull absolutely evenly, these strings instead of being each separate are united together at the back of the carrier frame. By, therefore, turning the windlass the carrier frame is drawn forward from one end of the body of the camera to the other, so that it shall come immediately below the front aperture leading from the chamber above. In order that it may be drawn back automatically after having got rid of its plate in the manner hereafter described, the carrier frame is fastened by two or more strings, preferably two above and one below, to a spring roller similar to a blind roller. The two strings at the top, or at the bottom, as the case may be, or in both cases, are united together, being simply attached to the carrier frame by eyelets, so that they can allow for any variation in winding up. Any other arrangement by which the carrier frame can be brought forward in a direction perfectly parallel with the front and back and allowed to fly back by means of a spring can be used instead of the above apparatus. In order to close the two orifices when the carrier frame is travelling, and thus prevent plates falling down into the body of the camera, two bars or shutters are employed, regulated by springs, but preferably connected together at each end by a single spring uniting the two, so that whenever the carrier frame is in an intermediate position these two bars close the orifices, but the moment the carrier frame begins to come into position under either orifice it pushes the bar before it and takes its place. The shutter in the sight hole at the back of the body of the camera is provided with an ordinary

shutter and catch. The space between the upper chamber and the back of the camera, namely, that part just above the roller can be used to keep spare carriers or for any other object.

The mode of actuating is as follows:—A sufficient number of plates and their carriers having been placed in the upper chamber at the back of the block to form a day's supply, the camera is carried out under the arm, or if desired it can be placed on a tripod in the usual manner, slides being fixed on the bottom of the camera to fit the tripod. When a view is required to be taken the shutter is pulled down to its utmost tether, by this means the reflector attached thereto is exactly behind the lens, and a catch holds it in place. The two shutters closing the orifices to the lens and the focussing plate respectively are now drawn back against the pressure of their spring, and an image is arranged and focussed by means of the focussing plate or screen and the ordinary focussing screw. The moment the image is exactly right, as seen from the focussing plate, the spring catch holding the shutter is touched and the shutter released. The powerful springs attached to the latter draw it up, momentarily exposing the plate as the orifice in the shutter passes the orifice into the body of the camera. The moment the shutter reaches nearly the highest point it comes in contact with the spring catch which holds the shutters of the two orifices open, and these are instantly closed by means of the spring attached to them. The carrier frame is now drawn forward by means of the windlass until it arrives immediately below the front carrier orifice. The camera is now inverted, the carrier and plate fall through the orifice into the upper chamber in front of the block, when a slight tilting causes them to fall back against the block or the last plate that has been exposed. The windlass is now let go, the carrier frame flies back, allowing the bar or shutter in front to close the front carrier orifice, the frame then comes in contact with the shutter of the back carrier orifice, pushing it away and taking its place. Another carrier and plate now immediately falls down into the carrier frame, and the apparatus is ready for another focussing and exposure.

In order to regulate the duration of exposure, a simple straight shutter pulled down may be used. I attach weights to the strings; if it be wound on a roller I use retarding or accelerating devices.

As in focussing it is rather difficult to see the image clearly when the light falls on the top, I box the focussing plate in with a fixed or moveable box having a hinged or moveable lid, composed of a lens and its frame. The image first seen in its exact size on the focussing plate, the lens is now placed in position, and the image is magnified, and so more perfectly focussed. This camera can be adopted for taking long exposures by the addition of an ordinary flap or other shutter, or a small stop device can be added to the shutter already described to stop it half way, and thus let it remain open as long as desired. When the stop is withdrawn it closes instantly. When an iris diaphragm is used, its outer milled rim or equivalent is connected with a notched handle or the like outside the camera by means of levers, links, or other mechanism.

The claims are:—1. In a photographic camera, the combination of a box or chamber to contain sensitive plates, and having a slit at each end thereof, a reciprocating plate carriage within a second chamber adapted to receive a plate dropped through one slit and to transfer it again to the first chamber through the other slit when the position of the camera is reversed, substantially as described. 2. In a photographic camera having a moveable carriage for transferring the plates from one end of a chamber to the other, an externally operated winding device connected to the said carriage to effect a steady, forward movement of the same, and a spring device adapted to effect its return, substantially as described and for the purposes set forth. 3. In a photographic camera, the combination of an exposure shutter capable of movement behind the lens, and a reflector capable of rectilinear movement, and adapted to reflect an image on to the focussing screen, and of being drawn aside either attached to the shutter or independently in the manner described, whereby a smaller reflector will reflect a given sized image than is possible with the ordinary hinged reflectors. 4. The arrangement of a small moveable mirror immediately behind the lens, as described in place of the large hinged mirrors now in use, whereby a larger image can be reflected with a smaller mirror than is possible on the old plan. 5. The improved photographic camera, taken as a whole, substantially as described and shown.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 24.—Mr. A. Haddon in the chair.

A question from the box was read:—"What is the best method of producing negatives in the studio in misty weather?"

Mr. F. A. BRIDGE suggested using isochromatic plates, and giving ten times the usual exposure.

Mr. W. E. DEBENHAM said that insufficiency of light was not the great difficulty in the way of producing good negatives in the studio in misty weather, but the presence of particles in the atmosphere, which, being illuminated, caused a veiling or fogging of the shadows. To minimise the evil, as short-focussed a lens as would serve the purpose should be used, as of course the nearer the camera is to the sitter the less thickness there is of misty atmosphere to contend against. For full lengths and for any purpose where it is not practicable to be near the sitter, he used a framing covered on the top and one side, which shaded the air for the greater part of the distance through which the light had to travel from the sitter to the lens. Of course, too, a good fire in the studio would dissipate a great deal of the haze.

Mr. BRIDGES remembered a few years ago he had seen some such arrangement as the shade described by Mr. Debenham in a West End studio, and he understood that it was effective.

Mr. W. H. HARRISON said that the air should be filtered through wet screens of coarse canvas, as was done in the House of Lords.

Mr. A. COWAN had known cases when he could not get a full-length portrait on account of the mist present, but had succeeded with a large head when the camera could be brought near the sitter.

Mr. Morgan exhibited a camera by Mr. Jowett, of Romiley, Stockport, in which the back was made to revolve so as to serve for either the landscape or the upright plate, and that without increase of size of the instrument. Another point in the camera was the manner in which the front was given a considerable amount of play, both laterally and vertically. The dark slide also might be inserted at either end of the camera back, and when used vertically might be inserted downwards from the bottom instead of the top, and the shutter is then drawn—a consideration that would be appreciated by those who used large cameras.

Mr. J. HUBERT then read a paper on *Bronze Enlarging*, and afterwards proceeded to demonstrate the process in the presence of the members. In the course of his paper he recommended those who used daylight for enlarging to employ a sheet of tin coated with Aspinall's or other pure white enamel outside the negative as the source of illumination to form the image. Personally, he had abandoned daylight work, as the exposures were so variable, and used a lantern. With an oil or gas lamp, he said, it is well to interpose a diaphragm between the flame and the condenser to cut off all but the most luminous rays, else sharpness of the image is decidedly impaired. In case the operator can avail himself of the limelight, he may modify the character of his negatives somewhat by using more or less hydrogen. A very weak negative might be improved by coating the back of the negative with a varnish coloured yellow with iodine. An old cap cut out in the centre, with a piece of yellow glass inserted, was recommended as permitting of the easy adjustment of the sensitive surface by cutting off all but the yellow rays, which are, of course, non-actinic. He recommended making trial exposures by passing a long strip of the sensitive paper through two pieces of brown paper fastened at the sides. The length of the exposure having been marked on it with pencil, it is drawn downwards a few inches, which will, of course, place another portion of bromide paper in position. Dishes for large-sized papers can easily be made out of cardboard; with care they last a long time. One of the large straw-boards is turned up to the depth of one and a half or two inches at the edges all round, fastening them with paper fasteners. Then melting in a common or silver pot a pound or so of wax candles, the fat must be applied to it hot, previously heating the dish all over. When cooled down the tray is ready for use. He concluded his paper by saying that it would now devolve upon him to practice what he had preached. The fear of boring the members with the length of the paper had already proved a strain upon his nervous system, so he begged them not to be too severe upon him whilst he waded practically through a process—perhaps interesting to them only by providing an amusing sketch of the blunders which, alas! even an experienced photographer may commit. The demonstration which followed did not, unfortunately, prove successful. After the trial-pieces had been exposed and developed, the demonstrator considered that a smaller supply of gas would suit the subject better, and lowered it accordingly. The succeeding trials, however, scarcely yielded an image, a circumstance which he attributed to the zinc can from which the water supply had to be obtained. Discussion on the paper was adjourned to the following meeting.

Mr. COWAN handed round two lantern slides to show the slowing action produced by the addition of carbonate of ammonia to the developer, an effect which he had referred to at the previous meeting. The slides had been equally exposed, and developed to the same intensity, but with the carbonate of ammonia six minutes had been required, whilst the same amount of action had been obtained with the other solution in two minutes. Mr. Cowan also showed two slides developed with pyro ammonia and sulphite of soda. One slide had pronounced green fog, whilst the other was remarkably clear. The difference was only in the particular samples of sulphite used. Very contrary experiences as to the production of green fog by sulphite of soda might thus be explained. Another pair of slides exhibited the clearing effect on the shadows on the addition of disulphite of potash to the hypo-fixing bath, in the proportion of one to six of the hyposulphite of soda.

It was decided to have a discussion at the meeting to be held on November 7 on the variations of samples of sulphite of soda that would or would not produce green fog.

The CHAIRMAN asked if Mr. Cowan would bring with him some of the particular kind that had given green fog in his case.

Mr. COWAN regretted that he could not, as it had been thrown away.

CAMERA CLUB.

THURSDAY, October 24, was the first lantern evening of the season at the above Club. Slides by members and friends are shown at these meetings, one of the regular Thursday evenings each month being devoted to the exhibition. On this occasion there was a large and varied collection of transparencies, about ten members bringing or sending up contributions. Altogether about one hundred and sixty slides were passed through the lantern. The chief exhibitor was Mr. T. M. Brownrigg, who exhibited and described a fine series, including views of the Lake District, of Italy and the South of France, at the Paris Exhi-

bition, &c. These gave much pleasure, and Mr. Brownrigg's humorous recital of his experience in photographing the pictures added much to the merriment of the evening. Mr. T. Charters White showed microscopical work and some capital landscapes; Mr. W. A. Greene, mountain scenery from negatives taken on stripping films in a hand camera; Mr. Humphery, Italian views; Mr. J. H. Williams, country views, including one or two charming cottage bits; Mr. Gowan, a varied set; Mr. Hausard, very fine photographs of the Alhambra. (These were beautiful in colour); also pictures by Mr. F. Howlett and others.

Mr. J. F. Roberts had the management of the lantern.

During the evening a small electric dark-room lamp was exhibited by Mr. Freshwater.

On Thursday, November 7, Mr. A. Pringle will give an address on *Exposures*, illustrated by photographs and lantern pictures. Meeting at eight p.m.

WEST LONDON PHOTOGRAPHIC SOCIETY.

OCTOBER 25.

The PRESIDENT (Mr. Charles Belton) gave an address, and acknowledged the honour which the Society had conferred upon him in electing him to the post of President. He felt conscious of many shortcomings, but, with the co-operation of the Council, he hoped to hand over the Society to his successor in an even more prosperous condition than it was at the present time. He wished now to acknowledge, on behalf of the Society, the services rendered by his predecessor, Mr. William England, whose name was well known; and he considered the Society had been fortunate in having so eminent a photographer for its first President. They learnt, with regret, that he had considered it desirable to resign, but he was sure whenever he felt a desire to attend their meetings a hearty welcome would await him. The President, continuing, said every individual ought to have a hobby of some kind, and all would agree that a more attractive and interesting one than photography could not be found. Photography tended to cultivate the qualities of patience and perseverance, and its pursuit promoted a love of the beautiful and grand in nature. Again, the practice of photography was *suggestive*, and led its followers to experiment, paving the way to future discoveries. Some might be led to study the laws of optics or the science of chemistry, subjects as delightful in their own way as photography itself. The man who could follow the chemical changes which occurred would derive an enhanced pleasure from his work. He would also refer to the opportunities afforded of giving pleasure to others, lantern evenings being always popular and much appreciated.

Slides by Messrs. Power, Rickford, Scanlan, Horton, Kellow, and Wilson were exhibited by the optical lantern.

The next meeting takes place on November 8, when Mr. Lyonel Clark will give a demonstration of his platino-toning process.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

OCTOBER 17.—The members of this Society held their first annual dinner in the Masonic Hall on Tuesday evening last. There was a good attendance. The Vice-President (Mr. T. Firth) presided.

An interesting collection of photographic views—all members' work—was exhibited, many of the pictures having medalled at the various exhibitions. The work sent in for competition for the Society's silver and bronze medals and other prizes was also hung, and came in for a fair share of commendation by all present.

Mr. W. B. HATFIELD proposed success to the Sheffield Photographic Society, and in so doing remarked that the Society had held its own very well, and now stood better than it had ever done. The work exhibited was good evidence of the perseverance and ability of the members.

The PRESIDENT, in replying, expressed his pleasure at the manner with which the toast had been received. The Society had commenced in a small way, and he was pleased to see around him gentlemen who were in at the beginning. True, some had, after continuing for a time, tired and fallen away, yet their presence there was good evidence that still they were at one with us. He was exceedingly proud of the work exhibited; it would stand the severest criticism both for *technique* and artistic quality. In art work the photographer laboured at a disadvantage as compared with his companion knights of the brush, who were able to leave out such of the surroundings and add other items by way of improvement to their productions as was deemed necessary, whereas the lens took in all the small details, whether in balance or not; therefore it behoved them to study with all the accessories used, and add only such as agreed with the composition of the picture desired to be produced.

The next item was the presentation of the Society's silver and bronze medals, and other prizes offered during the year. The SECRETARY having stated the particulars of the several competitions, the awards were presented as under:—"Best series of six pictures"—Silver medal, Ernest Beck; bronze medal, J. W. Charlesworth. "Best single picture"—Mr. Beck. "Best series of three under whole-plate"—Mr. Beck. "Best three stereoscopic prints"—Mr. Bromley. "Best set of six lantern slides"—Mr. Furniss, first; Mr. Beck, second. "Study taken against the light"—Messrs. Beck and Hibbert equal winners.

Mr. ALLEYNE REYNOLDS then submitted "The Advancement of Science," and in so doing he pointed out that photography played an important part in scientific research; for instance, the recent discoveries in astronomy were in a great measure due to it, and here a necessity for faster plates was apparent in order to go further and deeper and more correctly into the subject. The microscopist used it for a better study and teaching of the minute things of creation, and in such had made great progress. The medical faculty also admitted the uses of photography into their researches, and in fact every scientific branch found in it means of advancement.

Mr. HOWARTH, in responding, expressed his pleasure at the happy reception of the toast, and spoke at some length on the recent researches and discoveries made in animalia. He believed that further investigation would reveal greater and more startling facts. He contended that every photographer should be a competent chemist, an enthusiastic and persevering student of science in all its branches, and have a good knowledge of the canons and laws of art in order that his productions should give satisfaction.

Mr. PRESTON submitted "The Advancement of Art," and urged the members to study art in their work. He spoke at some length on the mutual aid that the artist and photographer might render to each other and in many ways give assistance. He contended that each exposure should be well studied, and if on looking at the ground glass of the focussing screen anything was found wanting it should be either procured or the exposure not made.

Mr. F. SALTFLERT, in replying, pleaded not guilty to the impeachment of the artist adding accessories to his painting and removing other items visible in the original, and he claimed truthfulness in the sketch, and a close following of nature in her many moods as the surest way to success. Apart from being a theorist only, he claimed to be a practitioner, and had already found an advantage in the use of the camera as an aid to his work.

Other toasts followed, and songs, recitations, and music were rendered at intervals. A series of lantern slides illustrating the Paris Exhibition were also exhibited, and at a late hour the party separated, having passed an enjoyable evening.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

OCTOBER 17.—The President (Mr. P. Lange) in the chair.

The PRESIDENT read a circular referring to a course of lectures on photography to be given in the University College, Liverpool.

Mr. THOMAS COMBER, J.P., then read a descriptive paper on *Photo-micrography*, during the course of which he passed round several prints of microscopical objects, and also showed some fine slides, through the lantern, of diatoms, &c.

NOTTINGHAMSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.

OCTOBER 28.—Mr. G. A. Bull (President) in the chair.

A mass of correspondence was read by the HON. SECRETARY (Mr. P. E. Knight) relating to the forthcoming *conversazione* and exhibition of photographs, cameras, &c., to be held on Monday, November 11, in the Castle Gate Lecture Hall. Further additions of photographs from Mr. I. Furley Lewis and Mr. R. S. Armitage for decorating the walls were acknowledged.

The HON. SECRETARY also announced the formation of an instruction class for beginners, Mr. T. Carnell undertaking the duties of instructor. A set of twelve phototypes, kindly lent by the Ilford Plate Company, showing the terrible results of the explosion at Antwerp on September 6, were exhibited.

Mr. R. S. ARMITAGE gave a practical demonstration on lantern slide making, and explained the different ways and means of obtaining the best results. Mr. Armitage then proceeded to expose, by means of gaslight, plates of different makers, including Dr. Backelandt's water developing plates, and was highly successful in the results. The mounting and finishing of the plates were also practically shown.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

OCTOBER 2.—Mr. Frederic Graff (President) in the chair.

A paper on the new developing agent known as *Eikonogen* was read by Dr. MITCHELL [this will appear subsequently].

Referring to the statement that the solution was green in colour, Mr. BULLOCK remarked that the pure aqueous solution was pink, and that the green colour was induced by the sulphite of soda contained in the developing solution.

Mr. WALMSLEY spoke most favourably of the new developer, stating that he had used it without the addition of any alkali with excellent results.

Mr. BULLOCK thought this was owing to the presence of some carbonate of soda in the sulphite.

Mr. WOOD had found difficulty in correctly timing the exposures of transparencies on slow gelatine plates, but with plates as rapid as Cramer's 50's, at a distance of ten to fifteen feet from the source of light, he had obtained excellent and certain results with about one second's exposure.

Messrs. RAU and DILLON questioned whether a desirable colour could be obtained with such rapid plates.

Mr. SUPPLEZ called attention to some plates he had recently seen coated with an opaque varnish for use in that species of etching in which a glass plate forming a negative was used instead of a copper plate and the usual process of biting by use of acid. The process was similar to that in use for twenty or thirty years, in which a plate was coated with collodion, sensitised, exposed, and developed, and then used as a surface on which to operate with an etching needle.

Correspondence.

✉ Correspondents should never write on both sides of the paper.

BLACK MATT PRINTING.

To the Editor.

SIR,—There is evidently a great amount of interest shown in the above subject. It has occupied my attention for about two years, during which time I have been constantly working it, having during a course of experiments discovered a very successful, simple, and certain mode of working. The difference between mine and the usual treatment of albumenised paper may briefly be summarised as follows:—

1. Any suitable paper may be used and salted in the usual way.
2. The floating (sensitising) bath is prepared with modifications and additions of an important character.
3. After printing in the usual way the prints are washed thoroughly, but to the last water but one a few drops of a concentrated solution are added to every pint of water; this I term the preparatory bath.
4. Two toning baths are used. The prints are first immersed in bath

No. 1 till they assume a rich chocolate; they are then slightly rinsed, and placed, one or two at a time, in bath No. 2, which acts *very rapidly*, a few seconds only being necessary to produce a beautiful velvety black tone, which *does not alter* in the fixing bath.

5. Both toning baths keep indefinitely, and there is, therefore, no waste of toning solutions; occasional strengthening keeps them always in working order.

I notice the summary of a paper read by Mr. Clark before the Camera Club: the results he obtains would, I imagine, be somewhat similar to mine. I have not yet seen any results by Mr. Blanchard's process, but expect they also will be similar.

I, however, claim priority of introduction. Two seasons ago I exhibited a number of prints, being reduced representations of charcoal drawings; from that time till now they have been exposed for sale in one of the art shops in Nottingham.

I have sent three small frames to the Pall Mall Exhibition (P.S.G.B.) now open, Nos. 119, 201, and 356, but, unfortunately, no mention is made in the catalogue of the special means of production. I was quite unprepared for the Exhibition, or would have sent additional work in the form of views, and with much regret I was unable to do so.

Apologising for the space I occupy, which is only warrantable on account of the importance of the subject,—I am, yours, &c.,
Nottingham, October 29, 1889. S. ROBERTS STEVENSON.

LANDSCAPE ART.

To the Editor.

SIR,—Mr. Davies's reply to my questions about his remarks on landscape art is going so far from the point that it is impossible to consider it a satisfactory answer. That the development of the landscape art is comparatively newer than historical art is an undisputed fact; but whether photography has anything to do with this development, that is quite another question. A long time before photography was thought of the landscape art was as highly developed as it is now, and for this reason can the "one remark" about *Liber Veritatis*, &c., not settle the matter. Likewise is the quotation from the editorial column of this JOURNAL not coming to the point, as there was never said or hinted anything of "revolutionising" the landscape art.

Relative to the second point, about "several of the most famous names in art circles" using photography in the way indicated by Mr. Davies, I can only say that any one acquainted with painting will easily understand that a design of a landscape, produced on canvas by photography, will never give the painter any advantage whatever, as, for instance, any line over-reaching the sky would disappear by painting the sky, &c. Besides, the landscape art depends entirely on colour. Vegetable life is prominent, but it is expressible only as it becomes in harmonious unity effectual to the whole, and for this fact any design in the way of a photograph can be of very little consequence to the artist.—I am, yours, &c.,
38, Crown-street, Liverpool. F. B.

TUNBRIDGE WELLS EXHIBITION.

To the Editor.

SIR,—May I ask you to be kind enough to announce that the third Annual Exhibition of the above will be held on November 23 and 24, and that there are classes for amateurs and professionals? Silver and bronze medals are being offered for competition. Entry forms and all particulars can be obtained of the Hon. Secretaries, Joseph Chamberlain, 14, Calverley-park-gardens; B. Whetton, 15, St. John's-road. By so doing you will greatly oblige, yours, &c.,

JOSEPH CHAMBERLAIN, Hon. Secretary.

14, Calverley-park-gardens, Tunbridge Wells, October 28, 1889.

AMATEURISM.

To the Editor.

SIR,—From the tone of a recent letter which appeared in this paper over the signature "An Amateur," I opine that in the event of professional photographers declaring open war against the so-called amateurs of the present day, they will have on their side the moral aid of the true amateur. Before going further, it will perhaps be advisable to distinguish between these two—the so-called, or rather the self-called, amateur and the true. To take them in their proper order, "the true amateur" is he who from a natural love of the beautiful in art and nature pursues the art—science of photography at his own expense—that is to say, he does not interfere with it in its commercial aspect; he takes photographs because it is his own sweet will to do so, and would consider it beneath him to sell his productions for money. The true amateur may be a rich man, he may be poor; but, whichever be the case, he does not begrudge the cost entailed in the pursuit of his study. He does not want to fill his pockets at the expense of his neighbours; all his ambition is to produce good work, that he may gaze upon and show to his friends as produced by himself. All honour to such men, say I, for in their unselfish love for the art they do far more good than harm. The amateur, as a rule, has more time at his disposal for experiment than has the professional, and photography has at various times received much and substantial aid as the outcome of the experiments of such men, and, what is more, has received it

freely. The amateur who makes a discovery that has any bearing on photographic progress is usually only too ready to present the same to the profession. The roll-call of the amateur photographer contains the name of many a good man and true, and if at any time my pen may seem to cast discredit on the amateur, I trust it will not be imagined that it is to such men as these that I refer.

Now for the other section—the self-styled amateur, who is really a sort of hybrid, or, so to speak, an “amateur-professional,” by which title we should do well to distinguish him from the more honourable and true amateur. The amateur-professional, then, is one who would consider himself degraded by openly working at a trade, for as such he usually designates professional photography, and yet, forsooth, he actually carries on a trade under the rose while designating himself an amateur. He has no recognised place of business, he does not advertise for work in the papers, or issue circulars or price lists to his customers, but he still puts a price upon his work, and by so doing places himself in antagonism to the “tradesman” he looks down upon; in point of fact he is a professional, if we take the rule that “an amateur is one who does not work for money, or has never competed with a professional or for a money prize.” If, then, he is a professional, to what branch of the profession does he belong? From the fact of his having no recognised place of business, and obtaining what work he does by touting, together with the similarity in his scale of charges and in the general quality of his work, I can only class him with that branch of the profession we meet with on the sands or at a country fair, or, say, on the roadside near any favourite suburban resort. Whether the cash obtained in this way goes into the pockets of the amateur-professional himself, or into the coffers of a charity (*sic*), matters little to us; the fact remains that it is taken out of our pockets,—indirectly, perhaps, but nevertheless, surely. As these men increase, so does our work decrease in a corresponding ratio, and wherein lies the remedy? “An Amateur” thinks an appeal to the gentlemanly instincts of these hybrids might be effectual. I venture to differ with him, as I opine that in nine cases out of ten these instincts are absent. The man who calls himself an amateur and acts as a professional is not likely to heed such an appeal; besides, he will tell you he cannot afford to give his work away; it costs him money, and he must have that money back. In justice to such men, I will admit that they act fairly to their customers; they put a fair price upon their work as a rule, and they do so advisedly, for they know that they dare not ask the price that the professional claims as his due. Unfortunately, however, the idea is spreading that professional photographers obtain an exorbitant and unreasonable profit upon their productions, such idea being caused and fostered by the prices charged by the amateur-professional, and the fact being ignored that the professional “has to pay high rents for situation and to keep an effective staff.”

“An Amateur” says that “men claim a legal and moral right to act thus.” So far as legality goes I say nothing, but the moral law is a different matter. I have yet to learn that it proves morality in a man to take the bread and butter out of the mouth of another when he has no need for it himself. Genuine business or professional competition is one thing, unfair competition such as this is of an entirely different complexion. That “they even claim to be charitable by ruining their neighbours” I admit, but then charity always did cover a multitude of sins, and I always look with a certain amount of distrust on obtrusively charitable people. It is very easy to be charitable when you have the means, especially if you obtain those means at the expense of others.

By all means let photographers, both amateur and professional, speak out upon the subject at once; let them show the amateur-professional the light in which they look upon him. It is utterly useless to disguise the feeling that there is with regard to this middleman, who has not only been harming the professional, but has been materially damaging the true amateur, between whom and the professional there had hitherto been a thorough *entente cordiale*; but whose relations have become strained owing to the difficulty, in many cases, of distinguishing between the true amateur and the false. Photographic dealers have been blamed by many as the main cause of the present amateur rage. It is alleged that they supply amateur and professional alike at the same prices, although the former naturally purchases in much smaller parcels. Manufacturers of plates and chemicals do the same thing, and it is here the blame is mostly deserved, although it should be noted that they supply dealers at a much less rate. For example, if a professional photographer applies to the manufacturer of dry plates direct for a quotation, he is told that they can only supply him at the same price as he can obtain the goods from a dealer. Now, a photographic chemist in a small way ranks as a dealer, and obtains a discount upon his orders, while a professional photographer who purchases ten or twelve times the number of plates at one time, receives no discount at all, and, in point of fact, pays the same price per dozen for eight or a dozen gross as he would pay if he procured his plates by the single dozen from a dealer or a small photographic chemist. This is manifestly unfair to the large consumer and is not the case in any other business or profession.

Although agreeing so far with those who accuse manufacturers and dealers of helping the amateur-professional, I cannot agree with them in the idea that if the professional obtained his materials at a less rate he might fight the amateur-professional by approximating his prices. This would never do; let the professional keep up his prices, and, above all, keep up the quality of his work, taking care that no one shall be able to compare his productions unfavourably with others produced by his rival.

In conjunction with “An Amateur,” I anxiously await to hear the voice of others on the subject; it is useless to pretend that it does not interest us, as it clearly touches each and every one of us; not only those with businesses of their own, who are employers of labour, but *employés* equally with employers, as, if the work fall off, less hands will be required to do what is left, and consequently the number of the unemployed will be increased. A serious danger is threatening the profession, and it is now high time that the profession awoke to the fact and devised means to combat that danger.

G. BRANWIN BARNES.

6, Victoria-street, Windsor.

To the Editor.

SIR,—Referring to that vexed question of Amatenism, may I be allowed, from a humble place in the ranks of the profession, to suggest to amateurs that they charge the full market value of the work they supply? It is manifest that amateurs supplying photographs cheaply, or at cost of the materials, must do the profession some harm, as there are many people who would take anything for cheapness; but, charging a fair price, all work would stand on its own merits, and the number of amateurs the profession has to fear would be very materially reduced.

I do not share the opinion of so many people as to the great harm being done by the former class to the latter. Most of the business of a professional photographer lies in portraiture, which few amateurs attempt beyond the circle of their intimate friends, and friends, as a rule, don't think much of one another's work—“A prophet hath no honour in his own country.”

I cannot see, however, why a man who devotes only part of his time to photography, and yet produces work *equal* to a professional, has not a perfect right to sell it. That is only in accordance with free-trade principles. The harm and *real injustice* lies in the work being sold *too cheaply*.

I hope the time is not far distant when the objectionable distinction will be forgotten, and both amateurs and professionals will work together as brother artists.—I am, yours, &c.,

M. W.

Chelsea.

To the Editor.

SIR,—The letter signed “An Amateur,” which appeared in your issue of October 25th, raises a question which has been much discussed, and which if let alone I fancy will settle itself.

“What is an amateur?” is a question which needs settling before a letter such as “An Amateur's” can be answered. I am an amateur, and have no intention of becoming anything else, and yet I am prepared to take pay for the work which I produce. I am an amateur because I do not make a business of photography, but I suppose “An A.” would dub me a “pro.” because I take pay for what I do and what people of my acquaintance desire to possess. I go out with a picnic, and in a suitable place and suitable circumstances take a group which never would have been done had it depended upon professional skill. I take a church for which a bazaar is being held, and supply a dozen copies for people who desire them, and so assist the funds. I take a landscape which cannot be had from any professional, and supply copies to people interested in the scene, for which I am paid. Am I, because I am an amateur, to refuse to do these things simply because “An Amateur” chooses to style me “No gentleman?”

It is too late in the day to attempt to set up monopoly in anything, which appears to me to be the purpose or desire of “An A.” The only way left for the profession is to make their work superior to that of the amateur, and so long as they do this there is no fear of ruin from cheap competition.

“An A.” suggests the possession by the professionals of suitable plant for the purpose of their business. With this and the practice they have, competition from amateurs ought to be impossible, but if they turn out work which can be equalled or surpassed by amateurs let them take the consequences.

I am proud in knowing that we have such complete liberty of action in our great and free land that, so long as we do not inflict injury to our neighbour by interference with his lawful rights, we are at liberty to do anything which pleases or profits us.

My own honest impression of the supposed injury to the profession by amateur work is that it is a myth, as I don't think the profession was ever better patronised or more liberally paid than it is at the present moment. I admit that there is now little room for “quacks,” and well it is there is not, for their work is worth little more than what is obtained by the average amateur—nothing.—I am, yours, &c.,

ANTI-MONOPOLY.

To the Editor.

SIR,—“Amateur,” in your last issue, writes very absurdly. Professional photographers are not fools; as men fitted to enter business with some prospect of success, they study well the *pros* and *cons* before they make the venture. No sensible man would place his capital in any business whose condition of success depended on the army of amateurs, or pretended amateurs, not doing what “Amateur” tells us some do.

Amateurs, or pretended amateurs, have *truly* a legal and a moral right to sell their labour at what price they think proper, or to give that labour free, if it be their pleasure. It is presumption and impudence in any man to find fault with them for so doing.

Professional portraiture is a small item in photographic work. Photography soars higher, and these higher flights are by amateurs.

But to return. Let me tell "Amateur" that the "pent-up smothered ill-feelings" of which he writes are not in the professional photographer. No, they exist, I am happy to say, in a few only of men of independent means, who have taken to photography as a pastime, and who imagine their social position lessened by being classed with others less fortunate than themselves under the name *amateur*. This is the real sore, and is the root of the amateur question.

Exhibitions and prizes given settle the question, "What constitutes the amateur competitor?" which is enough for all practical purposes.

I also am an amateur, and one who takes no money for photographic work, but freely gives it away, and which I consider I have a perfect right to do.—I am, yours, &c., J. SROBY.

October 28, 1889.

Exchange Column.

Would exchange Dallmeyer's 2s for twelve-inch studio or view camera.—Address FRANZ BAUM, Manchester.

Wanted, whole-plate lens by good maker; exchange, genuine Spanish guitar.—Address, CHARLES JOHNSON, High-street, Wincanton.

Will exchange whole-plate Universal studio camera with lens by Watson, also fifteen and a half inch burnisher; wanted, outdoor set with rapid rectilinear lens.—Address, R. CARTWRIGHT, Photographer, Brighton.

Books on photography (for amateurs), treating of exposing, developing, printing, toning, &c., also a few cabinet photographs, in exchange for fireworks or Godeve's *Mechanics*.—Address, J. R. RIGBY, Howick House, Burscough, near Ormskirk.

Answers to Correspondents.

PARTICK.—The suggestions are receiving consideration.

J. H. W.—1. Apply to Messrs. Marion & Co., Soho-square.—2. Liesegang, Dusseldorf.

REGULAR READER has omitted to send name or address. If he writes again he must repeat his query.

A. H. C. CORDER.—See in "Our Editorial Table" in this number an account of a lantern having the rolling curtain effect desired.

E. G. REYNOLDS.—The lithographs of watering-places got up in the style of photographs may be obtained wholesale from most of the fancy warehouses in the City.

R. CARTWRIGHT.—If your former exchange did not appear it was probably because it was unsuited for that column or not constructed in accordance with published instructions.

J. COOK.—Probably if the positive be varnished and dried by heat its transparency will be restored. The best method of obtaining copies from it will be to print as from a negative.

A. M. W.—Walery, Regent-street; Faulkner, Baker-street; and Tunny, Edinburgh, will make a reduction from your negative and produce a coloured enamel picture suitable for a finger ring.

W. H. J. (Leeds).—Send on one or two of the negatives. From the description, we cannot suggest the cause of failure. The plates are in high repute, and we can scarcely imagine that the fault is due to them.

INQUIRER.—Celluloid and ivory are two distinct materials. The former is a compound of xylidine and camphor, and the latter one of gelatine and a white pigment. One swells and expands in water and the other is unaffected by it.

A. GARDNER.—A wide-angle lens, by reason of its small aperture, is not suitable for instantaneous street views. A quicker lens than this is necessary, such as those of the "rapid" type. Remember the light is much slower now than it was three months back, also that London is not Hastings for light.

SIGMA.—1. For enamelling collodion, methylated alcohol will do quite as well as pure, provided its strength is sufficient. Usually the methylated spirit of commerce is too weak. The specific gravity ought not to be less than .820 to make a really good collodion.—2. All dealers in photographic material will supply pyroxyline.

CANARY BIRD.—It is certainly possible, and quite easy, to get a lens of six inches focus which will give sharpness of everything beyond thirty feet when worked with an aperture of $f/10$. It may be difficult to do so with a larger aperture. To reduce this distance to twenty feet, $f/15$ will be requisite. We could not say more unless we had your lens for examination.

A. has two vats, one for fixing and the other for print washings, but by some means the old fixing baths and print washings have become mixed. He would be glad to know how to proceed to precipitate the same.—Sulphide of potassium (liver of sulphur) must be employed. This will throw down the silver as sulphide of silver. See the recent articles on *Economy in the Printing Room*.

PERPLEXINUS.—The best artificial light for portraiture undoubtedly is the electric arc. We imagine this is available in your town. Next to this is magnesium. So much on this subject appeared in our last volume that we cannot do better than refer you to what is there written. However, if you can secure a supply of electricity, nothing is equal to it for commercial photography.

A. H. R.—It seems to us that the centre of your flame is not quite opposite the centre of the condenser. Measure, and ascertain if this is the case. To test whether the lantern is otherwise right, make use of a candle instead of the regular lamp, and move it up and down, to and fro, until a uniform disc is obtained, no matter how feebly lighted it may be. If you cannot get this, then is there something optically wrong.

W. asks the following questions: "1. Kindly inform me if operators in the best-class studios wear aprons when operating. 2. Also kindly tell me what is the best colour and spotting medium to work up a portrait on albumenised paper?"—So far as we are aware, operators in first-class studios do not wear aprons; certainly they do not when attending upon sitters, as then they are usually in the most *recherche* attire. They may don an apron when in the dark room to save their clothes, but they discard it when in the studio. One gentleman we know of who was in practice some years ago always received and posed his sitters in white kid gloves.

SPOTS writes: "I should feel greatly obliged if you could tell me the cause of spots on the two enclosed pieces of prints—the white spots on the gentleman and the dark spots on the lady. I have seen the dark spots when the prints have been in the toning, or else I should have thought it was something to do with the fixing. A trace of the dark specks can be seen over the gentleman's head."—The spots appear to be due to particles of foreign matter in contact with the surface of the paper. Probably floating particles of pernicious matter from the workrooms have settled on the paper at some stage of the operations—possibly while the paper was drying after sensitising.

ARTIST says: "1. I have got a large number of photographs (landscapes) to colour in water colours, and I find that after the colours dry they are, of course, exceedingly dull, and thus spoiling their beauty. What is used to get the gloss upon the ones I see exposed for sale in the stationers' windows? Are the paints mixed with something (if so, what) before application, or are the prints treated somehow after colouring?—2. My prints (toned to a rich purple) turn brown on immersion in the hypo. What is the cause?"—In reply: 1. Transparent water colours only should be employed, and they should be mixed with gum water.—2. Evidently the prints are over-toned.

B. WOODROW writes as follows: "Would you kindly advise me, through your valuable paper, the best lens for taking a good-size head, say, good cabinet-size vignette? I have a Ross rapid symmetrical and a Vogel cabinet portrait lens; neither of these will take a fair C.D.-V. vignette without distortion. Would a Ross Universal whole-plate take a good-size cabinet head? I have a lens by A. Ross in splendid condition, but it will scarcely cover a quarter-plate, and it is a larger lens than a Ross whole-plate rapid symmetrical."—The diameter of a lens is no criterion of the size picture it will take; that is governed by its focal length. To take a good-size head (cabinet) free from distortion a lens of about fifteen inches focus should be employed. A "Universal" is the best form that can be employed.

A. B. writes: "I should be obliged if you will give me your opinion on the following:—For twelve months I have been using ready-sensitized paper, and in washing prints in five waters before toning the water does not show any silver in it. I have had the first water like milk before this brand, now I do not see the least sign of it. The strangest part is, I have an assistant, and he lives seven miles away, and does work at home, and he gets his paper from the same place, and his always turns the water milky. The water is supplied from the same works. I got him to take six sheets of my paper to try, but with the same result—his water milky, mine not."—Perhaps some correspondent can account for the discrepancy. It does not necessarily follow that because the water may be supplied from the same company that it is delivered in the same condition in different districts.

BEGINNER writes: "I have just taken a studio with the lighting of which I am rather puzzled. Position, running north to south; sides facing east and west: both sides equally available for light; size of studio, twenty-four feet by twelve feet, the whole of which, excepting three feet at each end and the same proportion of sides, is composed of rolled ground glass. I am anxious to know how much and where to block out light (the amount of present light being intolerable), and which side is preferable for lighting the sitter, east or west."—Our correspondent is in possession of a studio which would be the envy of many. In such a studio work of every possible description could be carried out. We should recommend that curtains be fitted so as to cover up the whole of the sides, and blinds to cover the top; then every possible lighting can be obtained. The most convenient way of using the studio for portraiture will be to place the sitter at the south end, and use the west light in the morning and the east in the afternoon. As our correspondent is a novice in photography, it would, perhaps, be well for him to get a few lessons in lighting from a professional photographer.

* * Several articles and letters are unavoidably postponed through want of space.

PHOTOGRAPHIC CLUB.—November 6 will be the annual general meeting.

THE HACKNEY PHOTOGRAPHIC SOCIETY.—On November 14 a paper will be read by Mr. Birt Acres on *Isochromatic Work*, illustrated by the lantern. He will also exhibit his patent developing dish, by means of which the care now needed in developing isochromatic plates is greatly obviated as regards light used.

WORCESTERSHIRE CAMERA CLUB EXHIBITION.—The first Exhibition of photographs, photographic appliances and apparatus, will be held in the Museum and Art Gallery, School of Science and Art, Kidderminster, from March 1 to March 15, 1890. Particulars may be ascertained on application to the Hon. Secretary, Mr. William Ray, School of Science, Kidderminster.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1540. VOL. XXXVI.—NOVEMBER 8, 1889.

NEGLECTED PROCESSES.—GLASS POSITIVES— ALABASTRINE PICTURES.

AMONGST the neglected processes must now be enumerated the glass positive process, and the alabastrine process. In the minds of the majority of modern photographers positive pictures are doubtless associated, solely, with the productions of those itinerant photographers who take portraits on glass, or on japanned sheet iron—ferrotypes—on the beach, or other well-frequented spots. It is true that these are positives, but they are, without exception, nothing more or less than a libel on the process and what it is capable of producing.

A really good glass positive is an exceedingly nice picture, while, for delicacy and fineness of detail, it is unapproached by any other photograph, if we except, perhaps, the Daguerreotype. We well remember, in the early days of collodion photography, the charming glass portraits that were produced by some artists. We have also in our mind, just now, some most excellent stereoscopic pictures by Messrs. Negretti & Zambra of the interior of the Crystal Palace, and views from the grounds—not their transparencies of the same subjects—which were exceedingly beautiful when seen stereoscopically.

At one period the positive process was extensively practised, even by the best photographers, but somehow or other, in a comparatively short time, the pictures came to be looked upon as being of a kind of plebeian character. It almost appeared that the professional, when he became proficient in producing first-class work—for it must be remembered that, as a rule, in the old days of the collodion process, positives were the first things that the beginner essayed—went in for negatives, then he usually considered it *infra dig.* to take a positive picture; hence this branch of collodion photography, as a business, was left entirely in the hands of third or fourth-rate men, possessing little or no skill whatever. It is mainly from this cause that collodion pictures on glass fell into ill-repute—that is, in this country; for in the United States glass pictures, under different names, mainly that of Ambrotypes, attained a higher status and retained it for a much longer time than they did in England. In America greater skill was brought to bear on this class of picture than was ever the case here. It may be mentioned that quite as much, if not more, skill and experience is requisite to produce a positive of the highest order of merit than there is in the production of a first-class negative. And, as we have said before, those who possessed this qualification would not expend it in this direction.

Positives could be coloured, and thus be rendered still more effective. The present idea of a coloured glass picture is generally connected with a little powder colour roughly applied by those who have no artistic knowledge whatever. For ex-

ample, a little red is rubbed on the cheeks, blue on the background, with perhaps some red and yellow on the drapery, and is applied in such a manner that the picture, when finished, looks vulgar in the extreme. But collodion positives could be really well coloured by any one with artistic ability, as they were by many, notably by M. Mansion and others. When thus treated they were exceedingly good and effective pictures. The best class of positives were always varnished, to preserve them. The varnish generally employed was dammar resin, dissolved in benzole or chloroform, and it was applied cold. This varnish did not degrade the whites as a spirit varnish was liable to do. In the early days glass pictures were taken and coloured by some of the then leading houses, and were charged at a very remunerative rate, the prices being often reckoned by guineas.

The term "alabastrine pictures" will no doubt sound novel to many, but it will be perfectly familiar to all our older readers. These pictures were essentially collodion positives, whitened by bichloride of mercury. The peculiarity about them was their extreme delicacy, and the pearly-like whiteness of the lights. This quality rendered them especially suitable for tinting, and the surface of the film lent itself particularly to the reception of the colour.

The process was this:—A positive was made in the ordinary manner. It was then treated with the alabastrine solution, which converted the image into one of pearly whiteness. The solution was a commercial article, and its preparation was long kept as a trade secret, although we are aware it has since been published. It is well understood to be a solution of bichloride of mercury strongly acidified with both nitric and hydrochloric acids, and containing a certain proportion of alcohol. Positives, when treated with this solution, become beautifully white, and are quite free from the blueness conferred by the use of a plain solution of the bichloride. With the commercial preparation was sold a so-called "penetrating varnish," also a secret preparation. This, when applied to the tinted picture, caused the colour to show through on the glass side, which gave a very pleasing effect; furthermore, it permitted of non-reversed coloured pictures to be produced. A dammar varnish here answered very well.

Although collodion positives could be finished off, and be ready for delivery within a few minutes from the time of their exposure, they must, if varnished, be classed amongst the most permanent of all silver pictures.

Gelatine is not so well suited for glass positives as collodion, the difficulty being in obtaining purity in the whites. Ferrotypes plates, however, prepared with gelatino-bromide of silver, were introduced some time ago, but we believe they did not

meet with much success, principally for the reason just mentioned. There is very little doubt, if dry plates were placed in the market which would yield positive pictures such as those obtainable on collodion, that they would command a ready sale.

AMATEUR DARK-ROOM APPLIANCES.

No. II.

AFTER the lighting, the most important item in the dark room is, perhaps, the water arrangements, and here, as a rule, the amateur finds greater difficulties standing in the way of his comfort and convenience than in any other department. It is not a great hardship, perhaps, to have to convey a can of water into the dark room before commencing developing operations, and to use it from a jug is not much more trouble than from a tap; it is not difficult either to provide a suitable receptacle for the waste; but the necessity is always present, failing a properly fitted sink with supply tap and waste pipe, of providing for the disposal of the waste and generally clearing up every time the dark room is used. The amateur who rejoices in the possession of a fully equipped dark room, with laboratory conveniences, enjoys luxuries which too many are strangers to, and only those who have experienced it know what a constant nuisance makeshift contrivances are, and how persistently, just at an awkward moment—when all attention is required in some other direction—it is found absolutely necessary to empty the waste vessel or replenish the supply.

Where a bath room or lavatory is available, such will always be utilised, if at all possible, on account of the convenience of fixed water arrangements; and as such rooms are usually or frequently provided with windows smaller than those of ordinary apartments, they are specially adapted to the purposes of a temporary dark room. But if circumstances prevent, then there is nothing for it but to make the best arrangements possible. We shall presume, then, that no fitted water supply is available.

Many of our readers, no doubt, have experienced, before the days of public dark rooms at hotels, the "pleasure" of developing in the bedroom, with the aid only of the ordinary toilet conveniences, supplemented perhaps by an extra can of water supplied by an obliging chamber-maid. Such conveniences are, perhaps, to be tolerated as a matter of "Hobson's Choice" when travelling, but how often is it found that the water supply is in excess of the facilities for disposal of the waste? and how often is it discovered in the middle of the development of a plate that all the available waste receptacles are full, and there is no means of washing the plate? Unhappy, indeed, is he who is compelled to rely on such "conveniences" at home; but we fear there are many so situated, merely for lack of a little energy or ingenuity.

If it be a matter of compulsion to work in this manner, it should be at least arranged that the receptacle for waste is of ampler capacity than the supply vessel. Then the failure of the supply is the signal that in replenishing the latter it is time to empty the waste, and if it be made a matter of invariable duty to perform both operations at once much trouble and mess will be saved.

But at the best of times the ordinary toilet basin forms a most inconvenient "sink" for developing. Its capacity is not great, and it is difficult to pour from when it gets nearly full, so that constant "slopping" is the almost invariable result. Even if a circular basin, fitted with a plug and waste pipe, be

substituted, the shape is against it, especially when the plates are anything larger than half-plate; still, for the smaller sizes such an arrangement may be made to answer. The small japanned metal washstands, now so common, consisting of stand fitted with basin, and waste pipe, and platform below for slop jar, supply an inexpensive and not very bulky arrangement, that may be made a permanent arrangement for the special purpose of development; but, as we have already said, the circular basin is inconvenient, and not to be compared to a sink of proper shape and dimensions.

The Doulton-ware sinks, obtainable in all sizes and at moderate prices, are better in respect of shape, but they are heavy and clumsy, and necessitate a fixed position for the developing table. They are, moreover, as a rule, too shallow to prevent splashing unless great care is exercised; and, lastly, from their material are apt to lead to frequent breakages. A lead-lined tray or sink is an improvement, but these are both expensive and weighty, still they need not prove unduly so. The best arrangement, without exception, for the amateur is a plain wooden sink constructed as we shall describe.

We may, first of all, speak, however, of the general arrangement, which we will call the developing table, and which, without occupying a great deal of space, may be retained for its special purpose even in an ordinary bedroom. The table may, of course, be specially constructed, and made to close up like a folding washstand, in which case it will not only be self-containing, but, when not in use, may serve the purpose of a side table or even dressing table. But the arrangement we have to describe is of a simpler and less costly character.

It consists mainly of one of the cheap washstands, procurable in all sizes, from about two feet in width, in painted deal, at a cost of a very few shillings. In addition to the table, with or without a circular aperture for the basin, there is usually a platform a few inches from the floor, but this is not absolutely necessary, though it is convenient. In selecting such a piece of furniture, let one be chosen not less than thirty inches wide (three feet will be better), and commence by cutting a square or oblong aperture on the table a few inches smaller each way than the size it is intended to have the sink. The latter is then fixed beneath the table by means of screws, in addition to a couple of fillets of wood fixed to the legs for it to rest on. The sink must be perforated for a waste pipe, and an ordinary galvanised household pail of large size—say, to hold four gallons—placed on the lower platform will complete the arrangement so far as the water is concerned.

If canvas or some cheap ornamental material be nailed round three sides, and a curtain of the same provided for the front, the lower platform may be utilised for a variety of purposes—as, for instance, in storing away bottles and dishes when not in use, or it will form a convenient place for the fixing and alum baths, and for the washing rack when at work. The whole, when so arranged, will form a not unsightly adjunct to the room, and, if fitted with a removeable top to cover the sink, may be utilised for other purposes when not required for its legitimate one.

We now come to the construction of the sink, which is to be, as we have said, of wood. Many useful water-containing vessels are constructed of wood simply, without any lining whatever, but in order to be water-tight they must be not only well put together, but must be kept constantly in use, or nearly so; for their staunchness depends upon the wet and swollen state of the material. If this becomes dry it shrinks, and the joints at once commence to leak, if they do not actually develop fissures.

We do not, however, propose to rely upon either of these conditions for the efficiency of our sink. Good workmanship is never wasted, but in this case there is no necessity for dovetailing or "tonguing and grooving" the body of the sink together, though the latter, of course, makes a better job of it. Let the wood be one-inch deal, carefully planed, at least one side. Cut it up to dimensions, taking care that all the edges are carefully and truly squared up, and put it together with stout screws. It is screwed together first of all merely to fix the positions of the various parts.

Next procure some white lead ground in oil, and mix with it, carefully and thoroughly, about one-fourth its weight of dry red lead until it is of the consistency of putty. This being ready, unscrew the woodwork, and with a putty or palette knife spread a layer of the mixture over the joints of the sides to the depth of an eighth of an inch, and then screw them tightly together so as to squeeze out as much as possible of the lead. The bottom now remains to be put in, and this will present a little greater difficulty, as it is nearly certain to be in at least two pieces. If so, and the joints are tongued, thin down a little of the lead with turps to the consistency of cream, and apply this freely to both tongue and groove, bringing the two pieces together with as much pressure as possible. If a pair of carpenter's cramps are available so much the better. Finally, put in the bottom in the same manner as the sides were put together, screwing up as tightly as possible; or one section of the bottom may be put in first, followed by the other or others, trusting to the screwing up to make the joint good. It will be easy to find the screw holes with the points of the screws, and as these are worked home they will gradually force the two pieces into contact. If the joints be not tongued, but square, the thick lead must be used.

We have now a framework solidly screwed together, and with its joints filled in with a waterproof composition which will gradually harden and cement the woodwork tightly together. But to make assurance doubly sure, and fill up any chance interstices, that may occur, we take some of the lead thinned down with turps and paint over all the joints, inside and out, and then let the whole dry.

While the drying is taking place we may proceed to arrange for the waste pipe. If preferred, an ordinary brass plug and furniture may be let into the bottom, and a lead pipe soldered, or a short length of rubber hose attached by means of wire at the reverse side, but we prefer the following plan as making a better job:—Commence with a centrebit to bore a hole an inch and a quarter, or an inch and a half, in diameter, and when a depth of three-eighths or half an inch is reached, change the bit for one of an inch and finish. This will furnish a hole with a shoulder or rebate.

Next, get a plumber to supply an eight-inch length of one-inch lead pipe, with a flange or washer of stout sheet lead, three inches in diameter, soldered on to it at right angles to its length, and about two or two and a half inches from one end. Insert the shorter length of pipe into the hole in the sink from the outside, and fix it firmly in position by means of three or four screws. Turn the sink over and measure off as much of the projecting pipe as will a little more than reach to the edge of the recess or larger hole in the wood when bent over, and cut the pipe at that point. With a plumber's "turn-pin"—a conical piece of hard wood—or with the nose of a small hammer, gradually beat out the projecting pipe until it is turned over in all directions, and lies down in the recess left in the wood, which should first be packed with the red lead to make

it water-tight, and when completely in contact scrape or pare the pipe down to make a neat funnel-shaped aperture. This makes one of the most satisfactory joints at a merely nominal cost.

When the red lead is dry, which may be expected to occupy a day or two at least, the sink is finished by giving it one or two coats of ordinary Brunswick black, allowing the first to dry thoroughly before applying the second, and it will be improved if exposed to sunshine for a day or two to harden the asphaltum. That done, the sink is ready to fix in position.

Although described as a "makeshift," this is really not so, but a thoroughly durable and efficient contrivance that can be constructed at a very moderate cost. We have had one in use for some years that had no more elaboration in its construction than we have described, and it would have been as efficient now as when newly made, without any further care, had we not, in an evil moment, decided to renovate it. Preparatory to re-blackening it, it was placed in the open air to dry, and unfortunately the sun got to it, with the result that the wood shrunk and "let daylight through" the joints.

As the simplest way of remedying the defect, after vainly endeavouring to re-caulk the seams, we adopted the following plan, which we recommend to those who would in the first instance avoid such a mishap. Having procured some "lead foil," which is really thin sheet lead, we re-blackened the wood, and while it was still "tacky" laid the lead carefully down on the bottom, and turned up half an inch round the sides, using a hot iron to smooth it into contact, and by melting the asphaltum make it adhere. The sides were then covered in the same manner, and we now have practically a lead-lined sink. The foil is obtainable, we imagine, at any lead merchant's, but Harrison's in Drury-lane supply it in sheets about 28 x 14 inches, weighing about one pound or a little less, and costing a shilling a pound.

Portable dark rooms will form the theme for our next chapter.

WE are glad to learn that some friction—the result of misunderstanding—which has lately existed between the two past-Presidents of the Photographic Convention, Mr. Andrew Pringle and Mr. J. Traill Taylor, has been assuaged—the hatchet has been buried, and the *entente cordiale* once more established. It only needed that they should discuss their differences quietly and dispassionately to ensure the descent of the Angel of Peace. *Appropos* of the Convention, we have received a letter from Chester, from which we are pleased to perceive that the photographers and friends in that quaint old city are already making such arrangements as will ensure the next year's meeting being a most enjoyable one.

THERE is no reason why an ordinary camera and lens should not be employed for photographing the moon; the image obtained would be very minute, but, enlarged to a size within the bounds of practical photography, a representation of the orb sufficiently interesting to be worthy of preservation and reference, if not of great scientific value, might be obtained. Any one who knows—as all ought to do—the focus of his lens can ascertain the size of the image it will give by a simple calculation. Let us take an example to elucidate this fully. Most photographers who work up to 12 x 10 plates possess a portable symmetrical of at least twelve inches focus; if this be unscrewed and the back lens removed (a plan which, for the purpose in view, will be preferable even to using the back lens alone *in situ*), he then has a lens of, roughly speaking, twenty-four inches focus. If now we multiply this twenty-four by nine, and divide by 1000, we obtain the size in fractions of an inch of the moon's image obtainable by the lens. In this case it would be $24 \times 9 = 156$; $156 \div 1000 = .156$, or about one-seventh of an inch, as the size of the picture of the moon this lens

would give. It is a very common thing to enlarge a head one inch in diameter to life size with extremely sharp results. This is seven or eight diameters, and the small moon negative enlarged on a similar scale would give us pictures one inch in diameter.

THE moon being so bright, the exposure of the original negative might be sufficiently nearly instantaneous to prevent any possibility of blurring through the earth's motion, and again, by taking certain precautions, two negatives might be taken which would give stereoscopic effect.

ATTENTION has again been called to Japanese varnish materials. A near inspection of even the cheapest of the varnished or lacquered goods that come to us from that country serves to show that its craftsmen must be in possession of some serviceable substance procurable at an exceedingly cheap rate for this class of work. Mr. R. Hitchcock lately read before the Chemical Society of Washington an account of the source of the resinous basis of Japanese lacquer. It is the product of a tree that grows to a considerable size and lives for nearly half a century, but useful for lacquer production only in its younger stages. The lacquer is obtained year by year, and, finally, the tree is cut down and the substance extracted from its branches. Mr. Hitchcock urges that greater attention should be given to it than has yet been the case, and from his information it is evident that it would be an invaluable addition to the resources of the photographic manufacturer. "It gives a surface to wood much harder than our best copal varnish, without brittleness. It takes a polish not to be excelled, which lasts for centuries, as we may see in the old treasures of Japan. It is proof against boiling water, and, indeed, it seems to be insoluble in every agent known. It is the best possible application for laboratory tables. I have a set of photographers' developing trays that have been in use for more than a year, and I find them excellent and cheap." This is the report of Mr. Hitchcock, and it surely calls for a really close investigation into the properties of such an agent as he describes; as for baths, trays, and sinks, its use would be simply invaluable in photographic work.

THIS agent appears to have only one drawback: it is poisonous in the fresh state—a quality, however, which would have little concern with its employment by photographers; they are familiar enough with the handling of poisons.

ACCORDING to the *Novoe Vremya*, as quoted in *Nature*, the carrier pigeon has been turned to a curious use in Russia. It is to convey negatives of photographs taken in a balloon. The first experiment was made from the cupola of the Cathedral of Isaac, and the subject photographed was the Winter Palace. "The plates were packed in envelopes impenetrable to light, and then tied to the feet of the pigeon, who safely and quickly carried them to the station at Volkovo." So we are told; but there is an extensive hiatus in the account. The wonderful material on which the negatives were taken is not stated, nor the mode of preserving from light; nor how this is proposed to be arranged in a balloon, nor the distance of the bird's flight. This is all a very different affair from the Paris Pigeon Post, the messages in which were photographed by collodion on glass, which was afterwards peeled from its support and enclosed in a packet attached to, not the bird's feet, but a tail feather. Seeing that about fifteen grains is looked upon as a practical weight for a bird to carry, it would appear that very little negative and light-tight wrapping could be included in the weight, which does not include much in the shape, for example, of thin paper, seeing that even so slight an object as a five-pound (or any other) bank-note weighs more than that amount.

So far photographers have not gained much from the improvements in, and the cheapening in the manufacture of, aluminium; yet there are few cases where the metal could be introduced with greater advantage—lenses and cameras, not to speak of numerous machines and mechanical appliances, could all be practically improved by the adoption of this metal, or of a bronze obtained by its aid. We should, however, expect that its introduction is only a question of

time, as the papers read at the British Association meeting by Professor P. P. Bedson, D.Sc., on the one hand, and Mr. J. H. J. Dagger, F.I.C., on the other, show the great industrial importance the works erected for its manufacture already possess. The former *savant* describes the metallurgical process adopted at Wallsend, and the latter the electrical process in use at Milton, in Staffordshire, and from their accounts we learn that a large industry is already started.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

No. VI.

F. H. EVANS (Nos. 435 and 446).—Two frames of portraits containing some very good work. The photographs are only quarter-plate size, but display an aptitude for the realisation of character which is worthy of being especially alluded to. Two matters are deserving of attention: one, the introduction of moderately dark backgrounds, which throw the attention direct to the portrait, the lighting of which is also well managed; the other matter is, that apparently they have not been subjected to the ruinous retoucher, as many lines on the faces testify. Altogether, these are a very unaffected example of photographic portraiture.

F. Downer (No. 454), *Lady Edith Villiers*.—Portrait of a very young lady, where the position is effective, being simply the realisation of a perfectly natural position, which, although involving the necessity of each side of the figure and dress being identical, is nevertheless in harmony with the character of the sitter. There is a calm repose and dignity about this portrait which makes it very effective.

Mr. and Mrs. W. J. Anckorn (No. 435), *Saturday Night*.—Another of those realistic pictures where children are portrayed in a necessary domestic occurrence, in the house, possibly, of the working classes, being nothing more than the Saturday night's washing. Alas! that photography should be just as capable of accurately depicting the commonplace as it can be exalted with all the glamour of that accurate detail which to many appears to be the only reason for perpetuating such a subject.

G. Balfour (No. 490).—The head alone of a boy, noticed just to point out the singular effect produced by the chin being almost at the lower part of the photograph, suggesting the possibility that sooner or later this dark boy will descend right out of the frame.

Lient. R. C. T. Blunt, R.N. (No. 518), *Under the Olive Tree*.—The executive part of this photograph is very good, and well chosen for pretty detail: a little girl in white has been arranged to be effective, but the scene is so quiet that solitude would have enhanced the effect.

Valentine Blanchard (No. 525 and three other frames).—Containing small views in the Isle of Wight, being a departure from the usual figure-subjects which we look for from this exhibitor.

Rev. F. C. Lambert (No. 531).—A study of a seafaring man, *Waiting for the Signal*, who has been carefully arranged, but the repetition of some straight lines in the material of the background considerable interferes with the repose which is suggested by the title.

Mr. J. Harding (No. 542), *Evening Pastime*.—Some rustic cottagers at their door; the daughter sitting on the ground, reading a book, is rather awkward in position, which might have been more effectively arranged if her dress had been carried out to the left of the picture.

Anselm Schmitz (No. 546).—A frame of thirty-five views, very dark in treatment, and not in concord with the large work of the same exhibitor, which we shall notice in due course.

J. C. Andreae (No. 549).—A series of small views with figures, which are rather dark in some parts, and, as a whole, not up to the usual specimens of this exhibitor (who makes his own plates). The figures, of which there are many, in many instances have been more carefully attended to than in previous exhibits.

S. Glen Payne (No. 555).—This is one out of three pictures by this exhibitor, who has done better work in the past. It is a very pretty study of trees on the Chilterns, but there are too many dark portions, which should have had better treatment from the scientific aspect.

The Misses Mead (No. 562).—This is the best work out of six other

pictures which these ladies have done. This particular specimen is exceedingly good, both in choice of subject and treatment of the negative. It is a most effective "bit" of English trees and foliage, which promises well for some future work.

Mrs. Main (No. 565).—Two bits of Swiss mountains, most carefully manipulated. Success in such studies can only arise out of very careful attention to the treatment, which these views have evidently received. There are two other frames of bits in the same locality by this lady, whose present exhibits are in considerable advance of previous work, and show much daring in the study of such cold but grand mountainous scenes.

Mrs. E. Penton (Nos. 567 and 568).—Two enlargements from small negatives by the exhibitor, who shows a capacity for pictorial effects which will become increased in power by future study. One photograph is a fisherman, the other a fishwife; and although the positions are possibly those of the persons themselves, it is evident that care and appreciation of the result has guided the point of view.

J. J. Acworth (Nos. 582 and 583).—Two frames, each containing eleven small studies of views in Italy; and No. 586, three views in Nuremberg. Some very good, although small, photographs of picturesque spots, very nicely manipulated; but there is one matter which disturbs the enjoyment of these scenes, and that is the blue-grey colour of the mounts and the white edges of the openings; these coming into the vision produce a disturbing effect, which is not doing justice to the photograph. We dwell upon this matter because there is much wrong done in this direction.

H. G. Peabody (No. 591 and three following pictures).—Contains some exceedingly good manipulative work of sea and yacht studies; and here, again, the colour of the photographs and that of the mounts are not in harmony. Once more the disturbing power of these matters pains the vision, and one cannot look at such a combination of opposing forces without a shudder.

Alfred Stieglitz (No. 598).—A scene by a foreign photographer, where some country children are enjoying the ceremony of being photographed; also No. 599—a little maid at the sea, stooping down to fill a vessel. These pictures are very small, yet they both give evidence of an appreciation of character which will show good results in the future.

W. J. Byrne (No. 602). *The Emperor of Germany*.—There are six photographs of the Emperor in one frame, and we notice this simply to remark what a singular effect is produced by the mixing together of portraits of one person only. We also think that it is not possible under such circumstances to produce results which are worthy of being exhibited. These subjects require a larger amount of thought and design than can be given on such occasions, and hence the conclusion arrived at is that it would have been prudent to have kept these results in retirement.

Fred. Downer (No. 636).—Six rather large portraits in one frame. These prints are fastened on to folded fabric, which is very unsuitable for exhibition. However, some of the photographs show very good work, but the eccentricities of costume will often stop the way for pictorial advance.

Anselm Schmitz (No. 638), *Staircase, Royal Castle, Cologne*.—To this picture has been attached the word "medal," in conjunction with No. 129. This exhibit is a very large photograph, being 40×32 inches, and is full of very fine work, the original being constructed of marble figures, columns, and ornamental detail, the whole of which has been exceedingly well managed. A staircase covered with some dark fabric helps the general arrangement for light and shade, and the whole is a triumph of optical and chemical study, which has resulted in a production which nothing but photography alone could have produced. The same remark will apply to No. 129.

F. Muller (No. 635), *Portrait*.—This is one of many others exhibited where the frame has been made as large as possible, overwhelming the subject-matter; head about five inches in height, and dwarfing the importance of the photograph, which is very nicely treated, but somewhat too dark in general.

S. R. Brewerton (No. 96).—Out of several other photographs by this exhibitor this is decidedly the best. There has been thought exercised in the selection of the subject and the figures, the result being a very good example of careful work.

Fred. Beasley (Nos. 132 and 133).—Two pictures which show a

departure from the usual work of this exhibitor, who now leans towards the picturesque with rustic figures. These, not requiring training, are so handy for the living accessories which now pervade the detailed scenes so attractive to the photographer.

E. A. Perkins (No. 192 and two frames of similar subjects, each having three 15×12 photographs in them).—All these are very similar in construction, and hence these exhibits show the dawning of a better time, when a little more freedom in the arrangement of the subject-matter, aided by such good scientific treatment, will result in some very good work.

F. Muller (No. 196), *Portrait direct*.—This head is smaller than life-size, and has been well arranged for effect, possibly a little deeper in tone than many of our English photographs, but having a larger range of tones, and consequently greater rotundity in the modelling. This is a quality which much of our own portrait work is deficient in.

Thomas Protheroe (No. 362).—A frame containing six 16×11 portraits, showing an onward movement in natural posing, which is also increased in value by light draperies being most carefully manipulated, resulting in detail combined with softness.

W. J. Byrne (Nos. 374 and 375).—Two subject pictures. An endeavour to realise the difference between a town and village artist, who are both making pictures from girl models. The subjects are very good, but the posing is somewhat artificial—a little too much like portrait work. The best is that of the village artist, but it loses its effect by the three figures (two girls and a boy) having been placed too symmetrical, namely, one in the centre and one at an equal distance right and left.

R. S. Redfield (No. 384).—There are several other small studies, but the best is a frame of two pictures—a little girl in one eating, in the other drinking. Rather unpoetic subjects, yet at the same time very simple and perfectly natural in action, which is very pleasing in the result.

J. Chester Jarvis (No. 397), *Un Militaire en retraite*.—A foreign scene, where a supposed sportsman is marching on with a hare or rabbit dangling in his hand. There are three other photographs, containing domestic figures. All these pictures show a decided advance upon former exhibits, only it is unwise to make the same building do duty for three out of the four backgrounds.

Gunn & Stewart (No. 404).—A frame of ten children very carefully manipulated, showing great attention having been given to the lighting, the result being that the faces become the most prominent part of the photographs; and the same results have also attended No. 624, a frame of ten ladies 12×10, partaking of the same well-directed care and workmanship. Another single picture, No. 9, *Baby*, in platinum, 24×18, is an exceedingly good photograph, where the position and treatment of the very young lady is also marked with very good qualities.

Lyonel Clark (No. 409 and two other portraits).—Evidently treated with a view to produce an effect unlike other photographs, the result being somewhat like copies from paintings where the colours have come out too dark.

J. M. Nisbett (No. 456), *The Great Strike*.—A very good photograph, conveying an accurate memento of the Dock Strikers in their daily march, and which contains a large amount of their curious personality.

V. H. Chintamon (No. 513).—An enlargement, about four feet high, of the Maharaja of Bhownager, G.C.S.I. A full-length figure, very carefully treated for position, but which has received much brush work, although the original negative must have been good.

The Autotype Company (No. 436), *A Lion*.—A very fine enlargement from the original negative by Gambier Bolton, which has been already noticed; this picture possesses the good quality of being seen at its best from a distant point of view, and is an exceedingly fine specimen of all the best qualities of an autotype enlargement.

THE WHOLE DUTY OF THE PHOTOGRAPHER.

No. V.

WITH these words I thought to conclude this little series of "*Obiter Dicta*" * (especially *Obiter*, many will think), but certain matters

* An "*Obiter Dictum*" is defined by the author of that delightful little book to be an extraneous or impertinent opinion expressed by a witness in the course of evidence.

which have lately come under my notice seem to call very urgently for a few condemnatory remarks.

Firstly and chiefly, the ways of the retoucher. That destroyer of beauty is a product very natural to this time and country, where there seems to be no higher ideal of art or beauty among the people than a mechanical smoothness and perfection of detail, technical quality in short, as distinguished from artistic merit. This is well shown in casts from fine antique models. It is generally known that many people prefer casts with the lines of the mould left untouched; and very rightly, for though these sharp, ragged lines are a serious blemish, they are far preferable to the entire destruction which would be wrought by the workman in removing them. The ordinary method of finishing a cast after it leaves the mould is to pass a wet sponge over the whole surface; this, done by a skilful hand, accomplishes its end to perfection, and produces a most perfect smooth surface, but at the cost of completely sacrificing all the subtle delicacy of line which distinguishes the work of the great artist from the product of mere mediocrity. What wonder then that any one who has an eye for the value of the original design prefers to have a faithful copy with all the imperfections of mould lines and rough surface rather than the same "improved" by the British workman? This same base ideal of mechanical perfection is found in every product of industry in this country. We make very fine engines and tools, probably as good as they can be made in the present state of knowledge, for here the mechanical ideal is the true one, and there is no higher. But whether we be a nation of shopkeepers or no, we are certainly a nation of engineers, and we manufacture nearly everything on the same principle that we build machines; witness these casts from the antique models I have mentioned.

Proof upon proof of this assertion is to be found wherever we turn, but perhaps the results of this low ideal are more obtrusively abominable in the case of photography than in any other art or craft. The destroyer whom I wish especially to anathematise at present is the reckless retoucher. A few instances from a multitude will best show what sort of work this enemy of mankind has been doing.

I saw a panel portrait, by one of the best London photographers, taken from an original certainly not deficient in good looks. The face of this sitter, however, was not to the retoucher's mind, so he got his tools about him and went to work, and I have no doubt looked on the result with triumph. Said result represents a face apparently very skilfully moulded in dough which had run a little in the baking. It is smooth, characterless, idiotic, and the eyebrows and eyelashes have disappeared in the course of the improvements! I tell a plain, unvarnished tale; the thing is as I say. The portrait of the dress is good, and that was the principal object, or the photograph would have been rejected. Other portraits I see every day which have the same sort of resemblance to the originals that a corpse has to the living, breathing human being; the features are usually left almost unchanged, but all the life and character are gone. Would we not rather have portraits which would really show us what our friends look like, than these smoothly finished products of retouching, though the complexion was not so perfect, and might even appear freckled? Surely we would, those of us who have eyes to see, but I know only too well that we are a minority; the retoucher has educated the public taste down to his own level, and the majority now expect and demand the products of his handiwork. But it is assuredly true that photography can never take its right place in the world of art as long as the retoucher is allowed to lay his dirty fingers on all the finest work of the lens.

To bring about any change for the better would, I know, be a difficult matter. It has often been said that when a man starts on the downward course he finds the rails have been well greased for the occasion, to which is added that if he wishes to reform and climb up again, he discovers that the same kind friend has once more made his foothold slippery. The same is true of classes as of individuals. Portrait photography is in a bad way at present: how may it be improved? This would appear to me to need much of the wisdom of the serpent as well as the gentleness of the dove; for how is a professional to know whether a particular sitter wants a real portrait or the thing the retoucher makes? This can only be found out by acuteness and careful questioning, for most people would say they did not wish to be retouched, but many of them would be highly disgusted with the result. Some there are, however, and I believe more than we might think, who would pardon some roughness and technical defects in order to have portraits satisfactory to the eye of the artist.

To be just to the wretched creature, the retoucher has a function, a small and humble one, and he is far from being a humble person; he thinks no small beer of himself, and will by no means remain in his proper sphere; and this is the reason why my soul craves for a revolver and a bowie knife wherewith to enter upon a new crusade and wipe out the whole fraternity.

There is a lower depth than this. We stand in a wilderness of ugliness, crying out to all who may hear, "Give us beauty, surround our lives with things fair to see," and in answer to our wild appeal comes the new prophet of commercialism with his fixed shopkeeper's smile, and recommends "his new series of studio boulders in eight pieces, price sixteen shillings, defying competition." Did ever any one hear of such a grim travesty of nature as a stuffed boulder? Yet this is not a joke, for I received quite an elegant little circular from a very well-known firm of photographic providers, setting forth the excellent qualities of their stuffed boulders, with two engravings representing the said strange fabrications to be nearly as ugly as I have no doubt they are in reality. These things are, no doubt, lineally descended from the monumental pillar which held its place in all studios so much too long. The pillar had a function in its young days when exposures were long and head-rests not invented, but what can be the use of stuffed boulders?

Blind leaders of the blind! do you conceive that you can imitate the works of nature, and with your tools and low cunning make to yourselves representations of the products of frost and flood, fashioned and polished by streams and waves in ages of patient labour?

COSMO I. BURTON.

COLOURED PHOTOGRAPHS.

XII.

I FEEL sure there were many who, having read these papers regularly, murmured a gentle prayer of thankfulness that the analysis of the various colours had at last come to an end. Well, believe me, I can heartily join them, as there is nothing more tedious than writing or reading such matter. Still, however, I think it will, at least, be no disadvantage to know a little about the colours we are about to use in painting photographs. I am writing these papers with a double purpose; to show some of the best methods of colouring photographs, and also to prove that an artist who is thoroughly master of his art can paint a portrait upon a photographic base which may, undoubtedly, be looked upon as a work of art. I presume, naturally, that the qualities which mostly tend to constitute that most debatable of objects, a work of art, is *faithfulness* in representing nature in its true colours, and *style* in carrying it out. Without these two qualities, I take it, we are abroad in terming any picture a work of art. There are few, it is to be hoped, who will hold that a fair drawing decently coloured, although presumably a work of art, is entitled to be so described.

To any one who has never made a study of colouring, and who knows little or nothing about the relative values of colours, the difficulty of painting a head from life must appear almost insurmountable. Of course, if to this be added the incapacity to *draw*, we should only expect a dismal failure; and I think, in this regard, we would be more fortunate than most people in this world—we *would get what we expected*.

From this it may be gleaned that *drawing* is the first branch of art to be acquired, as without the power to depict faithfully the *shape* and various markings of a head, it will be useless proceeding further with our picture. We will assume that this knowledge, together with a keen appreciation of the value of light and shade, has been acquired, and to such may be left the option of accepting the help of photography or not. I can assure my readers that the number of artists of the first standing at the present day, who call in the aid of photography from time to time, would astonish the uninitiated. There are many who have a strong sense of the relative values of colours, and who possess a very striking style of placing same on a canvas, and who are yet unable to make a faithful drawing of the object, or subject (perhaps this is better), before them. To such, what a boon is photography!

We will, for our present purpose, assume that we are fairly gifted, and know a little of what we are doing. Let it even be conceded that we can paint from nature, but find ourselves obliged to paint upon a photographic base. It may also be as well to restrict ourselves to *water colours* in the first instance; we can afterwards take *oils*. Now suppose we have a vignette head and bust to colour; we must first *prepare* the paper, before starting colouring, in such manner as may be best for the various surfaces upon which photographic images are sent to artists. In this we can use either the preparations made by Newman or make substitutes ourselves, which will suit the purpose fairly well. This done, we will go ahead.

In painting a portrait, be it either a head and shoulders vignettised or an ordinary *printed-out* background, *three sittings* used to be considered sufficient in most cases; but, needless to say, some artists,

although men of the highest and most undoubted talent, required more. Indeed, there are cases on record where the artist has had more than forty sittings. Now, in the case of photography, *one sitting* should be quite sufficient to enable an artist, who thoroughly knows his work, to turn out a good and highly artistic portrait. Without the aid of photography the *first sitting* would be almost entirely given up to the making of a complete *drawing* or sketch. This done, we proceed to give the first wash of flesh tint, and so the sitting ends. A good deal of the *work*, such as patching, &c., can then be proceeded with during the interval between the sitter's first and second visits. If any length of time were to elapse between the first and second sittings, the *background*, too, should be worked in. This is also advisable from the point that it is essential that the background should be painted in such a *tone* as not only to secure general harmony, but to be complementary to the leading tints in the face and hair. Where we have a photographic base to work upon we have only to give our first wash of flesh tint, guided by a detailed list of the colours, and, if I may so express it, the coloured peculiarities of the original sitter, and so prepare for further work. To produce really good work our *directions* or *detailed list of colours* should be exhaustive, otherwise there will surely be defects in our finished picture.

Now the *second sitting* for the picture we have drawn in should be utilised chiefly for putting in the shadows and half tones of the face, which endow it with roundness; then follow on with the colour in the cheeks, the hair. The figure will also receive its due amount of consideration. We will have to draw in and paint the leading folds and broad peculiarities of the drapery. This must be carried, as far as possible, to a finish, as we may never again have them under the same exact conditions. The masses of light and shade, too, should be indicated at this stage. If the dress be a very particular portion of the picture, which it very generally is in the case of ladies, I would suggest the assistance of a *lay figure*. As I say, if the dress be a matter of importance it should be placed upon a lay figure, and then the artist could have as many sittings from nature as he wanted, and the *drawing* would never be altered. In nature, every time the artist gets a sitting it would be almost a matter of impossibility to get all the folds of the dress and other leading points quite the same.

In a photograph all this is altered. There is a faithful drawing of the dress, with every fold and peculiarity shown and fixed. It is, indeed, such a faithful copy of the original that, if at all capable, we cannot go wrong. In this sitting, one of the most important points is the delicate indication and skilful adjustment of the masses of light and shade. Here, too, the photograph is a good friend, for it has, without trouble, secured those effects. It is true that sometimes they are exaggerated, but with taste and judgment we can very easily rectify what may be defective.

In the interval between the second and third sittings, we may, if so disposed, soften the tints of the flesh. Until one has had considerable practice and experience, and can be accounted proficient, little, if anything, should be added to the flesh in the absence of the sitter. I need not say that the thoroughness of this rule must be considerably dependent upon your knowledge of the sitter, be it from the life or through the help of your detailed list of colours.

As may be supposed, the *third sitting*, being the last, must be chiefly occupied in finishing and softening down the picture, and also in correcting any deficiency that may exist in the likeness generally. This done, we may presume we will have a very satisfactory portrait as a result.

Of course these *three sittings* are necessary only when the artist has to make his sketch from life; but when he has a photographic base *one sitting* only should, in the majority of cases, prove to be ample. You see, in the first place, the sitting utilised by the artist in making a sketch more or less elaborate is obviated by the aid of photography; and we are furnished with such a detailed sketch for colouring as no artist, however painstaking, ever puts in for his own use. Indeed, not only have we an exhaustive outline or sketch, but we have actually all the various degrees of light and shade. This, too, not only in the head and face, but the entire figures, or as much of it as appears in the portrait. All this is no small advantage, and I think it worse than nonsense trying to make little of the assistance that we can derive from photography.

One of the most important points in a portrait is the position. This refers almost equally to a head and bust or three-quarter figure. There are many instances where the artist *goes out* to paint a portrait goes with the sitter to the photographer's studio, and *poses* the subject. But even where this is not, or cannot, be done, there is little doubt that in a first-rate studio there will be an operative quite equal to the task of doing justice to a sitter in this regard. Of course, much of the value of the portrait is dependent on the *pose*. Much of the likeness and individuality of a sitter may be lost or secured by a very

slight turn of the head. It is, therefore, the first object of importance that the operator should examine carefully the sitter's face, and decide upon that position which would make the sitter's face appear the most agreeable as well as most characteristic.

We may, I think, accept the rule that wherever the features of a sitter are more than ordinarily *prominent*, a full face will be found to give the most agreeable results. This is the case simply, because in such heads the features are, in nine cases out of ten, less strongly defined. The position most frequently selected, however, is the three-quarter. This may at first sight appear remarkable, but on consideration it will be seen that the reason why this selection is so often made is that it combines to some degree the qualities and advantages of the full face and profile as well. There is a very considerable scope for the exercise of an operator's skill and judgment in fixing the exact proportion of a three-quarter head, considerable beauty and individuality being at stake. Another point, which is of vital importance, although to the unskilled it may appear unimportant, is the selection to be made between the different sides of the face to be turned to the operator; that is to say, whether the sitter will face, in three-quarter proportion, to the right or to the left. There is an enormous difference between the aspects of the two sides, and one will give a much more favourable portrait than the other. It will be remarked that there is a vast difference in the shadow and general appearance of the nose when photographed on the *right* side as compared with that of the *left* side. I have never met any one in my experience with both sides of the face alike, and I am inclined to say there is not a living soul whose two sides of the face are identical. As a natural result one must, therefore, present a better aspect than the other. A strange thing, too, is the fact that one side carries considerably more individuality than the other. I judge all these little matters by my own personal observation. As is only natural to one mixing so long with photographers and artists, I have been photographed a few times. Now a photograph of the right side of my face will give a very fine result. The nose is well defined and regular to a degree, and (*with considerable help from the retoucher*) might be considered, to a limited extent, attractive. This is all very nice and as it should be, I have no doubt, but it is not *my* likeness. The *left* side of my face carries all my individuality, and a portrait taken of it may not excite admiration as a picture, but there is the undoubted likeness of your humble servant. The idea that strikes you is not so much "What a nice picture!" as "What a good likeness!" As it is with me so is it with all others, only we will not recognise it if we do not enter heart and soul into our work. Profiles are not usually selected, for the reason that from a point of likeness its quality is naturally more limited than that of a three-quarter.

Having settled the position of the head satisfactorily as regards itself, the next point to consider is its position with regard to the body. There is a great lack of gracefulness when the head and body are turned in the same direction. To place a head to the best advantage, suppose the body turned to the *right*, the head should turn, in reason, of course, towards the *left*. Although there is more grace in this treatment, having the body and head turned the same way is not without its charm. A portrait treated thus is more remarkable for its simplicity than for its grace. I would suggest that the character of the man as expressed by his features should be the guide as to which should be selected. To the man who has artistic feeling in these points there are many considerations to claim his attention. An artist shows his skill in selecting that position which is best calculated, taking sex, age, and character into account, to secure an embodiment full of truthfulness and grace.

In a three-quarter length much beauty may be secured by the skilful placing of the hands; and I would suggest that, showing one, you show *both*. It is a very unpleasant feeling, and it may mar the success of a portrait, if the suggestion offers itself, "Where is the other hand?"

REDMOND BARRETT.

CAPTAIN ABNEY ON HELIOCHROMY.

CAPTAIN ABNEY, in a recent address before a section of the British Association, made some brief remarks upon the subject of heliochromy which are, in my opinion, so misleading as to call for correction. I quote as follows:—"The nearest approach to success in producing coloured pictures by light alone is the method of taking three negatives of the same subject through different coloured glasses, complementary to the three colour-sensations which together give to the eye the sensation of white light. The method is open to objection on account of the impure colour of the glasses used. If a device could be adopted whereby only those three parts of the spectrum could be severally used which form the colour-sensation, the method would be

more perfect than it is at present. Even then perfection could not be attained, owing to a defect which is inherent in photography. This defect is the imperfect representation of gradation in tone.

According to those recent text-books on colour which I have seen, only such light rays as are supposed to affect only one kind of nerve fibrils in the eye, or to excite only one of the fundamental colour-sensations, can be said to form or represent primary colour-sensations, and such rays are confined to both ends, and a narrow strip in the middle of the visible spectrum.* If Captain Abney means to assert that in a process of this character only those rays of the spectrum should act which represent primary colour-sensations, he is certainly mistaken, and grievously misleading all those who accept him as an authority upon this subject.

It is certain that every ray of the visible spectrum should act, and act nearly in proportion to its power, to excite the sensation of light in the eye. It would be ridiculous to expect that a process which reproduced the spectrum as three detached and widely separated patches of colour would correctly reproduce the infinite variety of compound colours in nature, some of which are made up chiefly, and most of them partly, of rays lying in other parts of the spectrum. There are some moderately bright colours which would reproduce like black by such a process.

But it is not easy for me to believe that Captain Abney means what I have inferred from his statement, although the expressions "parts of the spectrum" and "impure colour of the glasses" certainly support this inference. When he says "those parts of the spectrum . . . which form the colour-sensations," it is possible that he may mean the light rays in proportion as they affect the different kinds of nerve fibrils, or excite the different primary colour-sensations in the eye. If so, he does not mean to divide the spectrum into three distinct parts, but aimed to state a fact which was first observed by me, and plainly set forth in my book, *A New Principle in Heliochromy*, where I showed that each heliochromic negative must be made by the joint action, in due proportion, of all rays which affect the primary colour-sensation which it represents. It does not require screens of "pure colour" to do this—quite the contrary. Screens of "pure colour" are screens transparent to single regions of the spectrum only, and would not transmit all the rays that affect a single kind of nerve fibrils in the eye. The red, orange, yellow, and yellow-green rays all affect the nerve fibrils which produce the red colour-sensation, and all of them must therefore be transmitted more or less freely by the colour-screen used in making the negative representing that primary colour-sensation. But the orange-yellow and yellow must also be transmitted to some extent by the screen used in making the negative representing the green colour-sensation.

The screens must, in short, be so graduated in colour as to secure, in negatives of the spectrum, curves of intensity like the curves of a diagram representing the action of the spectrum upon the three kinds of nerve fibrils in the eye, or upon the three fundamental colour-sensations; and it is a fact that such screens had been produced and that correct heliochromic negatives had been made in considerable number, and with ease and certainty, before the beginning of this year.

The observation that the inability of photography to exactly represent gradations in tone would affect the accuracy of such a method of reproducing colours, of which Captain Abney now makes so much, originated with myself; but I also showed that by my method of proving the colour-screens by reference to the curves of intensity in the spectrum negatives, the effect of this defect in the negative process could be so far compensated for that it would no longer seriously affect the result, if suitable sensitive plates were employed. To say that this method does not solve the problem because of this defect, would be equivalent to saying that photography has not solved the problem of reproducing light and shade.

F. E. IVES.

—*Journal of the Franklin Institute.*

THE NEGATIVE IMAGE.

No. III.

AMONG the substances named as having affinity for the halogen of emulsified silver salt, the one nowadays most commonly found in the laboratory is probably normal sodium sulphite, Na_2SO_3 , and, therefore, easily available for the purposes of experiment. It may

* "Helmholtz, Maxwell, and Rood, as well as many other physicists, have developed the theory of Wunsch and Young, and have adopted the same, or very nearly the same, trial of primary colour-sensations. These fundamental hues or primaries . . . represent three widely separated and very bright colours of the spectrum."—*Colour*, by A. H. Church, M.A. London, 1887, p. 67. See also Rood's *Modern Chromatics*, pp. 120-23.

be regarded, and is in the following notes so taken, as a type of its congeners. Besides its well-known powers as a preservative of pyrogallol in solution, it has, it is believed, a slight solvent action on the haloid, and is also a feeble developer of the reduced image; it is probably to this complexity of characteristics that we are enabled to trace its value as a precursory aid to light.

Films of silver bromide on glass were treated with sodium sulphite in solution, the precise proportions being twenty grains to the ounce of water. The solution was allowed to remain upon the plates for the space of half an hour; they were then washed in several changes of clean water and allowed to dry spontaneously. When complete dessication had taken place some interesting changes in the properties of the sensitive substance were observed.

Held in moderately strong daylight the film rapidly acquired a dark purple colour; in a quarter of an hour it became hardly less black than a developed negative, viewed from either side, and, it is unnecessary to say, quite opaque. A plate coated with normal silver bromide was exposed at and for the same time. The relative difference in the colorific effects produced was the comparison of opposite extremes. Before it had thoroughly blackened, the debromised film (the term is employed under reserve) threw off a smell of bromine infinitely stronger than that coming from the non-treated film. A slight degradation of the characteristic hue of the pure haloid was induced by the action of the sodium sulphite. The half of a plate was immersed in the solution and carefully washed and dried. Viewed by the inactive red rays it was easily seen that the untreated half was perceptibly lighter; the same effect was apparent in white light.

The visible darkening of the debromised plate in unrestrained light took place much more rapidly than the reduction of silver chloride with excess of nitrate on paper. Portions of a debromised plate, carefully masked off, exhibited no change after having been kept in the dark for several days; therefore, it must be conceded that light is indispensable to the alteration, and that the reagent *per se* is ineffective.

A debromised plate was inserted in an ordinary printing frame behind a negative and exposed to daylight; a positive image of great beauty and softness was printed out. Again, such plates were exposed in the camera when visible negative images not inferior to some obtained by development of normal sub-haloid resulted. Without exhaustive experiment it is impossible to allege a specific sensitiveness to such plates, but it may be said that under the most favourable conditions of light and lens, the original rapidity of the plates being of the medium or instantaneous kind, not more than a minute should suffice for the positive in the frame, and two for the negative in the camera; but these data are in no sense absolute, and are given solely with the view of providing essential details.

The phenomenon of the reversed image results from over-exposure, while in some comparative trials it was found that given two plates of normal bromide differing in sensitiveness the relative rapidities were maintained in the debromised state.

The solvent action of sodium hyposulphite upon these directly produced images is far greater than upon pictures that result from brief exposure and development of normal bromide; it dissolves the unaltered portions very readily, and attacks and weakens the positive or negative deposition to a perceptible degree. By prolonging the immersion for twenty-four hours the image is all but obliterated. Negatives of such a description are not adapted for printing purposes without intensification, and apparently the purplish-brown deposit that forms the image will not enter into combination with the mercuric salt.

Following upon the fact just stated, an obvious question presents itself: Are these direct impressions formed of metallic silver? Has light, foreaided by the halogen "absorbent," accomplished that which this present writer claims it will do in the future, namely, produced a direct visible negative image in metal? The evidence either way is inconclusive: sodium hyposulphite unquestionably has great solvent action upon the deposits; hydrochloric 1:10 dissolves them easily. It can be argued that upon deposited metallic silver neither the one nor the other has such a power in anything like the same degree. Moreover, a debromised plate that has been allowed to blacken spontaneously is, if we except the instability of the vehicular body, unaffected by moderately strong nitric acid, and the images obtained in the camera and the printing frame are, after fixation, insoluble in the same reagent. Such facts point clearly in one direction; nevertheless, it is open to us to assume that with allotropic forms of silver the nitric acid test is not admissible.

The debromised plates appear to lose direct sensitiveness by being kept for periods of days before exposure; if exposed wet they seem to be more sensitive than when dry. Their sensitiveness to the

developable action of light is much less than that of normal bromide plates, but, on the other hand, the impression obtained by correct exposure takes upon development remarkable density. The faint negative effect produced by under-exposing a debromised plate for a visible picture can be developed to the requisite intensity in the ordinary manner. Such deposits, in contradistinction to the visible images obtained by exposure, are readily soluble in nitric acid. The density possessed by developed impressions on debromised plates suggests that where difficulty is experienced with a particular emulsion in getting negatives sufficiently dense, a remedy, at some sacrifice of rapidity, is at hand by the employment of a preliminary treatment with an absorbent of halogen.

As establishing some similarity between the body obtained by the prolonged exposure of a debromised plate, and the substance left on such plates by development without exposure, it was found that by the latter procedure a dark homogeneous deposit, seemingly of a metallic nature, was obtained, and that it exhibited precisely the same reactions with sodium hyposulphite, nitric and hydrochloric acids, as the printed-out images.

The following equation probably represents the chemical change undergone by the sensitive film upon the application of sodium sulphite before exposure:—

The symbol for the altered haloid implies a belief in the formation of some such body as sub-haloid or sub-salt. Upon applying sulphuric acid and heat to portions of the sodium sulphite solution in which plates had been soaked, the escape of brown fumes indicating the presence of hydrobromic acid appeared to confirm the correctness of the stated reaction. But a question whether the equation was literally reliable, and also whether the actual presence of sodium sulphite in contact with the film was not necessary to the blackening action of light, led to plates, after removal from the sulphite, being (1) thoroughly washed in water and, finally, in methylated alcohol; and (2) allowed to dry without being washed. Upon exposure side by side, the washed plate exhibited by far the greater depth of blackening.

Relative to the visible action of light on modified silver bromide, others of the halogen absorbents were experimented with, but did not exhibit distinctive features that call for reference on this occasion.

THOMAS BEDDING.

THE GROTTO OF HANS.

PHOTOGRAPHERS desiring an enjoyable holiday, and at the same time searching for new fields to conquer, will find the district in and around the Forest of Arden, in Belgium, well worth attention, and as their implements of war are no more harmful than "glass, brass, and wood," with some flash or magnesium lights as a reserve, they can dispense with the impedimenta that generally accompanies an invading army.

Among the wonders of nature, some of the most fascinating are the subterranean caverns and water-courses that are to be found in various parts of the globe, but few, if any, known, are so extensive, curious, and majestic as the series of stalactitic caverns known as the "Grotto of Hans." It seems very little known to travellers, especially English, and the guide-books only mention it in a cursory manner. I was lead to include it in my round of sights by the remarks in the small guide of the London Chatham and Dover Company, in which they "strongly recommend tourists not to miss seeing the caverns." In emphasising this, I can candidly say, that if I had travelled several hundred miles out of my route, instead of fifty or so, what I saw would have fully repaid me for the extra time spent in doing so.

The cost of travelling in Belgium, as is well known, is inexpensive, and when one gets away from the low-lying country around Antwerp and Brussels, the scenery is very picturesque, not that these two cities are not well worth visiting for the capture of "light writings," for are they not the homes of some of the most celebrated artists? but in a different way do they have to receive attention from the bearer of a camera. They represent the "art" side, with the beautiful architecture, painting, and sculpture, whereas the district I wish to write about is full of "Nature." Wishing to get the greatest change possible in a holiday of ten days, I was attracted by an excellent little book entitled *Walks in the Ardennes*, and finding the scenery described and depicted in it to my mind, I looked in the Great Eastern Railway Continental timetable for a circular ticket that should touch this district, and found one that for a sum under two pounds included a second-class ticket to Spa, with power to break the journey at Harwich, Antwerp, Louvain, Malines, Liège, Pepinster, with special facilities (being exhibition year) to visit Brussels, either going or returning.

Accompanied by a friend, I left by the eight p.m. train from Liverpool Street Station on Saturday, and in two hours reached Harwich, the train drawing up by the side of Parkstone Quay, which, together with the station, was well lighted by electricity, the excellent steamers of the Great Eastern Railway Company are then readily boarded. One cannot

but be pleased with the boats, for they are large and comfortable, and several on the service are fitted with incandescent electric-light lamps, which not only give a far better light, but in the case of an enforced sojourn in the cabins the absence of the smell of oil is a great boon. On this particular night the sea was very calm, and so no trouble was given the steward, except to satisfy the sharp-set appetites of the passengers. Should the crossing take place in rough weather, it is wise to pay the extra for a first-class sleeping berth.

Without going into the minutiae of the journey in its various parts, I will at once say that the photographer will find his time well occupied in Antwerp for two or three days getting "pictures;" and from the fact that a trio of well-known enthusiasts in the photographic world returned from Antwerp in the same steamer that I did with perfect satisfaction depicted on their faces and in their manner, I am sure no one who follows their example will be sorry for spending the evening and night in train and boat to get from London (or the Midlands) to Antwerp, and vice-versa, for most passengers manage to sleep well for several hours on board. In the busy season you have to hurry up from the train to get a choice, but the first-class berths can be secured or reserved by telegraph. From Antwerp we went to Liège, and there spent the afternoon and evening. This, the Birmingham of Belgium, as far as its trade is concerned, is a very finely situated place, and has some fine scenery surrounding it, a capital river, and a very ancient and picturesque palace, now used as municipal offices; besides which there are broad and open places, and fine streets, and high-class shops.

It was from Liège we started for the Grotto of Hans, and it was reached by first taking tickets to a place called Jemelle, the train for which leaves about seven o'clock in the morning, and the journey of about forty kilometres (say twenty-three miles) was performed in two hours. This, no doubt, in England would be voted decidedly slow, but as the scenery is very beautiful on the way, one can enjoy it all the more by reason of the slow travelling; while at one or two of the stations the time would be sufficient to get some pretty pictures, and with a clip capable of attaching to the door or window of the railway carriage this could be easily done. One place was particularly charming, it is called "Comblain-au-pont," which takes its name from a bridge. The costumes again, here and there, are worth perpetuating. During the journey from Liège to Jemelle the railway rises 500 feet, and Liège being 250 feet higher than Antwerp, it will be understood that the undulating scenery, either with the charming morning tints on it, or the lovely flood of moonlight, as was presented to our gaze on returning through vale and over hill, is beautiful in the extreme.

On arriving at Jemelle waggonettes are waiting to take the travellers to the Biron Hôtel, Rochefort, where an English-speaking waiter soon attends to your comfort, and with a quiet word in his ears he will have the front seat of the waggonette kept for you, if not already bespoke; and, strange to say, it was not on this day, for here, as in other parts of Belgium, the seats beside the driver are not sought after; in fact, in the trams, &c., are considered and priced second class. How different to our English notions and the value set on box seats of coaches, &c.! The ride of eight kilometres takes about three-quarters of an hour, and is along a splendidly made road (and Belgium is noted for its well-made and kept roads), with woodland and magnificent firs on one side, and the open country with its background of hills on the other. A more charming ride on a day such as we had in September last year, with its cloudless, blue sky, could hardly be imagined if not found in reality. Presently the waggonette stopped and the passengers alighted to be joined by parties that had come from other parts, namely, Namur, Dinant, Givet (frontier town), &c.; as these towns in the Ardennes can be reached from Brussels or France, the tourist has an alternative method of taking in "the Grotto" on his journey through Belgium. In all assembled at the entrance of the Grotto was a party of fifty, and prior to leaving the splendid sunshine, an inspection and "shot" at the water course of the River Lesse must be taken, for it is a sight as it comes rushing out of the rock in which the Grotto, or rather the caverns are formed.

Should the tourist desire to get a few photographs of the "dark places of the earth," he will now prepare his detective camera, and having the flash light ready at hand in a safe satchel, with some of his friends carrying a couple of magnesium lamps, rejoin the rest of the party and gain a few particulars before entering.

Some idea of their size may be gathered from the fact that this rock, which is covered with a wood, is 5000 metres in circumference, or about three miles, and it took us three hours to explore the caverns, being on the move all the time, with the exception of a short rest about half way. The lights are provided by the proprietor, and consist of paraffin lamps of the Silber model, with two burners on one rod, and are carried by children (girls and boys) and a few women. These range themselves among the party so as to fairly illuminate the footpaths and not get too many shadows; and when all are marshalled the guide leads the way, and in a clear voice gives his descriptions and explanations in French. He is not remarkable in dress, except that he wears a curious girdle, and this, we find later, is of great practical value, for it is the hempen threads that form the wick for certain of his torches and illuminations. He is strong in limb, and, as he proves, surefooted; in fact, one can give him the credit of being a champion guide and entertainer as well.

No sooner do we enter and begin to look about than we see something to admire—beautiful stalactites, taking all sorts of fantastic shapes; and

as we pass from corridor to hall, and gallery to *salon*, fresh wonders meet our eyes at every step. It would take a volume to describe in detail all the natural beauties of the Grotto; but as my thoughts wander back, I think of the lovely alabaster-looking groups of cathedrals, fortresses, colosseums, dome buildings, thrones, animals, draperies, and birds, all formed by the dropping of water containing the potash or other calcareous matter that is imparted to it in passing through the earth and fissure of the rock above. I found by means of a sensitive watch-size pocket surveying barometer I had with me that the general level of the Grotto was about 650 feet above sea level, that is, about 400 feet above Liège, our starting point in the morning, and we are told that it is ninety-two metres, or about 280 feet above the bed of the river. No doubt in times prehistoric some great geological change caused these caverns to be formed, and they have been altered by the torrent of water that no doubt at one time passed through the different parts of the cave, but are now diverted into other channels; and from the fact that Roman medals, large quantities of money, human bones of large size, having been found, and other signs, there is little doubt that the caves have been inhabited.

G. R. BAKER.

(To be concluded.)

ELECTRIC LIGHT IN THE LANTERN.

I HAVE just seen the letter of Mr. Baker on this subject. If any of your readers have facility for getting current, they need have no trouble or delay, and very little expense, in availing themselves of such a light, as

Fig. 1.—LAMP.

Fig. 2.—HOLDER.

power, and as it works at from 80 to 100 volts, requires 5 to 6 ampères.

These lamps are sold at 10s. each, and a little fixing is sold at option for 3s. 6d., which is simply screwed on a block of wood, or screwed or soldered to the metal bottom of the lantern. Nothing at all peculiar need be done to any lantern beyond adjusting this block approximately to the right height; the fitting itself gives ample final adjustment within reasonable limits. The purchaser who is fortunate enough to command it, has nothing whatever to do further, beyond getting in his current and arranging a switch for it.

November 4, 1889.

LEWIS WRIGHT.

[The figures appended show exactly what the lamp is, and how it is fixed in the lantern.—Ed.]

NOTES FROM NEWCASTLE.

I NOTICED some discussion still going on about the "Amateur" question. I don't think the local photographic world is troubled much in this particular, but we occasionally meet with "Amateurs" whose con-

sciences are of an easy texture; for instance, I knew of one who had some hundreds of cabinet mounts stamped with his name and address by a printer friend of mine something after this style—

JONAS SWINGBACK,
AMATEUR PHOTOGRAPHER,
RISING TERRACE,
NEWCASTLE-ON-TYNE.

"Copies may be had."

I thought this pretty good for an amateur, but now I hear of a large order for lantern slides (of local scenery) and photographs placed in the hands of another "person of the amateur persuasion," price, &c., all fixed.

Mr. John Pike, chemist and photographer, has been elected the first President of the new Chemists, Assistants, and Apprentices' Association of Newcastle, and delivered an address to the members on the occasion of the inaugural meeting the other day.

The accession of some eighteen or so new names to the membership roll of the Newcastle Photographic Association ought to be a matter of grave consideration by the Executive of that body, from the fact that these new members evidently expect to receive *something* in return for their expenditure of time and money in place of the "dry bones" which have had to do duty at the monthly meetings for some time past. After all, the members have it in their own hands to make or mar the Society; and if these eighteen mean business, they can do a great deal to improve and revivify the Association. The Executive should either do something for the members, or the members should do something on their own account. I am afraid the "wet blanket" business is too often applied by the elder to the younger and more enthusiastic of the members.

The death of Mr. Goold (photographer to Messrs. Armstrong, Mitchell, & Co., of the Elswick Works) caused some two years ago a vacancy which an experienced photographer might well have hesitated to fill. It is no easy matter to get good and perfect (as regards detail) negatives of machinery, and hardly less difficult, in a district which boasts more than one photographer of very considerable skill in work of this kind, to submit proofs which will satisfy the demands of firms of this standing, the appointment was, however, conferred upon Mr. J. E. Goold, son of the above-mentioned, at the time a draughtsman with the firm, and who had had little or no experience of photography; luckily, Mr. Goold the younger had some art training and chemical knowledge to fall back upon, aided by first-class studio arrangements and apparatus of the highest order, and very quickly mastered the *technique* necessary for success—how well these difficulties have been overcome is evidenced by the beautiful instantaneous photographs he has just taken for the Elswick firm of H.M.S. *Victoria's* gun trials at sea. Mr. Goold was despatched recently to Chatham for this purpose, and has returned with photographs which have delighted the firm, and every one who has been privileged to see them—as, for instance, the members present at the last meeting of the local Society, and others. It is to be hoped that one at least of these will soon be reproduced and published in one or more of the illustrated papers—Mr. Goold's work has been seen on the walls of more than one exhibition, and received a medal award at Cardiff recently. Mr. Goold has often large orders for photographs necessitating special appliances; and a description of the studio and suite of rooms will, I have no doubt, at a future time, interest your readers.

I dare say some of us will remember a time when such signs as "Easy shaving and photographs taken," "Hairdresser and photographer," were pretty common; nowadays, "Physic, photographs, and fiddlestrings" are not so often met with in such close proximity. I know one photographer, however, not many miles from here, whose hobby is "phrenology," and who is only too happy when a chance presents itself of trying his skill; this led the other day to something like the following dialogue between himself and a local "pit laddie":—

"Noo, then; is thoo bizzzy?"

"Not very; I shall be free in a minute or two," said the disciple of the camera.

"When thoo's dune, a'll want thoo ta strike me, an if it's a good un, a'll hev thoo ta tak wor Bill; aw wad like him teyken stealin' sugar oot o' the bason, an t'other bit laddie gawn ta slap him."

Replies the photographer: "Do you think he would stop in a mischief long enough?"

"Mischief lang enough, man; wey, he's nivver oot."

"He is evidently a sharp, clever boy; you should have his head examined."

"His head egsamined, man; wey, ma wife egsamines his head ivvory weck end ta see if there's enny big uns in't."

D. D.

Foreign Notes and News.

HERR E. COHEN, of Amsterdam, has recently succeeded in obtaining some interesting photographs of falling streams of water. He employed a vessel from the bottom of which issued a column of water one centimetre thick. The apparatus was placed in a dark chamber and illuminated by the spark of Ruhmkorff's coil in connexion with a Leyden jar. The falling column of water had a velocity of 8.28 m. per second, while the period of illumination was reckoned by Cohen at about one 82,800 of a second. The results turned out most successful—the elevations and depressions of the stream as well as the separate drops being clearly distinguishable. The definition obtained in this way was of course far superior to anything that could be reached with magnesium flash-light apparatus, as the period of illumination would be far too long to give distinctness to the impressions of the different drops. It will be remembered that Professor Mach employed the same means of illumination for obtaining his celebrated photographs of bullets during their flight, and it appears to be about the best means of obtaining sharp impressions of moving objects, provided of course that they can be got into a dark chamber.

THE *Revue Suisse de Photographie* gives an account of some experiments conducted by F. A. Forel, for the purpose of ascertaining the photographic transparency of the water of the Lake of Geneva at different times of the year. The gentleman in question, who has placed the results of his work before the Academy, employed in his researches ordinary albumen paper. He fastened upon a line 130 m. long, a number of small water-tight copying frames, each 10 m. from one another, in which the sensitised paper was contained. The whole concern was sunk in the lake at night, after the manner of the wily fisher for eels when setting a night line, but with almost more precaution. It was permitted to remain there until a sunny day had illumined the bosom of the lake, and then with similar caution and secrecy drawn up during the following night. The result proved that the water attains its maximum of transparency during winter, the action of light being then still apparent at a depth of 350 feet. In July, on the other hand, complete darkness reigned at a depth of 150 feet. M. Forel attributes the comparative opacity of the water in summer to its containing a greater amount of organic impurities.

THEORETICAL, speculative Germany is bidding fair, it would seem, to outstrip "practical England" in her own especial domain of practicality. The good town of Hamburg has recently added to other institutions a police photographic studio. Two negatives are taken in different attitudes of each criminal who gets within the clutches of the law, and being preserved in the archives of the city render future identification easier for the police, and the denial of previous convictions harder for the accused. The studio is located in part of the criminal court, and the method adopted is to introduce the individual into it, seat him upon a stool, the plate being already within the camera, which is focussed for the stool in question, and the physiognomy of the criminal is already imprinted upon the gelatine before he has had time to impart to it that air of preternatural innocence which renders the photographs of hardened law-breakers often of so little use as a means of identification, when they have had time to prepare themselves for the ordeal.

PROFESSOR EDEN sums up his experience of eikonogen in the following note in the *Photographische Correspondenz*, which explains amongst other things how eikonogen appears in this country under the varying forms complained of by one of the contributors to the *JOURNAL*. "Eikonogen" he says "was discovered by Dr. Andresen, of Berlin, and has been manufactured since the spring by Krügener, of Frankfurt: first in the form of a greyish powder, but now in the form of compact granular crystals. It is in reality the sodium salt of Amido-B-naphthol-B-mono-sulphuric acid, its formula being $C_{10}H_{13}\left\{\begin{array}{l} SO_3Na \\ OH \\ NH_2 \end{array}\right.$ It forms a white crystalline

powder, the aqueous solution of which does not get brown in the presence of sodium sulphite when exposed to the air. Its action on bromide of silver gelatine plates is to produce very beautiful gradations with delicate half tones. It never clouds emulsion plates, and acts very beneficially in relation to their degree of sensitiveness. It has been for some time employed in the Vienna experimental school of photography."

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 31.—Mr. H. Haddon in the chair.

Mr. C. H. COOKE showed some negatives on Carbutt's celluloid films. They had been given him by a friend who wished to know the cause of a number of semi-opaque spots appearing on them.

The opinion of the members was that the spots were caused by pressure of the films against each other, probably in conjunction with some friction.

A question from the box was read:—"What is the best colour for the walls of a dark room?"

Mr. A. L. HENDERSON said that he would line a large dark room with white and a small one with black.

Mr. W. E. DEBENHAM and Mr. A. MACKIE considered yellow to be better than white, as it reflected nearly as much visual light when lighted by the dark-room window, but did not reflect powerfully acting rays, some of which might enter by the window.

The CHAIRMAN suggested that Mr. Henderson might have something of interest to tell the members on his return from Australia.

Mr. HENDERSON said that he had brought back a very fine collection, principally of New Zealand photographs, which he would bring to a future meeting. He had also a print by a New Zealand photographer—Morris, of Dunedin—in which there appeared something of the natural colour in the face of the sitter. That he would also bring.

Mr. J. HUBERT then read a paper commenting principally upon the report of the proceedings of the previous meeting that had appeared in a contemporary. He also said that after the meeting he tested the water in the zinc can from which he had taken his supply, and found it to be strongly acid—apparently with acetic acid; this would account for the slow and imperfect appearance of the image when he attempted to develop it.

The discussion of the previous week's paper being open, Mr. DEBENHAM noted that it was advised to lower the light or use a coat of coloured varnish over the negative if there was insufficient intensity. Did Mr. Hubert affirm that with a proportionately short exposure to a strong light the result was less vigorous than with a sufficiently long exposure to a weak light?

Mr. HUBERT replied that it was at all events easier to give correct exposure with a weak light than with a very strong one.

Mr. F. A. BRIDGE maintained that there was an essential difference in the results from a weak and from a strong light; some negatives were so dense that a weak light would not get through them, no matter how long might be given. He had negatives that he could not enlarge by limelight.

Mr. HENDERSON said that in making transparencies in the camera he got more density by stopping down the lens.

The CHAIRMAN inquired whether Mr. Hubert had tried other developers than ferrous oxalate.

Mr. HUBERT replied that at the previous meeting he had submitted several pictures developed with hydroquinone and with pyro. He had tried eikonogen that day both for bromide enlargement and for negatives. For the latter purpose he did not like it, as it took so long to develop with it.

Mr. HENDERSON inquired whether any good developer could be recommended for plates that had been exposed for several days to an atmosphere containing seventy-five per cent. of moisture and at a temperature of 90°. He had tried carbonate of lithium instead of ammonia. With the usual method he had obtained a reversed image.

Mr. L. E. Morgan was elected a member.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

At the Committee meeting held on the 11th ultimo Mr. W. M. Ashman was elected on the Committee.

On the 25th ultimo and the 1st instant the Committee were engaged in considering the revision of the rules of the Association, with a view to enlarging the scope of its action and the rights and conditions of membership. At the latter meeting the Committee dealt with an application for assistance, and made a grant to meet the case.

PHOTOGRAPHIC CLUB.

ANNUAL MEETING, Auderton's Hotel, Wednesday, November 6, 1889.

The following officers were elected for the ensuing year:—*Trustees*: Messrs. W. Ackland and T. Charters White.—*Committee*: Messrs. W. F. Benham, W. P. Cembrano, H. E. Davis, E. W. Foxlee, F. Haes, A. Mackie, J. B. B. Wellington, and J. W. Zaehnsdorf.—*Librarian*: Mr. C. D. Hesse.—*Curator*: Mr. H. M. Hastings.—*Recorder*: Mr. E. Clifton.—*Hon. Secretary and Treasurer*: Mr. F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

NOVEMBER 5.—Mr. J. TRAILL TAYLOR (President) in the chair.

This being the annual meeting, certain proposed alterations in the rules were adopted.

The Council's report, together with that of the Treasurer, showed great activity and financial prosperity as the result of the doings of the past year.

The election of officers and Council then took place, the following being elected:—*President*: Mr. J. Traill Taylor.—*Council*: Rev. E. Healy, Messrs. W. Bishop, G. J. Clarke, J. Douglas, A. Mackie, L. Medland, J. Oakley, F. G. Reader, H. Walker, W. Few.—*Curator*: Mr. W. T. Coventon.—*Secretary and Treasurer*: Mr. N. Percy Fox, 2, Princess-terrace, Primrose-hill, N.W.

A new member was admitted.

Next meeting will be a lantern night.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

OCTOBER 28.—Mr. J. HUMPHRIES in the chair.

Mr. S. HERBERT FRY gave a lecture and demonstration upon *Bromide Paper and Enlarging*. In the course of an hour's address he touched upon the salient points of the process, remarking that his object was to give the benefit of his personal experience, and not to give the members an elaborate essay. A portrait negative enlargement was then made and developed, and the method of vignetting and exposing in the draperies illustrated. Afterwards Mr. Chang passed up a landscape negative which Mr. Fry enlarged to 15×12, and then demonstrated his method of printing in a sky from a separate negative.

The lecture and demonstration were full of practical interest.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

FRIDAY, November 1.—Mr. F. W. EDWARDS (President) in the chair.

Mr. Aland elected as member.

The business of the evening consisted of a demonstration of *Development* by the President and Mr. Dowling.

Some positives on ground glass, by Mr. Dowling, handed round for inspection, were much admired.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held at the Masonic Hall on November 5.—Mr. B. J. Taylor (President) in the chair.

Mr. J. Hawkley was elected a member.

A demonstration of lantern slide making was given by Messrs. T. J. Hibbert, Furness, and Brown, the two former using the Alpha plates and developer as sent out by the makers, and the latter using Thomas's plates and Mawson's developer. Mr. Hibbert also exhibited the acme camera by Watson & Sons.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 1.—Colonel Playfair in the chair.

A suggestion was made that negatives which have done their work and are no longer in use by members should be brought to the monthly meetings and exchanged for mutual benefit. This received the favourable consideration of those present.

Dr. HARMAN BROWN read a paper on *The Eye considered as a Camera*.

The next meeting will be held on Friday, December 6, when Mr. H. A. H. Daniel will read a paper.

DARLINGTON PHOTOGRAPHIC SOCIETY.

NOVEMBER 4.—Annual meeting.—Mr. G. NEWBY WATSON presided.

The annual report was of a very satisfactory character. The number of members showed an increase of ten during the year.

The following gentlemen were elected to the Council for the ensuing year:—*President*: Mr. E. Ensor.—*Vice-President*: Mr. G. Newby Watson.—*Council*: J. A. Fothergill, H. W. Holmes, R. A. Luck, W. F. K. Stock.—*Treasurer*: Mr. T. Howlett.—*Hon. Secretary*: Mr. W. Ganitte Brewis.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

OCTOBER 31.—Mr. A. W. Beer in the chair.

The following gentlemen were elected members:—Messrs. T. C. Morris, J. O. De Wolf, and J. H. Swift.

Announcement was made that Mr. H. P. Robinson, of Tunbridge Wells, had kindly promised the loan of his valuable collection of pictures on the close of the exhibition in the Camera Club. The pictures will be on view in the rooms for a month or six weeks.

Mr. J. S. BROWN read a paper, *From Cairo to the Cataract*, illustrated by a number of excellent lantern slides; after which a selection of slides were

projected on the screen. These had been developed by hydroquinone on the new Hord plates, showing the peculiar warm colour obtained by different exposures to gaslight, explanations being given by Messrs. W. Tomkinson and F. A. Schierwater.

Attention was drawn to a communication from the Hon. Secretaries to the Association of the Literary, Scientific, and Art Societies of Liverpool, that a *soirée* will be held in St. George's Hall on Wednesday, December 18, requesting the co-operation of the members of this Society.

A smoking social concert will be held at No. 3, Lord-street on Friday, November 15, at a quarter to eight, the musical arrangements for which will be under the direction of Mr. H. H. Williams. There will also be a lantern evening on Thursday, November 21, at seven o'clock; subject, *Normandy and Brittany*, by Messrs. J. A. Sinclair, W. Tomkinson, and E. M. Tunstall. One hundred and fifty slides will be shown.

BATH PHOTOGRAPHIC SOCIETY.

OCTOBER 30.—Mr. W. PUMPHREY (President) in the chair.

After the disposal of preliminary business, a discussion was opened by the *PRESIDENT* on *Stops and their Value in Photography*. In the first place, he pointed out that advantages were gained at times by admitting a large amount of light through a given lens, especially if the subjects were near at hand, as in portraiture, or for instantaneous work. The flatness of field in such cases would be greatly restricted, as the elementary principle of a stop was to reduce the effect of marginal rays and so increase flatness of field; this was clearly illustrated by means of diagrams showing the course of parallel and oblique rays with and without a diaphragm. The following points were dealt with:—The primary use of stops to flatten the field; and, secondary, to give proportionate exposure. To do this it was necessary that the diameter of stop used should have a definite relation to the focal length of the lens; that the plate shall have a definite sensitiveness; that there be a definite standard of light; and that a ready measure of small lapses of time be provided. The standard adopted by the Photographic Society of Great Britain of numbering stops was referred to, *f*-64, &c., meaning that the diameter of *f*-64 stop is equal to one-sixty-fourth of the focal length of lens, and, other conditions being equal, this was constant. Regarding rapidity of plate the speaker deprecated the practice of shifting from one make of plate to another without good reason, as it led to uncertainty. As a measure of time, mechanical means must be resorted to, for no one could expose by hand so short a period as one-twentieth of a second, much less one-sixtieth. A time shutter—working at one-sixty-fourth of a second and adjustable to slower movement, three seconds—was shown in action. Some remarks upon the iris form of diaphragm were also made.

In the discussion which followed the President's address, Mr. BRAHAM contrasted the human eye and the eyes of animals with a lens—the iris being the natural stop or diaphragm, adjustable more or less according to the power exercised by the muscles. He also sketched the passage of rays, forming an image in a pinhole camera to illustrate the smallest diaphragm.

Mr. AUSTIN J. KINO gathered from the Chairman that for landscape work a small diaphragm was to be preferred, but wished to know why it was not the practice to use the smallest stop the subject and light would admit of?

The Chairman generally worked at *f*-32, which gave him a sharp picture, and when the nearest object was not less than thirty yards away there was no occasion to alter the focus of the camera.

Mr. W. M. ASHMAN (Secretary), in answer to Mr. King, said that in portrait work small stops diminished the brilliancy and rotundity of the image; here flatness of field was not essential or desirable. In the case of certain outdoor subjects a moderately large stop was thought by many to yield a more natural representation than when a small stop was used—one gave an idea of atmosphere, the other was map-like.

Mr. Perren used the largest stop he could compatible with good definition.

Mr. RUDGE inquired whether the stop did not in the case of oblique rays merely check the passage and cause them to be forced with the more parallel rays through the aperture.

The CHAIRMAN replied that if such were the case colours would be produced.

Mr. BRISCOE said a new stop had been suggested by a Mr. Zimmer to work diagonally in the lens tube, the object being to increase the exposure of foreground and diminish that of the sky.

This led to a discussion on the shape of stops.

Mr. HARbutt spoke of a disc of perforated zinc being used with satisfactory effect in front of a lens.

Another member had seen such stops with a central opening of the usual size employed between lenses of portrait combination.

The question of circular *versus* rectangular diaphragms was also considered, the Chairman, Messrs. Braham, Harbutt, and the Secretary, giving their own views as to whether openings of equal area were similar in effect upon the plate or the reverse.

The next ordinary meeting will be held on November 27.

ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY IN BERLIN.

In the meeting of October 18, Mr. E. Vogel delivered a lecture recording his experience in regard to dark chamber glasses. He showed by a series of experiments with red glass, with the assistance of a spectroscope, that light rays exactly similar when considered optically may act in a very different manner actinically, as part of the red glass keeps back the effective rays while the remaining portion does not, and lightness of hue gives no indication whereby this might be determined. The lecturer produced very good perfectly black enlarged views on bromide of silver paper, developed by means of eikonogen. This agent, he said, by the way, is no longer put on the market as a grey powder, but in the form of fine colourless crystals. The lecturer would rather recommend it for positive than negative development.

Dr. ZENKER described a method of taking photographs through a small opening without an objective; also through two intersecting slits, whereby

considerably distorted or caricatured images might be obtained; the process being otherwise of no practical value.

The meeting finally adopted the resolution, "That the library of the Association be enriched by the addition of a number of new Journals and Year-books."

CLUB DER AMATEUR PHOTOGRAPHIEN.

Is the general meeting, October 12, a panoramic view from Paris, taken by means of Moxsari's apparatus, was the principal object of interest.

Herr GOLDMANN, jun., gave a description of the instrument employed, confining himself, however, to its principles only.

Two platinum *genre* prints from Georg Brockesch, of Leipzig, excited admiration both by the beauty of the composition and the effective treatment of the positive prints. The platinum prints of Mr. W. Winter, of Derby, exhibited by Herr C. Ulrich, did not surpass the well-known picture, *My Mummy*, by the same author. The photographs taken during a journey through India and China, by Baron Joachim von Brenner Felsach, were really excellent productions for an amateur; the same might be said of the views produced by Mr. Putz. But the *pièce de résistance* of the evening unquestionably was the lecture delivered by the Imperial Councillor Luckhardt on the retouching of negatives. None of the subsequent items of the programme could attract the general attention in the same degree, though the leggel-stand of Dr. Ed. Suchanek for detective cameras was remarkable for an instrument which is compressible into the smallest possible space.

Correspondence.

Our Correspondents should never write on both sides of the paper.

MR. H. P. ROBINSON'S PHOTOGRAPHS AT THE CAMERA CLUB.

To the Editor.

SIR,—There has of late been a good deal of controversy about the comparative merits of sharply focussed and out-of-focus photographs, which would not have been less creditable to some of the disputants, nor less useful to the readers, had there been less personal feeling manifested in the discussion.

By reading the very clever letters on both sides of the question, I have got some instruction and a little amusement, but the strongest impression they have left with me is regret that a better and more amiable tone has not characterised them. If the discussion was started in the interests of photography and photographers, as it ought to have been, that laudable end seems to me to have given place, in great measure, to ill-feeling and a desire to write a clever letter. I am neither able nor willing to make the expression of an opinion an excuse for smart writing, nor do I intend to discuss the vexed question of realism or any other ism. By the courtesy of the Committee of the Camera Club, I have had the privilege of seeing the outcome of Mr. H. P. Robinson's years of what I am disposed to think earnest and, without doubt, clever work now exhibited at the Camera Club, and it is about this exhibition that I ask your permission to say a few words.

Let me confess at once that I am but an indifferent worker with the camera, and that, rightly or wrongly, I have as great an admiration for Mr. Robinson's photographs as he has himself—perhaps a greater considered as photographs; but we should probably each put a widely different value upon them, considered as pictures. I grant that the science of them is great, but I think the art of them is small. If a picture does not suggest nature, it is, as a picture, bad; and if it claim to be an example, misleading.

Mr. Robinson's work is so notoriously important in size that it must command attention, therefore, it is of no little moment to young amateur photographers to ascertain whether it is or is not worthy their study, as the works of the "Old Masters" are worthy the study of art students. That is the question I ask, and I should like to see it dispassionately discussed. Does the Committee of the Camera Club exhibit Mr. Robinson's photographs for educational purposes, or from feelings of courtesy and personal regard for him?

Mr. Robinson has earned, and justly, both money and fame by his photography, and he could scarcely be expected to call the bridge rotten that has carried him safely over. His photographs have served their purpose and his, but the *raison d'être* of their existence is a thing of the past. They are photographs, and not pictures, and that is what photographs now aspire to be, what they ought to be, and what they must be, or photography will never be worthy to be called an art-science, nor a photograph a work of art. What would be the effect upon an artistic mind and temperament if its owner had to live in a house the walls of

which were adorned as the Camera Club's rooms now are? Silver prints as large as those exhibited by Mr. Robinson must always be unpleasant, even if the prints have not other and greater objections.

The combinations are more deftly done than, perhaps, any other person could do them, but they are not naturally done; that is to say, not in a way to suggest nature; they are unnatural (if not impossible) and, therefore, unpleasant and worse. The figures are too evidently models, dressed as peasants, fisher-girls, &c.; but they are not, and do not look like, peasants and fisher-girls. They are posed by the photographer, and not posed as the occupations represented would have posed them. In some cases they are out of scale with the surroundings. In others, shadows seem to be thrown from more than one source of light. The sun-bonnetted model is repeated *ad nauseam*. Having read some of Mr. Robinson's writings, I am almost sorry I have seen his photographs.

Mr. Robinson would be, perhaps, the photographer before all others I should like to consult in any manipulative difficulty, be the process what it might; but I should avoid, rather than be led by, his silver-printed combination photographs, because I do not think they have good art qualities. There may be others who think and feel much as I do about them—I may even venture to say, I know there are—and I hope they will more fully and ably discuss the question than I am able to do.

Doubtless this letter will bring down the thunders of Mr. Robinson's wrath upon me, if he do not affect to consider it beneath his notice. Had these photographs not been exhibited at the Camera Club, I should probably never have seen them; and if I had, I should not have expressed my opinion of their claims to be considered works of art. An exhibition of "Old Masters" at Burlington House is instructive, and so should one at the Camera Club be. The present one may claim to be that, if it be understood to be an exhibition of what not to do.—I am, yours, &c.

BART ROUS.

The Arts Club, 43, Bloomsbury-square, W.C.

[Do not the generalisations indulged in by Mr. Bart Rous apply with equal force to some of the cartoons of Raphael and other works of acknowledged "Old Masters"?—ED.]

LANDSCAPE ART.

To the Editor.

SIR,—It is exceedingly disagreeable to be obliged to reply again to our Liverpool friend, "F. B." Instead of being duly thankful for the specific information vouchsafed in the article, and to which objection has not been offered by any other person, he has attacked a casual general observation, on which he thinks he has caught the writer tripping. The way this is done would almost lead to the idea that the toes of a great landscape painter had been unintentionally trodden on the tender, corny point; if so it is a pity, as the mere side issue which he raises has been for general purposes sufficiently answered. If the article is worth looking at again, it will be found that the true meaning of the sentences cavilled at is, that since the advent of photography the general taste for, and knowledge of, the aspects of external nature has been so much more widely diffused that the worst, as well as the best, of the painters have been obliged to represent nature or landscape much more truthfully than had been their wont in consequence of the educative influence which photography has exerted upon all—artists as well as the public—who are the purchasers of artists' work, and who will not now submit to receive the productions of the blottesque school either as works of art or as representations of nature. If this has not been made sufficiently clear before, it is to be hoped that it will now be made so, even to the sharp sight of the objector. Doubtless other influences have also been at work in the same direction; even he may have come under them. If "the landscape art" was as highly developed before photography was thought of as it has been since, and as it is now, that may be, and was granted, so far as the mere painting thereof is concerned, but it is an undeniable fact that the careful study of nature was very rarely attempted in the earlier centuries of its practice; and when it was, with the exceptions indicated its more truthful attempts were confined to the schools mentioned—"Holland and the Low Countries."

Nicholas Poussin, one of the most gifted of the French painters, had to seek, or sought, the services of Gerrard Lairesse, of Liège, one of the great Flemish men of his time, to paint his landscape backgrounds, and the result to Lairesse was that his more truthful early work had to be discarded for the fictions of the grand style to please the debased taste of the period. Richard Wilson, who was probably the first British artist who devoted himself to "the landscape art," and than whom there have been few better artists, was so slightly appreciated from the prevalent

ignorance of the public, and his works found so few purchasers, and at such prices, that he practically died of starvation. The public eye and taste had not yet been educated sufficiently to appreciate his attempts at truthfully depicting nature. The well-worn quotation of Sir George Beaumont, the connoisseur, patron, and art critic of his time, may help our friend's memory—"Yes, the picture is good; but where is your brown tree"—and may show the purely conventional notions that existed as to the truthful aspects of nature among the most cultured people of the end of the last, and well into the beginning of this, century; and this ignorance exists among many even to the present day. Witness the comparative failure of the Art Congress which has just been held in Edinburgh, which is reputed to be one of the most artistic cities in the empire, and of which the leading journals say that the last of the Art Congresses have been held. The entire contention is simply that photography has taught, and is teaching, artists and their patrons alike, that truthful representation of the world we live in must be much more carefully attended to than has hitherto been the case. That the extremely modern school of landscape workers now go to nature and patiently study to represent her various phases is only convincing proof of the general accuracy of the statement that photography has revolutionised landscape art. As previously stated, this is perhaps a too sweeping assertion, but is sufficiently to the point, and was never meant to be a tag whereon to hang a dissertation or a discussion.

Relative to what was called the second points of the indictment, where the veracity of my statements were questioned, if the cases quoted are not sufficiently clear, or can in any way be controverted, then, if it should be absolutely necessary, many similar cases can be quoted with all the requisite names and authorities which would convince even the redoubtable champion of landscape art, "F. B." All his verbiage as to "colour," "vegetable life," "line overreaching the sky," "harmonious unity," and the like, has nothing whatever to do with the question, and may be passed over without further notice.

W. H. DAVIES.

THE SURVIVAL OF THE FITTEST—PROFESSIONAL *VERSUS* AMATEUR. TO WHERE ARE WE DRIFTING? TO PERFECTION OR ITS ANTIPODES?

To the Editor.

SIR,—The amount of energy pressed into photography seems to baffle computation, either as to bulk, quality, or count. Forty years ago we only spoke or wrote of excellence of result, but now that the art has reached its jubilee of manhood, it is fashionable to bespatter productions *à la* photographic as the result of "quick exposure," "done by a thirty-shilling set," "So-and-so's first attempt," "done ten o'clock at night by the flash lamp;" and every one of these precious productions so paraded are only fit for the residue box of ashes, and are a disgrace to the art, yet notices of such attempts occupy much of the literature of photographic journalism, and a large amount of wall space at our exhibitions. In looking for the cause, we discover no less than three caterers for this unnatural and undesirable appetite—namely, the publisher, the apparatus maker, and the merchant or dealer. These trio are the nursery wherewith the newly fledged swarm of amateurs assume wings and fly forth to deluge the world with their would-be works of art.

Those whose avocation it is to produce photographic blocks for the printer are much incensed by the rubbishy photographs which are being continually sent to them for reproduction. An architect sends a photograph of a pulpit, the top burnt out, and the lower portion as dark as thunder. We expostulate. He retorts, "Why, I did it myself, and you reproduce it, that's all." An engineer brought us some photographs of machinery, the details of which were hopelessly fogged. In his case he tells us that "they have trained one of their clerks to do the photographing," and he seemed to intimate that my object in complaining was to get hold of the taking of the negatives myself, and of course at a tradesman's scale of charges.

The cry was long and loud, "Oh, if you could only give us a *block* or a *lithographic transfer* direct from the photograph, we will make your fortune for you!" Well, experience has discounted the offer sadly. Now that we can do both, they refuse to supply us with suitable photographs or to pay the cost of their proper production, and hence my query, "To where are we drifting?" A hundred years ago there were pinchback watches. We have now pinchback photographs, and pinchback photographers as a matter of course. I now ask, Can nothing be done to preserve the character of our art? It is manifestly to the advantage of the manufacturer, the engineer, and the architect, that if they wish to reap the full advantages of photography they make a fatal blunder by cheese-paring at the primary step of making the negative. The camera maker assures his customer that a boy or a girl can operate with it to perfection. The dealer warrants his dry plates and patent developer as absolutely self-acting. Turning over the leaves of the latest journal, he points to testimonials of the work done by "some schoolboy who took a medal;"

and so forth. The purchaser believes and pays his money, taking the result as gospel. Now if this easy-going, alip-shod fashion be allowed to go on without effectual protest, it seems evident that photographers who now pride themselves as such will in the near future be ashamed of their connexion with it.—I am, yours, &c.,
JOSEPH LEWIS.

Dublin, November 2, 1889.

To the Editor.

SIR,—Now that a discussion on the relations of an amateur to the profession is fairly afloat, I venture to express the opinion that amateurs generally are too satisfied with their own and their fellows' work. I hold thoroughly the opinion that the best of us amateurs can only approach and not reach the better class of professional work. I say this not out of regard to retouching (for I hate it used on any other than female heads), but because the experience gained by constant practice in lighting, pose, and development, added to the use of the finest lenses, give the best results.

I hold, too, that professional portraits, in differing from our own, are things of such value that when amateurs seek fewer of them of their family and those dear to them than they would were they not amateurs, they make a mistake. So much have I ever felt this, that although I took two-inch heads over thirty years ago, and have by myself scores of portraits of myself and my family, I possess portraits of these by Mayall, Hawkins, and Schultz, of Brighton, Bullock of Leamington, Burton of Leicester, and this year my daughter has sat to Caldwell, of Nottingham, more than once. These things I prize at over twenty times their cost to me, as high class registers of times gone by.—I am, yours, &c.,

W. A.

To the Editor.

SIR,—I was glad to see in your last issue an outspoken letter from a professional photographer. By this, my aim in writing you a letter the previous week was obtained. There are hundreds of men with large interests at stake who feel deeply as Mr. Barnes, of Windsor, the wrong done to them, and it would, I am sure, be well for them to express their views openly as that gentleman has done.

Many so-called amateurs—amongst them your correspondent, Mr. Story—pretend to ignore the fact that the professional man is either injured or thinks he is by amateurism. Let this be settled by a score of traders writing to the journals in the terms they speak to each other and the ground will be cleared. A letter over the signature "Anti-Monopoly" has no covert meaning. It proclaims what the writer thinks amateurs have the right to do, and this is what he and hundreds of others are doing. Let the professionals take his letter as a text and give their views on the subject. The claim of the writer to be considered an amateur seems to be absurd. Your readers may adjudge his claim to be considered a gentleman after they have read the fifth paragraph of his letter to you last week, and so will—

AN AMATEUR.

EXHIBITION MATTERS.

To the Editor.

SIR,—For nearly twenty years now I have journeyed up to town with the double object of keeping old friendships alive and noting the progress made by our best workers. This year my anticipations of a greater treat than ordinary had been stimulated by the various *critiques* of the Exhibition, and also by the many announcements published during the year of new and improved processes, giving the photographer greater power in effectually working our "art-science." The re-adoption, too, of the system of giving medals seemed to point to the present Exhibition being thoroughly representative of the very best that the photographer of to-day can accomplish. I am disappointed. Many of the names of our foremost portraitists are conspicuous by their absence. But not only does the Exhibition suffer from the want of the finest portrait work, the places on the walls are filled by contributors who, whatever may be their other merits, have certainly not done much to assist the Hanging Committee in producing an impressive effect. Instead of the good old English gilt frame which used to be the rule, the cheapest oak mouldings, together with the commonest German, seem to be considered by the majority of the exhibitors good enough to be subjected to the tender mercies of the Committee. I well remember an occasion when I had done my little best by sending about 10*l.* worth of frames to grace the walls of the Exhibition, but, alas! they were returned to me utterly useless. How many others have suffered the same experience? It is very likely, I think, that the dismal and cheap get-up of the present year is due to this cause.

There appears still another reason why first-class men should not trouble themselves to send their work. In a few cases I notice that one man's work is grouped as much as possible together, but this is the exception. Why, if good for one, should it not apply to all? There is very little inducement for most portraitists to send if their works are dotted over the walls here and there. I think there ought to be an understanding that a certain space shall be allotted to each exhibitor, and his works kept

together within that space. I believe that, if they would speak out, such men as Lafayette, Wane, Lafosse, Slingsby, and others have withdrawn in consequence of a grievance of some such sort as the above, and the loss to the profession is great. We are told that progress is being made. Well, I cannot compare the best work of what I may call the old school with that of the new, but I have confidence in asking the old names once again to show if the portraits on the walls of the present Exhibition are really the finest that we can produce, or say if the time has come for a new organisation and a new Exhibition.—I am, yours, &c.,

AN OLD MEDALLIST.

PERMANENCE OF SILVER PRINTS.

To the Editor.

SM,—I should like to raise the question in your columns as to the best means of ensuring greater permanency of "silver" prints on albumenised paper. I feel most keenly this blot on the fair escutcheon of photography, and, as a professional, its serious commercial aspects. No doubt our plate makers have tended to reduce the permanency of silver prints by putting on the market plates that, at best, will only give thin, weak negatives. Then our mount and paper makers are not blameless.

But I would point out a few causes and remedies in my own experience.

(a) Mounting and spotting room being damp. Remedy obvious.

(b) The use of paste without the addition of pure carbolic acid.

(c) The keeping of silver prints by photographers and customers in damp rooms. I always advise customers to keep all their photographs in a really warm living room.

(d) Rolling prints before they are dry (this I found necessary to avoid cracking of the surface of "doubly" albumenised papers) and consequent packing off to customers in a somewhat damp condition. This was done by my assistants without my knowledge, and in a few months I had a large number returned, and covered more or less with spots. I now thoroughly dry each print after rolling—in front of a stove in winter, and in summer by laying out in a warm room.

My own practice is as follows:—1. I avoid too thin negatives. 2. Use a silver bath of at least "60." 3. Only to use the best and most reliable paper, as Tropp's doubly albumenised "permanent pink." 4. Clean pads for frames. 5. Careful washing and "roasting" after hypo. 6. Use good blotting boards, and even then remove as rapidly as possible from blotters. 7. Paste made from Brown & Polson's corn flour (I do not believe in starch), with the addition of pure carbolic acid, and made fresh each day. 8. Only to use mounts of best quality. 9. Rolling before prints are "bone dry," and thoroughly warming and drying after. 10. Only to use a mounting room that is thoroughly warm and dry. 11. Perfect cleanliness all through.

I am also of opinion that "ready" sensitised papers of good quality are more permanent than that sensitised daily by the printer for the day's use, and that prints on "enamelled" mounts are more permanent than those on mounts that are not enamelled. I hope to see some really permanent printing process, as platinotype, in universal use, but as that "won't be yet," I am extremely anxious to make the most of the useful and simple silver print, though personally I prefer the beautiful and artistic platinotype print.

Hoping to see some suggestions from practical photographers, and enclosing my card—I am, yours, &c.,

MORE LIGHT.

A CLAIM.

To the Editor.

SIR,—Having observed recently several suggestions for the use of bisulphites, or "acid" sulphites, mixed with "hyposulphite of soda" (thiosulphate of sodium), for fixing and clearing photographic plates, I wish to direct attention to the fact that this mixture or composition for above and allied purposes forms the subject of a patent taken out by me and completed on December 23, 1887, No. 17,693, and entitled, *Improvements Relating to Means for Fixing and Clearing Photographic Pictures or Images*.

Since the foregoing date the state of my health has largely conduced to the delay in introducing this compound and its functions to photographers. The material, however, will be issued shortly in convenient form by the Platinotype Company, until which time I will not trouble you with further particulars, which would probably savour of an advertisement.—I am, yours, &c.,

HERBERT B. BERKELEY.

NOTTINGHAMSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.—A conversation and exhibition of photographs, cameras, &c., will be held in Castlegate Lecture Hall on Monday, November 11, 1887, Sir John Turney, Knt., presiding, with selections of vocal and instrumental music, lantern display, and shadowgraph. A refreshment buffet. Members' exhibits to be delivered at the Society's Rooms on Saturday evening, November 9, or at the Castle Gate Room on Monday morning before eleven o'clock.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Head and body-rest, two deep 10×8 frames, office copying press; want lens or shutter.—Address, W. C. CHIPPER, 39, Highgate-hill, N.

A Dallmeyer's 2a patent 8½×6½ portrait lens, equal to new, to be exchanged for rapid rectilinear, 20×22.—Address, TAYLOR, Optician, Nottingham.

I will exchange a whole-plate Dallmeyer wide-angle landscape lens for a good lantern, four to six inches condenser.—Address, GILL, 7, Hillside Villas, Hornsey, N.

Will exchange a few books (for amateurs) on photography, also a few cabinet photographs, for fireworks or Godey's *Mechanics*.—Address, J. R. RIGBY, Howick House, Burscough, near Ormskirk.

Will exchange a good violin, bow, case (lock-up), and Farmer's *Instructions*, for good magic lantern, three and a half or four-inch condenser.—Address, W. VARNET, Bridge-street, Buckingham.

Wanted, half-plate bellows camera with double slides, in good condition, for quarter-plate camera and stand and a quantity of Stramonium cigarettes.—Address, JAMES SAVILLE, Sandy-lane, Middleton, Manchester.

Will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY from 1873 to present date (except the year 1885), the *Photographic News* from 1869 to 1886 (except the year 1885), and about a score ALMANACS and Year-books, for good portable apparatus.—Address, HALTON, Photographer, Dowsbury.

Will exchange the first three volumes of the *Amateur Photographer* (complete, unbound), six volumes of THE BRITISH JOURNAL OF PHOTOGRAPHY (1875 to 1880 inclusive, unbound, a few numbers missing), and a quantity of odd numbers of ditto, for Meldola's *Photographic Chemistry* and Emerson's *Naturalistic Photography*.—Address, BAIME, Littlehampton.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPH REGISTERED:—

G. Frost, Alton.—Photograph of Rev. Canon Bernard.

W. W. R.—An eight and a half inch condenser will be necessary; anything less will not answer.

C. BALE.—Foreign matter settling on the paper whilst it is drying no doubt. See answer to "S. R. Stevenson."

J. A. R.—Under-exposure, over-development, with a too great flatness of the lighting, are the faults of the negatives.

J. PORRIT.—1. For printing-out we should recommend you to employ a colloidal-chloride emulsion.—2. Abney's work, *Photography with Emulsions*.

J. VINE.—Messrs. Marion are the agents for the new developing agent, eikonogen. But we believe it may now be had through most of the dealers. If you cannot obtain it in your town, send for it direct.

W. KITMAC.—The second light in the eyes of the sitter is evidently due to a reflected light, but where it proceeds from, of course, we cannot say. When you notice it again, if you cannot detect where it comes from, take the place of your sitter. You will then find out easily enough.

A. SOMERS.—You have been misinformed. The ordinary benzoline of the oil shops will not dissolve indiarubber. Obtain some benzole. This need not be the most expensive kind; the commoner quality answers every purpose, provided its odour is not of much consequence.

YORKS.—Of the two prints sent the bromide one is far better than the platinum. But you must bear in mind that the bromide print is a good one, while the platinum one is an exceedingly poor specimen of what that process is capable of producing. In fact it is a very bad print.

L. R. B.—You have made a mistake in using rapid plates for copying engravings. To obtain the lines as "clear glass," slow plates are best with a developer well restrained. Mawson & Swan's "photo-mechanical plates" are specially prepared for this class of work, and they answer the purpose admirably.

C. BANYARD.—The best lens for large direct heads is either one of the "Group or Universal" series, or one of the "Rapid" type. The latter will answer quite as well as the former, but it is somewhat slower in action. You do not give us any idea of the size head you desire to take, or we would say the most suitable focus lens to employ.

J. S. T.—Neutralise the bichloride of platinum by the addition of a solution of bicarbonate of soda.

JUSTIA.—If the person who engaged you undertook to pay your railway fare and you made the journey, you can recover the amount in the County Court; you can also recover the value of the specimens retained, as well as a week or a month's salary, according to the terms of the agreement, in lieu of notice. We are, of course, supposing the conditions are as you state.

DEALER writes thus: "Is it lawful for a photo-dealer, other than a chemist, to retail such poisons as cyanide of potassium, bichloride of mercury, &c.?"
—No. Any one, except a properly qualified chemist, selling poisons such as those mentioned in the Schedule of the Poisons Act, renders himself liable to heavy penalties. Those named are amongst those included in the Act.

ELSH wishes to know what is a "magazine" camera, and whether it has any relation to the taking of photographs for illustrating magazines.—A magazine camera is one in the interior of which is stored away a supply of plates ready to be used one after the other. There are now many forms of this class of camera in the market, each containing about one dozen plates. They belong for the most part to the hand or detective class, although there is no reason why the magazine system should not be applied to cameras of large dimensions, more especially now that glass plates may be so successfully superseded by celluloid films.

T. B. ALLANSON writes: "Will you kindly inform me through your 'Answers to Correspondents' the best light to employ in taking photographs at night? I have been using one of —'s lamps, but find the shadows are too dense. Should like to know the best way to obviate that."—The best artificial light for photography is the electric arc. Good portraits may, however, be taken with the magnesium light, and the lamp named is as good as any for burning it in the flash form. The dense shadows are to be obviated in several ways—by the judicious use of reflectors, employing two or more lamps, placing the light at a greater distance from the sitter, &c.

LEONI ANGIER.—I. Several articles on artificial light in photography will be found in our last volume, and also in the previous one.—2. No work is published on the methods of painting backgrounds and making accessories. As a rule, photographers prefer to employ those who make a business of this work rather than attempt it themselves. For distemper painting, ordinary dry colours, as sold at the oil shops, and common size are employed; for flattening, the colours as ground for paint are used, the flattening being done with turpentine and colour alone without the addition of oil. Several articles on this subject will be found in back volumes. These you have, no doubt, in the library of your College.

DR. J. L. FLEISHMAN, of Vienna, sends us a letter in imperfect English in which he expresses his indignation somewhat strongly, that one of our contemporaries has spoken of him as a "fictitious individual," seemingly, as he expresses it, "to cast ridicule over another contemporary which does give information over the most advanced science of the day, and which it is conducted by one *reducteur* whose knowledge extends to widest spheres, even also outer spheres."—Dr. Fleishman will kindly excuse us from espousing any quarrel he may have with other journalists. We thank him for his promised article on the *Newest Chemistry*. Will he kindly write it in his native language? We will get it translated.

G. SMITH writes as follows: "1. In THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1888 you recommend a double name alba-carbon light, stopped down with a plate of metal, with an half-inch opening, as an excellent light for enlarging. Will you kindly tell me whether further experience satisfies you as to its superiority over paraffin and other oil lamps? I want to avoid having the latter dangerous lamps if I can.—2. Would the same flame (alba-carbon) used full on without any metal plate do well for showing lantern slides up to a moderate size? We have no facilities here for obtaining oxygen in cylinders, and it is troublesome to make, and I wish (if I can satisfactorily do so) to do away with the danger and stink of mineral oils."—In reply: 1. Yes, decidedly.—2. Yes, provided the flames be kept rather small. Of course, the illumination is not to be compared with the oxy-hydrogen, but it will answer very well for a small screen.

S. R. STEVENSON writes: "Could you oblige me with some suggestion as to the cause of the abominable black spots on the specimens of paper enclosed? The smaller pieces are sensitised, and the portrait fixed—all prepared and sensitised at home on the best paper. The following brief particulars will, perhaps, assist in arriving at a conclusion. The paper is kept flat in a cool room, between boards, under pressure. Several different makes of paper have been tried, but all seem liable. A varnished wood dish, with glass bottom, is used for sensitising, and the sheets drawn over a glass rod; the dish and rod are always well washed both before and after sensitising. The specks do not appear at first, but during drying, and at times are as large as a large pin's head. Sheets which are absolutely free on being taken from the bath, are sometimes covered when dry. The specks seem to attack front and back of paper indiscriminately. Is it possible that minute blacks from a conservatory flue some 30 or 40 yards from the room (and which are occasionally found in the room) could be the cause of the evil? My books state that minute particles of iron in the paper are generally the cause of black specks (Abney, Burton, and others), but makers write me to say this is impossible with their paper. The specks sometimes very much intensify on toning and fixing."—From the fact that the spots appear alike on several different papers, it is pretty clear that the fault does not lie there, and this is further corroborated by the fact that the spots do not make their appearance till some time after sensitising. All the circumstances seem to point to foreign matter, floating particles in the atmosphere settling on the paper while it is drying. We doubt, however, if the "smuts" from the conservatory so far away are the cause. We should rather suspect particles such as pyrogallie acid, sulphate of iron, &c., from the workroom as being the source of the trouble. Thanks for the promised communication.

AFRICA.—1. Any of the published formulae answer very well; we find very little difference with them in practice.—2. Simply by using more or less restrainer, exactly as in the case of pyrogallie acid developer.—3. Certainly.—4. Hydroquinone is now supplied by all dealers, and it is very uniform in quality. Probably in your experiment the plates were over-exposed, or the developer was not sufficiently restrained. A few tentative experiments with the developer will, no doubt, make you *au fait* with its working.

PHOTOGRAPHIC CLUB.—Subject for discussion, Wednesday, November 13, *Copying and Enlarging*.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—Next meeting, Mosley-street Café, Newcastle, Tuesday, November 12. December meeting, Tuesday, December 10.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday, November 14, Mr. A. L. Henderson will exhibit his albums of photographs collected during his recent tour in Australia, &c. This is also a lantern night. Visitors invited.

POLYTECHNIC INSTITUTION.—On Tuesday evening next Mr. Howard Farmer will give the introductory lecture to the special course on the Theory and Technology of Photography. Subject—*The Young Photographer: His Training and Prospects*.

FRENCH EXHIBITION HONOURS.—Among the list of British subjects who receive promotions in, or are nominated to, the Legion of Honour in connexion with the Paris Exhibition we find the names of Mr. Trueman Wood (to be an officer) and Mr. W. England (to be an officer of the Academy).

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Tuesday, November 12, at the Exhibition Gallery, 5A, Pall Mall East, at eight p.m., when the medals awarded will be presented, and papers read by Captain Abney, C.B., R.E., F.R.S., on *The Density of a Negative after Intensification*, and by Mr. W. E. Debenham, on *The Estimation of the Efficacy of Plate Bleaching*.

"A LION STUDY."—Mr. Gambier Bolton writing on this, says: "In thanking you for your very kind and flattering notice of my 'Lion Study' at Pall Mall, I could just mention—to give some sort of idea of the difficulty of this class of work—that I was fifteen hours getting this negative—three consecutive days of five hours each (the limit of time in the Zoo), during which time I could have taken some hundreds of photographs of the lion, but not in the position I had selected. I need scarcely say that it was *not* taken by a hand camera, but with a whole-plate one. I have since then beaten this by taking eighty-four half-plates of a dog's head before getting one that I considered fit to issue in any series of animal studies.

CATALOGUES RECEIVED.—An *Amateur Photographer's Complete Outfit*.—This being a descriptive catalogue and price list of photographic appliances, stereoscopic in the main, although other things are included, manufactured or sold by Mr. W. J. Chadwick, St. Mary's-street, Manchester. We are much pleased to find that Mr. Chadwick has tackled the stereoscopic problem so earnestly. This tractate contains everything requisite in both binocular and monocular photography, in addition to several pages of useful hints. Mr. Chadwick has also sent us a sample of a new form of division for a camera, by which it is immediately converted into a stereoscopic one. This consists of an opaque screen which can remain attached to the front if desired, and be instantly unwound and stepped into its place at the back, being always kept strained within a long focal range by a spring in the interior of the roller in front. This is very useful and effective.

A new catalogue of their celebrated optical productions has been received from Mr. W. Wray, optician, North-hill, Highgate. This contains a full description of the various lenses which this firm manufactures, including rapid and wide-angle rectilinears, casket lenses, single stereoscopic and landscape lenses.

RECEIVED.—Messrs. Mawson & Swan have sent us a photograph of the Lerwick Town Hall, taken on one of their plates at midnight, in June last, by Messrs. Valentine & Co. Lerwick, we may state, is the chief town in the Zetland Isles, and being in a latitude between 60° and 61° it will readily be understood that there is a bright twilight at midnight in the month of June, sufficiently so to enable a photograph to be taken.

FROM the London Stereoscopic Company we have received samples of their new transparent flexible negative films (Carbutt's patent), together with an assortment of Barnett's universal film carriers.

THROUGH Mr. W. Jerome Harrison we have received from Messrs. E. & H. T. Anthony & Co., of New York, a packet of their "climax" films, which, together with those of the Stereoscopic Company, we shall take an early opportunity of trying and reporting upon. This also applies to some samples of Edwards's special transparency plates for lantern slides received from the makers.

LASTLY, Mr. Ethelbert Henry, of Derby, sends for the editorial album four charmingly taken views of exterior and interior of Lichfield Cathedral, including the famous masterpiece of Chantrey's chisel, *The Sleeping Children*. These are beautifully printed in platinum.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1541. VOL. XXXVI.—NOVEMBER 15, 1889.

PHOTOGRAPHING INTERIORS.

No. I.

To produce a really successful photograph of an interior sometimes taxes all the resources of the most experienced practitioner, as the difficulties of standpoint, illumination, and angle of view may all present themselves at once, and in the most exacting form. So many occasions arise when this kind of work is required, that a few general hints will be of service to many of our readers. The first consideration is, naturally, the apparatus,—and here it may be said, that wherever a considerable amount of photographing of this kind is anticipated, the outfit will be of the most expensive, for there is at the outset no use attempting it without a supply of lenses of different foci. Taking, for example, a common size—twelve inches by ten—the outfit should consist of not less than four lenses of six or seven, eight, ten, and twelve inches focus respectively. It would be better to range inch by inch, but the above four may be looked upon as a necessity; for in the majority of cases there will be only one possible standpoint for a given view, and it will almost always be the best policy, whatever the angle embraced, to retire as far as possible, to avoid that strained perspective effect inseparable from views embracing a wide angle. We purposely speak of “strained,” rather than adopt the common form of expression “exaggerated,” perspective, the fact being that if the lenses are of rectilinear type, the pictures they produce would be identical with those which would be obtained by interposing a piece of glass between the spectator’s eye and the view, and drawing lines upon it exactly covering the corresponding lines in the subject to be represented.

Further, it will be absolutely necessary that the lenses be suitable double compounds, and not of the landscape type, which, unless for what may be termed “peeps,” are useless indoors, where straight lines abound in all directions. From the foci indicated it will also be seen that at least the first three, but preferably all, should be of wide-angle type. This is a much-abused term, and notwithstanding the repeated explanations given in these columns and elsewhere, much misunderstood; but for the present purpose it will be sufficient for us to say that any lens capable of taking a satisfactory picture, the longest side of which is more than three-quarters of the equivalent focus, may be classed as a “wide-angle.” This kind of lens also is of a different type, working with narrower apertures, and, in consequence, requiring greater exposure when worked at their quickest. It will be observed that we have given six inches as an alternative minimum, for some makers now advertise their wide-angle lenses to be capable of covering a plate as long as the focus of the lens; and a good lens will do this with a small stop, though the extreme corners

may be open to criticism. Such ranges, however, cannot but be looked upon as straining a lens to its utmost.

We may now pass from the subject of lenses to cameras, and here, undoubtedly, trained judgment must be exercised in selection. Let us say, *en passant*, that we do not by any means suggest a special camera for this work, as one suitable for interiors is also applicable for general exterior and landscape work, though, unfortunately, the converse is not true, for many an old, tried, favourite, outdoor camera will be found wanting when put to the uses we are considering. Still, taking, for example, a “twelve by ten” camera, there are, we may say, many of excellent construction in constant use that will not close sufficiently to allow of the use of a six-inch focus lens, and in some of which even a seven-inch cannot be used. To some extent this difficulty may be encountered successfully, especially when the lens employed is of the portable symmetrical type (the back and front of which are alike), by screwing the lens from the inside of the camera. There is then a gain of the whole length of the lens in approaching the plate. One photographer of our acquaintance possesses a most useful camera, which even this expedient does not quite render serviceable for the purpose; but he has conquered the difficulty by sinking a second flange on the inside of the moveable front; he thus gains the thickness of the wood front, and can then just focus the image on his ground glass when the lens is screwed inside (with, of course, the front pointing inwards).

This point seen to, the means of focussing is next to be looked at. Now all who have experience in this work are uniform in their praise of a camera the ground glass of which is always free from backward projections, *i.e.*, of tailboard or similar structure. The reason of this preference is simple: interior work so often embraces badly illuminated subjects, that when a wide-angle lens is employed it is impossible to get a satisfactory view of the image with the tailboard or other projection preventing the eye being placed in a suitable position for scrutinising it. There are means for partially avoiding the difficulty, which, later, we shall allude to; but unless the back be free and unencumbered, it is impossible to obtain a satisfactory ocular impression of the view on the screen.

This difficulty being overcome by choosing a suitable form of camera, another very grave one is apt to step in. The framework removed from the back of a camera is generally placed to the front, and when the image is focussed an ominous dark patch is seen, which no amount of adjustment will remove when short-focus lenses are used, the framework itself being included in the view embraced. We have seen many excellent pictures spoiled from this cause alone, and it not infrequently happens that, owing to the general obscurity of the image, the

encroachment is not observed till the plate is developing, and it is too late to take other steps. Unfortunately, the effect cannot be eliminated by raising the rising print; for, when straining the powers of the lens to the utmost, its axis must be opposite the middle of the plate. If the camera will not admit it, there is no resource but either to put up with the presence of the encroaching obstacle, or to work always with a camera a size or two larger than necessary, so as to get a free view; though here, again, the difficulty of getting the plate close enough to the lens is almost sure to intervene.

AMATEUR DARK-ROOM APPLIANCES.

No. III.

CIRCUMSTANCES not unfrequently render the construction of an extemporised dark room, either of a fixed or more or less portable character, preferable to the adaptation of an ordinary dwelling room. Such an erection may be for outdoor use, or it may take the form of a cupboard or smaller chamber partitioned off from a larger apartment, in either of which cases it will most probably be a fixture, though easily removeable when required. Or the structure may be of a portable form, to be erected only when required for use, and capable of being stowed away into a small space when out of action.

For the latter purpose, perhaps the most elegant, as well as generally convenient arrangement, is a portable dark tent, as formerly employed for wet-plate work out of doors, of course suitably modified to meet the requirements of dry plates. This is useful not only at home, but may accompany the amateur in his travels abroad, adding little to his baggage, and affording every convenience of a perfect dark room wherever it may be needful to develop or to change plates. Such arrangements are supplied complete by many of the leading dealers and manufacturers, notably by Rouch & Co., who have adapted their well-known "Model" tent to the special requirements of dry-plate workers.

But such contrivances are necessarily comparatively costly on account of the labour and ingenuity expended on the construction in securing the combination of strength and portability. In the same manner that the portable tourists' camera exceeds in price the old "sliding-body" instrument, so the portable dark tent costs more than many an equally efficient arrangement for home use, simply that the amateur may "rig up" himself without much trouble. Portability—that is to say, the degree of portability necessary in a travelling tent—entails the utmost economy of working space; and this needless confinement of the operator may—perhaps undoubtedly does—prove an objection when the tent is only required for home work.

We will suppose, first of all, that the developing room is required for home employment solely, and that it is required to fold up or to stow away into a small space when not in use. To fulfil these conditions in the simplest and most efficient manner, nothing, perhaps, excels an arrangement similar to the old "Sararti" tent of wet-plate days. For outdoor use this consisted of four uprights of bamboo or other light material, jointed for the sake of portability, and braced together when erected by cross pieces reaching diagonally from the ends of the opposite uprights. At a suitable height, a light but strong platform or table, itself folding into sections, was attached to the framework, and the whole, when covered

with opaque material, formed a commodious tent, inside which the operator stood with plenty of room to manipulate the largest plates.

As a travelling tent, Sararti's was principally useful for the larger sizes of plates, owing to the freedom gained by the operator being bodily within the tent instead of inserting only his arms or head and shoulders. But this advantage, of course, brought with it the counterbalancing objection of bulkiness. This objection, however, is of less weight when the tent is only required for home use, and may be considerably reduced, while at the same time adding to the comfort by adopting the sitting instead of the standing position when working. If this be done, the height need not be more than five feet at the utmost, and an internal floor space of three feet square for small plates, and three feet by four for larger sizes, will prove ample.

For the uprights provide eight pieces of bamboo, each two feet six inches in length, and fitting together in pairs, with fishing-rod joints. The upper halves may be of slightly thinner material than the lower, and each should be provided with a short projecting spike on which to fix the cross stays. These consist of two narrow strips of ash or hickory, an inch wide, by a quarter or three-eighths of an inch thick, and of the length of the diagonal of the square. A screw passes through the centre of each, by which they can be clamped firmly together, and in each of the four ends there is a hole, into which the spikes of the uprights fit. One pair of cross stays fixed to the top, and a second at the bottom, or, preferably, as a support for the table, will, when the centre screws are tightened, brace the framework firmly together, and give it great stability.

The table consists of two or three sections of half-inch deal hinged together, so as to fold, for portability's sake, when the arrangement is out of use. The width of the table, or depth from back to front, will depend, to a great extent, upon the bulk of the operator himself, but it should be so arranged that the corners come up to the four uprights, so as to be attachable to them, while the front is hollowed out to receive the operator's body. The height of the table will, of course, be arranged to suit individual convenience.

The covering is made of black twill or silesia, in two or three thicknesses, cut to the exact size of the framework, so as to fit tightly, and so further brace it together. The front is made double, the two portions folding one over the other, so as to exclude light, and fitted with buttons, tapes, or hooks and eyes *inside*, to enable the operator to make all secure. The window will be of the ordinary tent form, and consist of any suitable fabric let into the opaque cover. The sink will be best made of the light and portable form, consisting of rubber cloth stretched on a frame, either fixed or folding, though, of course, if extreme compactness be not a necessity, a stronger wooden sink, such as we have already described, may be utilised. A rubber tube leading into a bucket provides for the waste, while the water supply may be provided for in a variety of ways, either using from a jug, or introducing it from a suitable source outside by means of a flexible tube.

The advantages of such an arrangement as the above are—that it is easily constructed of any convenient size; is strong enough to constitute a permanent dark room within a larger one if desired; or, if necessary, can be erected when required in a few minutes, and taken down in an equally short space of time when done with, and packed into a small compass. It is not by any means too bulky or troublesome to carry about.

when travelling, as the various parts will roll up into a bundle, fastened together with straps, and not greatly exceeding the dimensions of a cricket bag.

THE Paris International Exhibition is now a thing of the past, and, without question, it has, in every respect, been the most successful one that has ever been held. Twenty-five million visitors, without counting some thirty thousand daily free admissions of the exhibitors and their assistants, speaks for itself. With regard to photography, there was nothing very novel shown. But it is gratifying to know that English photography not only held its own, but in some instances took a decided lead, particularly in the higher branches. Those of our older readers who visited the Exhibition of '67—when the late Adam Salomon's famous portraits created such a *furor*—will well remember the sorry figure which British photography cut, particularly in portraiture. In the '78 Exhibition it had to some extent recovered its lost ground. But in the late show English photography decidedly came to the front, as the number of awards prove. The weakest part in British photography, as compared with that of other countries, was in the photo-mechanical department. This is to be regretted, particularly as some of the processes now most employed owe their inception to this country.

Now that platinum-toned silver prints appear to be coming somewhat to the front, several questions have arisen as to whether such prints are permanent, or whether they are really likely to prove more stable than gold-toned ones. Platinum-toned silver prints are scarcely likely by any of our readers to be confounded with "platinotypes," where the image is composed entirely of platinum. Silver prints toned with platinum stand in precisely the same category as similar prints toned with gold. Toning by either method is simply a substitution of a portion of the silver forming the image by gold or by platinum, as the case may be. The question, therefore, is, Will the thin superficial coating of platinum on a basis of silver better resist the action of time than a similar layer of gold under like conditions? This is a debatable point among theorists, which we shall not enter upon here.

THERE is a very good practical reason why the modern-toned platinum prints are likely to prove more permanent than those toned with gold. At the present time gold toning is confined exclusively, or nearly so to albumenised paper. Here, owing to the system of preparing the paper—a thick coating of albumen, lightly salted, and sensitised in a comparatively weak bath—the image is confined almost entirely to the superficial film. Platinum-toned prints, however, are, as a rule, on a matt surface paper; and here the conditions are widely different. The paper is more heavily salted, to begin with; then it is sensitised in a stronger bath. This, however, is not all, for the salting solution is absorbed by the paper itself, and so is the silver solution. Therefore the image is not an attenuated one on its surface, as in the case of albumen, but is a vigorous one in the body of the paper; in fact, the image is composed of a far larger quantity of reduced metal in the latter case than it has in the former. This may be easily demonstrated by tearing a matt surface print and one on albumen. The image of the former will be seen to be of considerable thickness, while the latter is a mere superficial layer in the albumen. Indeed, with some of the more thickly coated papers, the albumen may be removed without leaving scarcely a trace of the image on the paper. It goes without saying that the larger the quantity of metal, whatever it may be, that composes the image, the more there will be to resist deleterious influences.

ONE of the principal reasons why so many of the prints of old—those of thirty or more years back—have stood so well, is due to the then use of very slightly albumenised paper. This was always highly salted and strongly sensitised, so that the image was not, as at the present time, confined simply to the albumen, but was well in the substance of the paper, and then, too, in a good body. As similar conditions to the above exist in the matt paper employed for platinum

toning, we may expect the prints to prove far more permanent than the gold-toned ones on modern albumenised paper.

COLLOTYPE printing is now becoming more recognised in this country as an industry than it was a few years ago. Not long ago machine printing was confined entirely to the Continent, but now most large firms who work collotype employ machines as a cheaper method of production than printing by hand. It may be true that, at present, machine work, unless it is slowly executed, is scarcely equal to that done by a skilful printer with a hand press, but, on the other hand, it is considered quite good enough for commercial work—for trade purposes, for example. This is proved by the number of machines which are now so fully occupied on this class of work. However, we cannot imagine that further improvements will not be forthcoming in collotype machines, and then, perhaps, hand printing will not be considered so much superior. It must be borne in mind that when lithographic machines were first introduced—and collotype machines are very similar in principle and construction—the work done with them was very different in quality from that now produced with the most improved appliances.

WE have just received a letter from a photographer in a large provincial town in the north, asking for information with reference to the number of proofs submitted in different London establishments. He mentions that it has hitherto been his custom to submit only two proofs when a dozen portraits are ordered, but one of his townsmen is now sending three, and another one sometimes four, on approval. He says, on remonstrating with them, he was told that it is the custom in London houses to always send three or four proofs in different *poses*, and even then to give resittings, free of charge, if the pictures are not considered satisfactory. Our correspondent adds that when so many proofs are sent on approval it materially reduces the profits of the photographer, and asks what is the recognised custom with regard to proofs in first-class London houses.

THERE has, apparently, been a growing tendency on the part of photographers to take their sitters in a greater number of *poses* than was formerly the case, and then let them see proofs from all the negatives. Some houses, we are told, at times send out as many as four, five, and even six, different proofs for selection. This practice, of course, considerably enhances the cost of production, and therefore reduces the profits. Whether the practice is good policy or not is certainly open to question. It naturally leads the customer to imagine that the photographer's labour and material can be of little value—by no means a desirable idea to be encouraged.

ON THINGS IN GENERAL.

AMATEUR *versus* Professional polemics are now raging with a fierceness we have not been familiar with for some time, and many hard and true things have been said or will be. Fortunately, however, the true things are not always hard, nor the hard true; a little "give and take" on each side will clear the air, and do good rather than harm from the ventilation of grievances and the provision of that opportunity for a good grumble so dear to the heart of a Briton.

The chief grievances are, first, that many "amateurs" sail under false colours; and, second, that their doings injure the profession. It may be; but professionals should not want to pocket all the pelf and leave to amateurs the trouble and expense of inventing and improving processes which the latter simply exploit when in working order. No one can grumble justly at a rival starting a business in opposition: it is better for him to do it on a small scale and call himself an amateur than to have a man of equal skill starting over the way to "run a studio," and run down prices at the same time. Further, in the former case there is the great advantage of knowing the rival is mean, and of calling him a sneak behind his back, if he be of robust physique. But why this envy, hatred, and uncharitableness? How many amateurs are there in the whole country who can take a decent portrait when asked? Many of them can show one or two such, but

that does not count: "one swallow does not make a summer." Every professional of skill knows that it takes him all his time to keep abreast of the age in variety of pace, excellence of *technique*, and general finish in his work; and it requires time, knowledge, and skill to be able to produce portraits that will possess these qualities, and also be generally liked. The average amateur cannot approach a good professional, and an indifferent worker has no privileges conferred upon him by virtue of his calling. His work must justify his existence. The editorial remarks a short time ago, suggesting to amateurs to remember when they call upon a professional that "time is money," should be laid to heart by all, and much unthinking evil would be avoided. There are, of course, amateurs who go about the country asking permission to change plates, simply for the purpose of seeing all they can and picking up scraps of information. One of this class once called upon me with the plate-changing request, and made an appointment for an hour (fixed for his convenience) when I would have my second dark room ready for his use. He learnt in the course of our talk that this did not involve seeing me at work, nor my usual routine in process of work. He never came at the appointed time, though I went out of my way to prepare. Another wished to engage me to develop some plates for him, and then desired to buy some plates, his "stock being run out." I told him I did not sell plates, but recommended him where to go. He, also, never turned up for me to develop his plates. I did not want to, and he never intended me to; it was simply a *ruse* to know what plates I used, and to have a "look round."

In last week's JOURNAL, among the columns of the amateur fever, appears a letter *in re* exhibitions, suggesting that the various pictures of an exhibitor should be put together instead of being scattered abroad. The idea is good and reasonable, and, though not always possible, might be carried out much more frequently than is the case. Notably at the Pall Mall Show, the works of one gentleman in particular were very badly treated in this respect; they possessed individuality of style and of treatment, and yet scattered about the room their merit was much less conspicuous than would have been the case if they had been placed in one huge frame, which alone at present seems to be the means of keeping one man's work together. But I do not forget the difficulties and anxieties of hanging. The hangers have done their duty this year; another year they may, perhaps, please still more in this regard.

One or two "Answers to Correspondents" lately have shown that the schoolmaster has still to be abroad in regard to matters of copyright; but it is really small wonder that this should be the case, for the small act, covering only three pages of paper in large type, is by no means a model of clearness; it requires much explaining, though its main features are easily enough understood. The main difficulty, however, is the practical remedy, and this is, humanly speaking, so impossible of attainment, that some famous publishing photographers never make their pictures copyright at all. It is certainly very annoying, as has been my own experience, to walk along the streets and see copies of one's own pictures (properly registered in accordance with the Copyright Act) hawked on a barrow at a penny a-piece, or sent you by post with a request to know whether one could supply a gross for seven shillings; but it is just as well to keep down one's cholera, for the man with the barrow snaps his finger at the law, and would have no money to pay costs if even he could be caught and fined. It is well, however, to remember that where copyright is desired, it is purely academical to talk about whom it is inherently vested, for there can be no copyright unless there is a distinct agreement made at the time of purchase to whom the copyright is to belong, and this agreement and its date has to be disclosed to the registration officer. If some change could be made to simplify the proceedings to recover damages or fines, and to alter the wording of the Act, it would be far more useful.

Touching a question of lenses: I notice in an otherwise excellent and readable paper, read at the Birmingham Photographic Society, the statement, "The widest angle lens I have yet met with is four inches focus to the half-plate," &c. Now I have in my own possession a four-inch focus lens which has covered a whole-plate and enabled me to get a good picture very considerably in excess of a half-plate in size; in fact, I can mount nearly the whole of the print from the negative. I append an extract from the catalogue of a

manufacturer of eminence, and others who make lenses of equal power, if they do not claim it for them: "The diameter of the circle illuminated is rather more than double the focus of the lens, and is covered sharply with the smallest stop, equal to $f-64$."

FREE LANCE.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

No. VII.

G. WATMOUGH WEBSTER (No. 87), "*Where's Mother?*"—This is a very quiet picture of a little maiden rising from her sleep and asking for mother. The picture has been well arranged for light and shade, and the young model has done her share in the work very nicely. The lighting and treatment of some white drapery has been very carefully and effectively managed.

Miss Constance Frances (No. 616), *Out-of-door Studios*.—Although these ten small pictures do not merit noticing from the photographic point of view, yet the arrangement of the figures show an artistic capability which, with improved scientific results, would eventually result in some good work in the future.

Rev. C. Hope Sutton (No. 617).—Some exceedingly interesting photographs of the tombs at Thebes. They are, without doubt, worth the study of those learned in Egyptian lore, and show much care and knowledge of the original work in depicting them for historical study.

The transparencies sent in for competition are very good this year, and show how gradually the manipulative skill necessary for such work has produced slides which, when shown on the screen, are veritable pictures. The Society's medal has been awarded to a few slides by E. P. Cembrano, who, in some views of the old Moorish coloured architecture in Spain, has produced picturesque and exceedingly well-manipulated slides, which when enlarged on the screen become most realistic. Probably the most attractive set of transparencies in the Exhibition are those by Mr. George Smith, of the Sioption Company. These, however, were prevented from competing for the medal, inasmuch as the negatives from which they are made were not in all cases taken by the exhibitor. Other transparencies—all of a high average of excellence—are exhibited by F. H. Evans, A. R. Dresser, Major Nott, A. Chancellor, H. Little, T. E. Freshwater, W. S. Anderson, and S. Fry & Co.

In closing our review of this year's Exhibition, we cannot but express the great satisfaction that arises, after a close and careful investigation of both the pictorial and scientific specimens shown, at the great progress that has been made in the quality of the various photographs exhibited—from the pictorial, in a greater latitude in the selection and care in the treatment of subjects—and a far greater evidence of the adaptation of the present method of producing negatives, but more especially in the production of prints by the platinotype process. These scientific investigations in photography are gradually effecting a complete revolution in results; and singular though it may seem, it undoubtedly shows that just as the improvements on the scientific side become more expanded and easier in working, so the attention of the photographer becomes thereby free to bestow his thoughts upon the artistic, and it is now evident that in the future photography must become one of the means whereby art—properly studied—can realise both in figure and landscape subjects much that the most ambitious student could desire to produce; but this can only be realised by those who will devote more of their time and thoughts to that artistic study, without which photography remains but an easy way of recording nothing but uninteresting facts.

This subject is one which should meet with that attentive consideration which the present aspect of photographic capabilities holds out to those who cultivate artistic tendencies.

It is rather singular that so few results have been forthcoming in connexion with the capacity which photography now undoubtedly holds out for the production of unique and interesting studies of figures which the advanced capabilities of mechanical apparatus have brought before our notice. Let us anticipate that viewing the many very clever and amazingly ingenious specimens in that department, which have been one of the attractions of the present Exhibition, that they will result in some interesting studies being forthcoming where

close attention will have been given to artistic results as well as to the simple record of ordinary facts.

This year's Exhibition of the Photographic Society of Great Britain has been one which may justly be looked upon as a fresh epoch in its career; and as possibly a pause in the scientific aspect, as regards modes of production, may be assumed, it only remains for the same capacity and executive skill to be now turned to productions which will show that art can be assimilated with science in the production of works which will redound in the future more and more to a higher status of photographic capacity.

Writing this within a few hours of the closing of the Exhibition, we are enabled to state that the numbers who have passed the turnstile are just about thirteen thousand, and that the amount of money received far exceeds that of any former Exhibition.

ANOTHER CAUSE OF FOG ON DRY PLATES.

I HAVE lately been much troubled with fog on my negatives. This expression will probably raise a smile on the faces of the older photographers, and a sympathetic sigh from the breasts of our more recent neophytes.

I need hardly say that it was not my first acquaintance with this unpleasant visitor, and I was therefore immediately able to determine that its effects had not anything to do with my chemicals, but were apparently due to the action of light.

The fact that the portions of the negative covered by the rebates of the dark slide remained clear conclusively proved also that the illumination of my dark room was not at fault. This practically left nothing to be investigated but the camera and the lens. As I was working with a large single landrap lens, having all the stops turned out, I naturally ascribed the prevalent fog to reflection from the sides of the camera or the edges of the bellows, and I went to some trouble to insert a series of diaphragms in the interior of the camera, but this had no effect on the enemy, who reappeared—sometimes only slightly, sometimes in force. A leakage in the camera was such a natural deduction, that it can hardly be necessary to state that I very quickly reassured myself that such was not the case.

I was now getting fairly interested in the matter, and set to work to really differentiate the results. I was for some time under the impression that there was enough dispersion or aberration from the unstoped lens to cause a general reduction of the surface of the film, as the longer the exposure the greater the fog. This deduction was, however, knocked on the head by my obtaining the worst case of all with an almost instantaneous exposure.

Although pretty confident that a leak was not the cause, still, on no other hypothesis was it to be accounted for, so taking the camera out of doors, I put my head right into it—it is a 12 x 10—and covered up every chink with a voluminous focussing cloth. Needless to say, I found no leak, but my nostrils made me aware of an unpleasant fusty smell in the interior of the camera.

On coming to examine the interior, I found that, through having been stored in a damp place, the paste with which the bellows had been glued up had gone mouldy, and the whole interior of the cloth was covered with a fine growth of one of those virulent hypomyces, or mildews as we generally call them. That this mildew should have any action on the sensitive plate did not occur to me at first. That mildew itself was injurious to dry plates or paper in the long run I knew, but during the two minutes a plate remained uncovered in the camera, it seemed most unlikely that any action could take place, not from contact with the mildew itself, but only from its spores.

However, on going back over my previous experiences, I found that the greatest amount of fog was to be found in those cases where some time had elapsed between drawing the dark slide and uncapping the lens.

But a short time was necessary to test this hypothesis. The camera was conveyed to the dark room, all light excluded, and then sensitive films inserted and left for different times within the body of the closed camera. They were then all developed, together with a piece that had not been in the camera, in the same solution.

To my surprise, all the films that had been in the camera, even that one that had only passed one minute in it, were considerably fogged, varying more or less with the length of their visit. The fogging, too, was of a very considerable extent, far more than could possibly be tolerated on any negative, seriously interfering, indeed, with its printing power.

That the minute spores of this fungus should have such an instantaneous effect on a sensitive plate, I must confess, considerably surprised me. That after a certain time the effect on the plate would

be evident was to be expected, but that the action should be instantaneous will, I think, be novel to most photographers, and may indeed throw some light on the behaviour of dry plates hitherto unexplained.

From a physiological point of view, the action is also extremely interesting. It is evident that since the effect on the film is of the same character as that produced by light, then the destructive action of these hymenomyces is of a deoxidising character. It is also worthy of note that the action of light, which exerts a similar action as they do, should destroy them, for, as far as I can remember, I don't think mould of any sort can exist in the light. It may be, of course, that light has nothing to do with it, but its destruction be simply due to a supply of fresh oxygenated air, that undoes the mischief as fast as it is commenced.

But whatever, however, may be the cause, the fact indubitably remains that a mildewy camera will fog a dry plate as rapidly as an overdose of alkali, and I should advise photographers, therefore, who are troubled with fog, to examine a little into the state of their cameras and double backs.

LYONEL CLARK.

EIKONOGEN.

[A Communication to the Photographic Society of Philadelphia.]

EIKONOGEN is the name of a new developing agent recently placed before the photographic public. It is the patented invention of a Dr. Andriessen, of Berlin, and is a chocolate-coloured powder showing a crystalline formation of a small laminae, and has no taste or odour. It is said to be non-poisonous. It is sparingly soluble in water, about eighteen grains dissolving in an ounce, and forming a solution of a bright grass-green colour. In chemical composition it is said to be an amino-B-naphthol-B-monosulphonate of sodium. It is claimed for this new developer that, while its developing action is much quicker than either pyro or hydroquinone, it brings out the most perfect detail in the picture, even though a very short exposure has been made. It gives a clear negative of a bluish-black colour, and is especially recommended for instantaneous work. It is also said to give excellent results in developing lantern slides and transparencies.

During the past week I have made some few experiments with eikonogen, particularly as a developer for lantern slides, and I propose to discuss briefly this evening the results of these experiments. The developer used was a slight modification of the formula given by the inventor, Dr. Andriessen, that having been found to be almost too strong to give the best results. It was prepared according to the following formula:—

No. 1.

Eikonogen.....	$\frac{1}{2}$ ounce.
Sulphite sodium, crystallised	1 " "
Water	1 pint.

No. 2.

Carbonate sodium, crystallised	$\frac{3}{4}$ ounce.
Water	1 pint.

For normal developer, take of No. 1 and No. 2 each one part; water, two parts.

The results obtained with this developer have so far seemed to justify all that has been said in its favour. Two lantern plates were given the same exposure (a rather short one) upon a given negative, and then placed in separate dishes. To one was added the eikonogen developer mixed as above, to the other a hydroquinone developer prepared with phosphate and carbonate sodium. With the eikonogen the image began to appear in about ten seconds, and in two minutes was fully developed, ready to be washed and fixed. With the hydroquinone developer the image began to appear gradually at the end of the first minute, and at the expiration of five minutes was not fully developed. It required nearly five minutes more to complete the development, and the resulting plate lacked density and detail, and was evidently much under-timed. On the other hand, the plate developed with eikonogen had good density and was full of the most exquisite detail.

The colour of lantern slides produced by eikonogen varies according to the strength of the developer. With the formula previously given, the colour is a clear bluish-black in the deep shadows, graduating down to a beautiful grey in the lighter portions of the picture. If a developer is used containing one-half the quantity of No. 2, and twice as much water, and a longer exposure be given, the tone obtained is much warmer, and is of an olive-brown or grey colour, very soft and pleasing. With both developers the most beautiful detail was obtained, and I consider that, for lantern slides, this developer, when properly used, will give results far superior to those obtained with either hydroquinone or oxalate. These experiments were merely tentative, and more familiarity with this new agent, and possibly

some modification in the formulæ, will be required before the best results can be obtained. It works quickly, does not stain the film, and can be used for a number of plates before becoming exhausted. The six lantern slides I show you this evening were developed with one ounce of this developer, and with the last plate it showed no signs of exhaustion.

As a developer for negatives and instantaneous work, eikonogen will probably prove as excellent as it has for lantern slides. The negatives I show you now were made this afternoon about four p.m. with a Hawk-eye camera, using Cramer plates, sensitometer 35. Although the light was rather weak, and the plates not very fast, I think you will find that they show excellent detail, and seem, if anything, to appear a little over-timed. I am now experimenting with eikonogen as a developer for negatives, and especially instantaneous work, and trust to make a further report at some future meeting.

As far as its price and developing power are concerned, it is probably quite as cheap, if not cheaper, than pyro. It costs now about forty cents per ounce, and in developing power it will probably go much further than the pyro, while as an additional attraction it does not become dark and discoloured, nor will it stain the fingers, and hence will be much preferred by the amateur.

As a developing agent, I believe that eikonogen has come to stay; and where its use is fully understood, I believe it will be found to be the most formidable rival to pyro that has yet appeared.

CHARLES L. MITCHELL, M.D.

THE IMPROVEMENT OF FAULTY NEGATIVES.

It frequently happens, no matter whether the operator be professional or amateur, that in the course of their working they meet with annoying cases of eyesores—faults or failures in the negatives they produce. Who cannot bring to remembrance some negative which has caused them to ejaculate, "If it were not for just this or that it would otherwise be a perfect result?" As a rule, the sound old standing advice holds good, viz., that of taking a new negative, but as it very frequently happens that the opportunity is not forthcoming for a fresh exposure, the operator is compelled just to battle with what he has got and make the best of it. Then follows his having recourse to some means of doctoring, whereby the eye-ore, fault, or flaw, of whatever form the failure should happen to assume, is minimised or removed altogether. So numerous and varied are the troubles met with in this respect, that it is not always an easy matter for an operator to make up his mind as to what, under the circumstances, is the best course to follow. As a rule, however, I think it will be found that these defects may be divided into two classes, viz., those caused by some overlook or error on the part of the operator, and those defects inherent in the sensitive plate, over which the operator when working has really no control.

I propose to deal, first, with a few cases of the former class, viz., those cases for which the operator is responsible. As I write, I have before me a very glaring case of this kind; it is the negative of a lady. This plate is perfect in almost every respect in the way of lighting, expression, exposure, development, &c., but, unfortunately, in the posing an error was committed which entirely mars all the rest, causing as it does a very noticeable eyesore. I have said in this case that the fault lay in the posing, this has been done by so turning the head that the off ear projects beyond the line of the cheek, and is just a case in point, showing as it does how a careful operator, by dint of a little forethought, can so deal with weak points in a sitter's appearance as to considerably assist towards the production of an harmonious picture. Here, undoubtedly, the worst point with this sitter was the unusually large ears, and when such are met with, it is just about almost certain they will be found to have a tendency to droop or fall forward. This is just what took place in this instance, this leaning forward taking such a shape as to spoil the contour of the face.

Now here we have, when viewing the negative, a dark deposit relieved by a light background, and the question comes to be, "How is the objectionable dark deposit to be got rid of?" Some may imagine that in such a case a clever modeller would have no hesitation in having recourse to a scalpel, and with its aid remove the eyesore; but where is the average professional retoucher, I ask, who would care to trust himself with such an operation? not to speak of the vast army of amateurs who know really nothing about the use of the knife or pencil, as practised by an expert modeller. Doubtless in many instances the knife becomes a very handy tool to use in cases where the flaw or fault lies on the surface, such as slight flashes of fog, &c. (and to this I hope to refer later on), but in cases like the one we are considering, where the dark deposit has entered and gone

deep down into the film, but few experts with the knife would be found so bold as to use it in such an instance. Therefore, some other means must be devised for the removal of the eyesore, if the negative in question is to be utilised.

Having referred to a case in point where the fault lies in the shape of an opaque deposit in the film, I may remark that, as a rule, most flaws of this class generally assume one of two forms, viz., they either appear in the negative as opaque or transparent, and but little consideration will be required at the hands of my readers to understand that the treatment of a case of transparency must differ widely from a case of opacity. At all times I think it will be found that even an average worker has but little hesitation in tackling a transparent flaw in a negative, for it is so easy to spot or block out with the aid of pencil or brush any little defect, and then work up its surroundings with the pencil, so as to make its appearance non-observable in the finished print. Not so, however, with opaque markings; it is in such cases that I have invariably noticed my pupils seem completely balled in their ideas as to how they are to get rid of them, and, doubtless, many are the cases where good negatives are discarded entirely, just through such opaque flaws being found by amateurs in their results. They get an idea in their heads that such faults are incurable, and, in many instances, when observed on development, they simply consign the negative at once to the ash pit, and make up their mind to try again, expecting better luck next time.

In my next, I hope to refer to a method of treating negatives containing opaque flaws, whereby any average worker can so set about the operation as to materially improve the same, if not to entirely remove the fault.

T. N. ARMSTRONG.

COLOURED PHOTOGRAPHS.

XIII.

In our last paper we treated on the general posing of the head and figure. The next point to claim attention is the dress or costume. This is a much more weighty consideration than may appear possible at first sight. Believe me, there is considerable artistic taste required, not only in the selection, but also in the general disposition, of what we may comprehensively term the *draperies*. There are many who treat this portion of their picture, in conjunction with the *background*, as quite a secondary consideration. This is, however, a mistake, as will be seen by observing any of the masterpieces of our best painters. There is no end of artistic skill and feeling expended in the working out of these points, and truly some of the best qualities of many acknowledged gems in portraiture are dependent upon their successful treatment.

There are many forms of dress which to us appear absurd and almost ludicrous, yet in their own day were the very height of fashion, and looked upon as the acme of all that was beautiful. The same feelings that we have to-day regarding the costumes of twenty years ago will, no doubt, be entertained regarding ourselves by those who will follow us twenty years hence. What changes have not come to pass during the last twenty or thirty years in this department! Take the bonnet, for example. See what a whole line of bonnets may be traced between the aristocratic coal-box of years gone by and that wonderful head-gear which rules the fashion to-day, and which may be a hat or bonnet at will. I am always making mistakes, although I should not; for my lady friends tell me that a *bonnet* has *strings* and a *hat* has *not*. This is a nice distinction.

The form of dress, too, of both ladies and gentlemen has undergone no end of changes. We have had the long waist, the short waist, the no waist at all; wide, flowing sleeves, as if material did not cost anything; then the tight ones, as if we could not get another sixteenth part of an inch more to save our lives. How often have we laughed at some of the portraits of our ancestors, as handed down by the portrait painters of bygone days. Some we have absolutely thought *frights*, yet we will in a future generation appear just as ridiculous to those that come after us. All this is not owing to the innate absurdity of the costume, but to the fact that the eye is not accustomed to it. I have a photograph of H.R.H. the Princess of Wales, taken during the reign of the *turban hat* and worst form of *crinoline*, and really one can scarcely believe one's eyes. It is really hard to imagine that this photograph is a faithful representation of one whom to-day we all regard, and justly so, as the most graceful and best-dressed lady in the land. As she is now, so was she then. It is only the change of fashion that causes us to smile at the records of the past. I only mention this matter so that we may never be led into extremes when painting a portrait, but rather try to make our costumes as little assertive as possible.

Beyond a doubt we should endeavour to secure an arrangement of

dress that would not too clearly carry a date with it. Any dress which gracefully indicates but does not display the form of the sitter, must necessarily be the most acceptable. Such a dress can never be, as it were, entirely out of fashion, and per consequence look ridiculous. It is never well, too, to overload your costumes with ornaments. Of course, these remarks are mainly applicable to portraits of ladies. If ladies intend having a portrait painted, I would always advise them to let the artist who is to paint it arrange as to the dress to be worn; and if to be photographed first and painted after, he might come to an amicable understanding with the operator, who, if an artist himself, will duly appreciate his suggestions.

I think there is more taste generally to be found among the wealthy classes of to-day than there used to be; a painter has not to struggle to produce a satisfactory harmony between all the most glaring colours, as was the case in the olden times. So much for the general dissemination of art principles, which have had a beneficial effect upon the arrangement of the colours and contrasts even of an every-day costume. I think I can do no better than advise all who have to paint coloured draperies to make a study of the portraits by Sir Joshua Reynolds and, perhaps, Vandyck. There are no better examples, that I know of, to illustrate the most artistic and harmonious arrangement of colours in regard to draperies and backgrounds.

If we visit the National Gallery and other important collections of the best works of art, we will find, as a rule, that in the works of Rubens, Vandyck, Rembrandt, Correggio, Murillo, and Velasquez, and a host of other great painters, white is always placed next the skin of women and children. It will be remarked that Sir Joshua Reynolds was rather partial to dressing his children and ladies in white muslin, or, if not, in some light drapery of a more or less warm neutral tint. For strong colouring we must turn to his portraits of men, who in those days disported themselves in much more lively colours than they do to-day.

It will be found on examination that Vandyck used more positive colours in his pictures than did Sir Joshua Reynolds. It was nothing unusual for him to introduce the three primary colours—red, blue, and yellow—and supplement them by the tertiary neutrals (drabs and browns). Green and purple do not seem to be such favourites with him, but he has introduced some very splendid orange-coloured draperies, and has heightened them in tone until they almost became scarlet, and these he contrasted with blue.

As everybody knows, blue is a very favourite colour with the ladies, but to a young painter there is nothing much more difficult than to skilfully and successfully arrange a quantity of this cold and not over-sympathetic colour. Sir Joshua has left it to us as his opinion, and I don't think we could have a better, that the principal lights in a picture should be of the warm and mellow kind, such as reds and yellows. As is usual when one great man lays down a certain principle, another great one tries to prove it wrong, or, at least, not altogether right. So it was with this theory; it excited a desire in the mind of the mighty Gainsborough to prove its fallacy. The result was that he painted his justly celebrated picture in the Grosvenor Gallery, which is known to all fame as the *Blue Boy*. Most people who take an interest in art have heard of, and perhaps seen, this splendid work. It is a full-length of a little boy in a blue satin dress, the adjacent colours being a variety of warm and rich browns. It was quite the topic of the time in artistic circles, and many leading artists considered that he had successfully refuted Sir Joshua's theory. This opinion, however, was not shared by Sir Thomas Lawrence, who considered that Gainsborough only succeeded partially—that the difficulty was grappled with, but not surmounted.

I do not think any portraits will be found more instructive than those by Vandyck; we may as well, then, consider how he treated this colour whenever he was obliged to use it in any of his draperies. He invariably placed linen next to the skin, and contrasted the blue with warm browns. Into the same picture he usually introduced a red, or, if not, an amber-coloured curtain, and often an armchair or other drapery of the third primitive colour. In this manner he maintained a perfect balance of the warm and cold colours, and harmonised the whole picture by a skilful use of the warm browns and greys. It will be remarked that he often, too, introduced a *drab* scarf on the neck of some of his figures, but I have no doubt this was done in order to give value to the tints of the flesh.

Rembrandt usually concentrated the light on the upper part of his figures. It may be to carry this out successfully that he showed such a marked partiality for black draperies.

The next point to require consideration is the general arrangement of light. In this the artistic feeling of an operator can be exercised to the fullest. Of course, when we are given a photograph to paint upon, we must be contented and go ahead upon what we have before

us, but still it may be useful to know what we should do if not so aided. As a rule, it will be found that most studios are lighted from above. It is considered advisable that the light should enter the studio of the painter from a window at least six feet from the ground. This is in order to throw all the shadows downwards. In the case of ordinary windows, an arrangement can be put up which will have the desired effect. A moveable shutter, or dark blind, pulled up and down by means of a rope and pulley, would not be very difficult to fix up, and would be found to suit the required purpose. In arranging the light, it should be so directed as to secure the greatest possible breadth of effect. If the face be turned to the light, the shadow of the nose must be more than ordinarily deep, or else it will lack its due prominence. In such cases, too, a dark background will be found advantageous in order to give a general tenderness to the other side of the face. This latter arrangement is sometimes found in really good pictures, but, as a rule, the first-mentioned position is the one most generally selected. What I am going to say is, I fear, already known to all, namely, that the painter should sit in such a position that the light should enter from his left.

The figure is the next study which we must consider. As with the face, so with the figure, when we have a photographic base to work upon. It is well, however, to know just a little of what we would have to do if we had to paint the picture unaided. It is just in this regard that a photograph is so useful. There is nothing of such importance as a good and correct *outline*, for it is the foundation, as it were, of the entire picture. For this purpose, what a help is photography! for where is the artist's sketch that will be so true and full of detail as is the photograph?

It is never well to make our sketch on the paper direct that we intend to colour upon. If we do we are likely, in rubbing out and making corrections, to injure the surface upon which we have to work, and this would greatly injure the quality of our picture when finished. It is better, then, to make our sketch on another piece of paper, and then transfer it by tracing on to the stained paper which is ready for colouring. In making a sketch of a head, we should, in the first place, draw a line to mark the natural inclination of the head. If we are about to draw a full face, this line will be straight; if three-quarter face, it will be somewhat curved. Then draw a line crossing the first exactly at right angles, which will indicate where the eyes are to be placed. Also sketch lightly another line or two below this to show where the nose, mouth, and chin are to be. No one should neglect this rule, as on it depends the truth and solidity of our future picture. Without taking these precautions we are likely to get our mouth and nose awry, and our eyes on anything but the same plane. Having these lines, however, as a base, we can block out the various features with a certain freedom. Care should be taken to place them in their true positions, just proportions, and having due regard for the governing influence of perspective. Having thus marked in the general form, we must again go over the drawing, carefully giving every feature its true form and natural expression. A good way to judge if our drawing be good is to hold it before a looking glass, and if there be any bad drawing it will at once strike the eye.

When we are perfectly satisfied with the correctness of this drawing we can place a sheet of French tracing paper over it, and then mark out the drawing either with a pencil or a brush dipped in water colour. This done, take a sheet of tissue paper rubbed over with charcoal, or powdered red ochre, and place it on the stained paper, powdered side down, over it place the tracing, and, having fastened the corners so it cannot change its position, proceed to pass over the outline with an ivory or agate style, lifting the corners occasionally to see if we are getting on all right. The style must be used with sufficient firmness to secure a mark, but not in any way to indent the paper. When all the lines are secured we can take off our tracing paper and the one with the powder; we must then proceed to strengthen and correct with a fine-pointed pencil, beginning at the lower right-hand corner in order to avoid any chance of the hand obliterating any of the tracing. Having thus secured the entire drawing, dust off the remnants of the powder, or charcoal, by flapping the paper with a clean and soft cloth. This completed we are ready to begin our colouring, and will try to produce a work of art, whether it be on our own sketch or a photographic base.

REDMOND BARRETT.

PROFESSOR LUCKHARDT ON NEGATIVE RETOUCHING.

THE following data are gathered from the lecture delivered by Professor Luckhardt at the Amateur Club of Vienna, on October 12 last:—

The arrangement of the retouching table, above all things, is of an importance which cannot be too highly estimated. It is suggested that it should be so constructed that the operator should receive all

the light through the negative; and, in accordance with this rule, besides a shade of sufficient size advancing the required distance above and in front of the operator's head, a black background should be provided behind, so as to intercept any reflected light.

The retouching table should also, to protect the eyes, be furnished with a blue glass, of the same colour as ordinary eye-protecting spectacles, whereon the negatives under operation may be placed. A piece of light-green or light-blue paper, too, will prove a good substitute for the reflecting mirror. A turning-plate should further be arranged to enable the position of the negative to be altered as required, whereby "hatchings" will especially be facilitated, no matter whether they are made with a pencil or a Nadel needle.

Not only should every retoucher of negatives possess some preliminary knowledge of the anatomical relation between the various parts of the body or head (a knowledge acquired by practising figure drawing and by a careful inspection of picture galleries), but it is also essential for a beginner *not* to confine himself to work with negatives, but from time to time to operate on positive copies as well, so as to exercise his eye and prevent it from becoming one-sided. To all inquiries addressed to the lecturer with regard to the method of becoming proficient in retouching, he invariably directed the attention of the querists to the importance of *cultivating the taste*, which is only feasible by dint of a frequent and attentive examination of pictures, and of constant practice in drawing from good models.

It is also advisable to cover the negative with a "mask," with an opening of about the size of half-a-crown, whereby the work is materially facilitated, while, on the other hand, such a mask affords additional protection to the eyes, inasmuch as it counteracts the dazzling effect of the light. A rough print should in every instance be given to the retoucher, so that, on the one hand, he may guard against any mistake in regard to outline, and, on the other hand, avoid producing wrong effects in modelling. The comparison of a retouched negative with an unretouched print should in no case be omitted, as it enables the operator to control his own work.

An excellent method of practising the art of retouching for a beginner is this: He should take a negative containing a scale of various shades—somewhat like a photometer—and retouch the lightest shade, so that, when printed off, it may produce the same effect as the next darker shade. This is all the more essential, as differences of shade in the negative—such as are almost imperceptible to the eye—will distinctly show in a print, owing to the difference in the extent to which actinic light is admitted through the colour, nay, even through the pencil marks. The great mystery in retouching lies in always observing the right proportions in endeavouring to increase the artistic effect; and, to be able to do so, it is necessary for the retoucher to be able to tell, from the mere inspection of a rough print, what features are characteristic, and what is simply the result of accident or an incorrect representation of the respective value of the colours by the chemical process. A yellow shade in the skin, for instance, often looks like a cavity, and thus interferes with the working up.

In most cases the negative should only be covered with a film of varnish, or simply of a solution of gum, and should the film interfere with the work of the pencil, the part to be operated upon may be rubbed over with oleine. This course should, however, be avoided as much as possible, as not only does it affect the neatness of the negative, but it also causes the silver of the paper to stick and alters the retouching. There is, at present, a special negative lac in the market which generally requires no subsequent preparation before it can be operated upon with the pencil; but in case it should not prove quite serviceable at once, the portion to be retouched may conveniently be rubbed over with powdered pumice stone or "ossa sepiæ." To protect the retouching, the negative can also be, in the first place, covered with ordinary amber lac, then retouched, and, lastly, receive a coating of ordinary varnish.

When it is necessary to go over the negative with the eraser, this should be done with the least possible delay, before the coating dries and hardens, or the lac may be rendered elastic by the addition of a little castor oil.

Retouching may also be considered as including methods of obtaining, by optical means, delicacy of outline and equality in tint. For instance, after accurate focussing, one may employ the whole of the lens, and during the exposure introduce a small diaphragm, which is most easily done by means of a clip-diaphragm. Denier, in St. Petersburg, is said to have caused a vibrating action of the air by placing a spirit lamp in front of the objective.

It is often necessary, in the case of portrait and landscape negatives, to cover the back of the plate with translucent lac or coloured collodion.

INSTRUCTING THE PUBLIC.

THE people need instruction as well as the photographers. There are many writers on their duties and obligations. "How and where shall I get a good picture?" is the question often asked by persons intending to sit. They desire a good picture, and should be told how to get it. And yet there are so many people this year that the attempt to instruct all of them seems a large contract. In an address in the Academy of Music at St. Louis, I said, "Go to a man of well-known ability—a man of taste, who has a reputation for reliability—pay him his price, and do not patronise the meaner man around the corner because he gives you a larger lot of trash for smaller amount of money." This advice carried out would ensure the sitter good, and, in most instances, satisfactory work.

A large number of people seem to think a photograph is only a photograph, and it makes no difference who takes it. A greater mistake was never made. The results are as wide apart as the poles. One man poses your face to the best advantage, sees that the light and shades are right, and manages to get your best expression; the other tells you to sit down and keep still, and does not trouble himself about anything, except to open and shut his camera, and you are dismissed with the assurance that it is all right and "looks just like you." When the so-called pictures are received, you feel like committing suicide if you look like that, and perhaps you would be justified in doing so.

A good story is told of Mr. Lincoln. He was in the woods gunning, and meeting a stranger on the same errand, the man raised his gun and pointed it at Mr. Lincoln. "What are you going to shoot me for?" was the inquiry. "Because," said the man, "I was always told if I met a homelier man than myself to shoot him." "Well," said Abe, looking at him, "if I am homelier than you are, *blaze away!*"

Further, the man you patronise should be a man of truth and veracity, that you may rely on what he promises, and one who feels that your future patronage depends on the quality of his work. Tell him if they finish well to send you two or three dozen, and he will see to it that they are right.

Again, always dress and wear your hair as you are accustomed to do. Do not go to a hairdresser and disguise yourself by being "done up" as you never appeared before. Your own husband and children would hardly know you with those extra puffs and furbelows. Just try and *look like yourself*, and then the well-executed picture will look like you. It will be worth your having, and a pleasure to your friends.

If people would use the same amount of judgment in getting a picture that they do in buying a watch, good results would follow. When you buy a watch, do you go to a Chatham-street old clothes dealer, who in loud tones declares "it is de finest watch in der city," or do you go to a house of reputation, where you can be sure of getting a reliable watch?

Do not show your proofs to everybody for an opinion. Often they are submitted to the cook in the kitchen, and then all the way up to grandma in her specs, and perhaps the first opinion given is acquiesced in by all the crowd—"It don't look a mite look you!" or if the likeness is conceded they will select the one in which the dress is most satisfactory, and you may get the best-appearing dress and the poorest face. Let your photographer decide which will finish the best.

It is not desirable to be in a hurry to have your pictures finished. It does not require much hurry to spoil what would otherwise be a good picture. Any one part of the process slighted by too much haste makes the entire operation imperfect. All of us photographers have yet much to learn, so do not hurry us, but give us time to do what we have learned to the best of our ability.

It is well not to have your expectations raised too high. People sometimes imagine that by some incomprehensible means the skilful artist is going to furnish them with pictures that are a great improvement on nature. Some faces do photograph better than they are in reality, but they are very few. The skilful artist can and will help things by careful retouching. He can remove the frown that should never have been there. He can take out the strong lines if any are there. He can straighten mouths that are awry because of the continued use of "chewing gum," or *some other cause*. But do not let him do too much, or your nearest friend may ask "who the picture is intended to represent?"

"I always go to the best photographer," says one, "yet my pictures are never so good as Amy Brunett's; hers are always good." That may be so; her face is strongly marked, her features regular, her eyes black, and eyebrows strong, and more, she has perfect control of her expression; while your eyes are light blue, eyebrows very light, or perhaps white, and when you sit for your picture you lose all control of your expression. There is an old saying, "It takes *two* to make a

bargain;" as I have before said, it also takes two to make a picture. The operator cannot do it all; you must do your part in the very important part of keeping an expression. The capable operator will exert himself to obtain your best. You must neither look as cross as if you were angry at yourself and "the rest of mankind," nor smile so much as to look silly.

It has been remarked that some persons are most desirous of getting a pretty picture than they are of getting a good likeness, and there are cases where the beauty is in the form, the vivacity, the behaviour, or the tasty dress, but, alas! not in the face. Unfortunately many of us are not born either rich or handsome. The "biddy" with red blotches on her face said "beauty was only skin deep." When mouths and noses were given out, some of us seem to have received more than our share, and you and I must be content if we hold position with the general average.

A. BOGARDUS.

—Con. Number St. Louis Photographer.

Foreign Notes and News.

THE remnants of the Berlin Jubilee Exhibition have been removed to Königsberg, where a three weeks' subsidiary Exhibition is being held under the patronage of the Hereditary Princess of Sachsen-Meiningen, who figured as the protecting deity of the Berlin Exhibition. This exalted personage has recently written to the committee to express her sense of the advantages derived by the Exhibition from their indefatigable exertions, an opinion in which any who have practical experience of the difficulty attending the organization of undertakings of such magnitude will doubtless re-echo. Her Royal Highness further regrets that she was unable to pay the Exhibition a personal visit, but states that she has been sufficiently kept *au courant* by the copious reports furnished her by Dr. Vogel. The German periodicals have been unanimous in attributing a large share of the success of the Exhibition to its having taken place under the patronage of so distinguished a lady. Happy country in which such august personages take interest in matters photographic, and succeed in ensuring the success of exhibitions at such a small expenditure of personal energy!

HER ROYAL HIGHNESS also sends her congratulations to Dr. Vogel on his receiving the "prize of honour" from the Committee—congratulations in which readers of the JOURNAL will heartily concur, as Dr. Vogel's great services to photography are probably as fully appreciated in this country and America as they are in his native land.

THE following method of making a permanent, colourless hydroquinone solution is given by M. Pétry in the *Progrès Photographique*, and appears to be thought well of on the Continent. 40 grammes chemically pure sodium sulphite are powdered in a porcelain dish, and 80 grammes carbonate of soda in another dish; 8 grammes of hydroquinone are placed in a litre flask, and the powdered sodium sulphite and sodium carbonate are added to it quite dry. The salts are mixed by shaking the flask, when it is filled up with rain water and shaken till solution is complete. M. Pétry adds that by momentarily immersing a gelatine plate in this developer and drying in the dark its sensibility is considerably increased.

THE civil courts of Berlin have appointed Herr H. Riffarth, the owner of a well-known photographic establishment in that city, to the post of legal specialist in all matters connected with photographic printing. No better proof could be needed of the constantly increasing importance of photography in all departments of civilised life.

THE wonderfully successful photographs of wild animals, apparently taken in their native fastnesses, which from time to time issue from the camera of the indefatigable Anschütz, may not be as well known in this country as in Germany; but any who have seen them will be willing to admit that the science of zoology owes almost as much to his untiring energy as does the art of photography. The way Herr Anschütz goes to work is a proof, if any were needed, that he does not stick at expenditure to attain results. In the Zoological Garden at Breslau he has had a large den of 140 square metres extent built at his own cost, enclosed by walls some 6 metres high. Its surface is strewn with pebbles, blocks of stone, trees, plants, &c., which are varied with the nature of the beasts to be "taken." The walls are adorned with suitable landscapes. Into this *plateau* the animals to be photographed are driven, and permitted to remain there sufficiently long to make themselves thoroughly at home, whereupon a suitable moment is awaited for obtaining an impression by means of a camera inserted through an opening in the wall. The amount of patience required in awaiting a suitable opportunity, the various dodges and devices required for fixing the attention of the

animals and inducing them to assume suitable positions, are more easily imagined than described, but that Herr Anschütz succeeds in surmounting them with signal success will be admitted by all who have seen his unequalled results.

DR. STOLZE'S *Photographische Nachrichten* remarks, *apropos* of Newcomb's receipt for a monochromatic flash light, viz., five to seven of nitrate of soda and one part magnesium powder, that the proportion of nitre is much too high, for in the case of the much more energetically acting chlorate of potash three parts of the latter to one of magnesium burned only with difficulty, and by no means instantaneously, the excess of potash acting as an inert mass interfering with the combustion. The best light was obtained with equal proportions of magnesium and chlorate of potash. It would, therefore, appear advisable to employ not more than those proportions when making a flash-light mixture of magnesium and nitrate of potash.

THE same periodical points out that in regard to testing orthochromatic plates by means of Warnerke's sensitizer, it is only the sensitiveness for blue, and not for yellow, that is registered. As good orthochromatic plates are from ten to twelve times more sensitive for yellow rays than blue, it is important to bear this fact in mind.

AN illustration in the *Photographische Mittheilungen* serves to point out a rather curious fact in instantaneous photography. The illustration given is that of a photograph of a passing bicyclist, in which the time of exposure was evidently too long. The image was, as a necessary consequence, blurred—all except the spokes in the lower portion of each wheel, which came out comparatively distinct. It would be interesting to know if readers of the JOURNAL have noticed anything similar.

THE GROTTTO OF HANS.*

ONE naturally thinks of a grotto as some place where pretty stones, shells, &c., can be seen; but little did I think I should go through a series of halls—fourteen in number—many the size of small theatres and concert rooms, and one larger than the Albert Hall, all hewn and formed by nature, and by her decorated in such a way that no artist could imitate. The names of the halls convey some idea of the leading characteristic, and it does not require much fancy to connect them with the subject of the title; they are as follows:—

Antiparos, Priapee, Scarabees, The Foxes, St. Nicholas, The Frogs, Vigneron, The Gulfs (Holes), Mamelon, Vault of the Lance, Alhambra, Marvellous, Mysterious, Boudoir de Proserpine.

These halls were reached by magnificent terraces hung with draperies of such delicate and exquisite design that nature, as if by magic, touches man's brain and quickens his imagination in order to perceive at a glance how great an artist it would be possible to become, either by the wonderful agency of light and photography, or by the skilful movement of his hand and brush. We had passed through some pleasant stages of excitement and surprise, but had now reached a point, the solemnity and impressiveness of which bade every heart be still. We were standing in the cathedral upon its solid floor and beneath its majestic dome, whose height no building ever made by hands had reached, and whose boundaries from wall to wall were past the power of our vision to discern. On one side stood the organ, stalactite and stalagmite combined, fluting upwards and downwards in beautiful and perfect symmetry of form, awaiting only a seraph hand to set its music floating through the lofty vaults above, while ranged before it stood the company of spell-bound souls lost in an effort to realise the majesty and vastness of the wonderful surroundings. Notwithstanding this, the climax of immensity was not yet reached, for we were led on by our sturdy guide through corridors and passages, ascending and descending by rugged paths and steep inclines, by steps and stepping stones, or by sudden and eccentric turns, always lighting on something new to stimulate our wonder and excite our admiration, when, lo! we have arrived within the Hall of Mystery. The Mysterious was indeed attested by the breathless awe that overcame the party, and it is difficult to describe the weird sensation forced upon us, completely shut out as we were from the world with its glorious light and life. The impenetrable space and darkness was only made more noticeable by the lights carried by our lamp bearers, for the illumination seemed only a tiny spot of ground beneath our feet, while beyond us on every side the unknown distance, and the cold and dismal gloom were elements of awe and fear. Here, however, in this hopeless, cheerless, boundless place (thanks to our indefatigable guide) we had the highest entertainment of all during our journey in the caves. Strong in the determination to please, as well as strong in limb, he left us for a little while, and then divesting himself of his coat and taking a hempen string from his girdle, he lit his torch made of it and paraffin, and leaped and bounded up the rocks 200 feet or more. Here at the summit, standing like a spectre amid the surroundings that would be considered elsewhere supernatural, he lit a *flambeau* that heightened this fantastic picture, and made our memories revert to poems and scenes of *Manfred* and *Faust*; for was it not a natural Brocken

* Concluded from page 734.

with all the rugged and eccentric cliffs and peaks? and very little imagination was required to people it with the characters with which it was associated.

Our wonder was not yet satisfied, for from this height a green light or Roman candle was fired, which described an arc over our heads like a shooting star in the firmament, and falling through space showed that the darkness below represented a depth of 200 or 300 feet more. The assistant guide having wended his way to the bottom of this abyss and lit a kind of beacon light, we now had details of the extremes of the area. So well was this arranged that a stage manager could well get some useful hints, for no situation in any dramatic representation that we have witnessed would at all approach this for surprises and enchantment. A hearty round of applause greeted our guide on his returning down the rock, which he descended with the agility and surefootedness of a chamois.*

The end had not yet come, for we continued our journey along the remainder of the seventeen galleries which had such typical names as the Swallow, Grand Central, Precipice, Adventurers, Lost, Hope, Hogard, Imprudent, Incomparable, Cascade, Styx, Capitole, Broeche, Trophy, &c., and as we wandered through these endless pathways it seemed as if we had been weeks instead of hours in them; each mind having full opportunity of giving scope to its own imagining and conjuring into reality every nightmare or fancy of the brain. A new light was, however, dawning upon us, for we were about to leave the pitch darkness of the stoney cavern, with all its weirdness and secrets of the past, and like the tempest-tossed mariners coming home, felt hope strongly ascendant.

This light was to be the acme of our pleasure; but the guide, well knowing the power of his surprise, and how our sensitive nerves and eyesight, already strung and strained to the highest pitch, could not withstand the sudden transition to daylight—for the burst of sunlight upon us would have made us mad—by slow and easy stages, always changeful and exciting, schooled our senses for the contrast. By careful grouping the party were ranged at the edge of a rock, the protecting ledge preventing a fall of sixty feet or so into an abyss. The guide taking one of the lamps, we saw him gradually descend a pathway in the rock until his diminished figure reached the edge of a subterranean lake. Here he entered a boat, and there was little water to be seen, save where the lamp's reflected light revealed it, but the splashing of the oars in the profound stillness told us that it was vast and far-reaching. While thus standing, out of the darkness came the sounds of sweet melody, resounding from rock to rock, echoing and re-echoing, sometimes near, and then far off, and our guide's song in good baritone was completed on his way back to us. The greatest enchantment now awaited us, for it was our turn to follow the winding path the guide had just trod—lamp bearers and visitors, a goodly throng—down to the water's edge. Good accommodation was here found for all in three flat-bottomed boats, holding twenty-five persons each, the lamp bearers occupying a boat by themselves, and their lamps lighting up the roof and the walls of the water cave. In an instant the lights were extinguished, and we realised what the darkness of the cave was. The impression was supreme, for in this cavern on the dark lake, with no apparent outlet, we were helpless and hopeless. A few seconds and the whole surroundings are changed, for the boats have glided a few yards past a projection, and the cave is lit up by the silver rays of the moon. But where do they come from? It is moonlight apparently, and that of a harvest moon, but as it is only three o'clock and autumn—what is the meaning? A little thought and we understand it is the reflection of the rays of daylight again and again broken up by the water and sides of the cave. It was a light that spoke of hope and love once more, and brought joy to our hearts.

One silent corner there is yet to pass, and then we are face to face with a vision seen never on *terra firma*, and rarely conjured up in dreams; in fact, the finest transformation scene ever set up is but a poor attempt to imitate what nature here supplied. It was fairyland—I had almost said paradise—for description fails to convey the idea, or tell why tears ran down from every eye that saw this magic splendour and the bright mingling of colours, prismatic hues, translucent and glorious light from sky, foliage, rustic bridge, and mountain, reflected in the water of the lake beneath, all seen through the distant opening of the cave. It was a sight that would arouse the dulllest mind to an appreciation of the beautiful, and would soften the hardest heart. This sight was no doubt tenfold more effective after so long an absence from daylight than it would have been if witnessed from the same spot directly after being brought in from the water entrance.

The wonderful reverberations of the report of a small cannon fired in the mouth of the cave, echoing and re-echoing again and again, closed this wonderfully entertaining journey, and it was now only left for us to pay the fee (five francs each person), and give the guide some practical proof of our pleasure and thanks prior to returning to the waggonette. This we found outside a village hotel, and wishing to see what had been already done in the way of photographs, which it was understood were on sale here, we looked through the collection, and were disappointed to find no real pictures among them as photographs, for although so many beautiful, natural pictures had just been witnessed, none had been published

* This hall is one of those where the flash lights and magnesium would have to be used to get an idea on the extra sensitive plates of the vastness of the natural exactions.

worth bringing away as *souvenirs*. I should advise the photographer to first go through the halls and galleries and witness the effects, making mental notes of the opportunities of photographing, and one or two trial exposures, and then on a second or third journey through the caves secure negatives of those subjects most fancied, when the previous experience of exposure, &c., could be brought to bear on the result. A treat is in store for all who visit the Grotto of Hans.

EDWARDS'S ISOCHROMATIC PLATE COMPETITION.

PRIZE WINNERS.

Class A. Landscape.—1st prize, *Long Focus*, Francis William Edwards, 87, Bellenden-road, Peckham-rye, S.E. 2nd, *Tulipe Noir*, Frederic d'Arcis, 6, Brent-villas, Hendon, N.W. 3rd, *Carolus*, Charles Ariel Brightman, 61, Lyndale, Redland-road, Bristol. 4th, *The Rose Queen*, Albert Joseph Clark, 157A, Graham-road, Dalston, N.E.

Class B. Instantaneous.—1st, *Aurora Borealis*, Lyd. Sawyer, New-castle-on-Tyne. 2nd, *Paulatlon*, Ralph W. Robinson, Redhill. 3rd, *Infant*, H. Dudley Arnott, Gorleston, Great Yarmouth. 4th, *Home*, Alfred Price, 26, King-street, Great Yarmouth.

Class C. Interiora.—1st, *Autumnus*, Edward Brightman, Lyndale, Redland-road, Bristol. 2nd, *Dum Spiro Spero*, Wm. Ellis, 25, Clapton-square, London, N.E. 3rd, *Floreat Cantabrigia*, Rev. F. C. Lambert, Ruberdoms, Cambridge.

Our Editorial Table.

ILFORD BROMIDE PAPER.

Britannia Works Company, Ilford.

WHEN first trying this paper, we made several prints which were perfect in all save one respect—there was a certain marking visible in every print, and which was not to be seen in some others made on paper of another maker. Puzzled at first to account for this, we examined the negative by holding it up against the light, observing nothing therein to cause such mark. We then examined it more critically against a backing of opal glass, when we found that the Ilford bromide paper had been quicker at detecting and giving effect to a barely visible detail in the negative than we were. Here at once we perceived a great virtue in this paper, viz., that of recording such delicate gradations of tone in a negative as were unappreciated by the eye. The sensitiveness is great, the tone is excellent, and the gradation all that the most fastidious could possibly desire.

PATENTS COMPLETED.

IMPROVEMENTS IN THE METHOD OF MOUNTING PHOTOGRAPHIC AND OTHER LENSES.

No. 12,343. DAVID WILLIAM NOAKES, 9, Billingsgate-street, Greenwich, Kent.—October 19, 1889.

My invention relates more especially to double or combination lenses, where the stops or diaphragms or exposure shutters are introduced between the lenses. Hitherto most lenses fitted with a series of stops or diaphragms have been so mounted that the stops have been introduced between the lenses by means of a slot cut in the lens mount, with the consequent tendency of the light to leak in to the interior of the lens. Again, when exposure shutters are used, especially those working between the lenses and without means of adjustment, so as to reduce or enlarge the extent of their opening, there has been difficulty in limiting the aperture of the lens to the intensity ratio required. To obviate these and other defects, I mount one or more of the lenses of the combination (preferably the front lens or lenses) in a distinct and separate tube. This is made to fit the outer or jacket tube in such a manner as to withdraw easily. A stop of the largest aperture intended to be used is fixed at C (which in the drawing represents the inner end of the short tube in which the front lens is fixed). Other stops of varying intensity ratios are easily introduced by withdrawing the tube and inserting a stop of the character and shape desired.

IMPROVEMENTS IN AND CONNECTED WITH PHOTOGRAPHIC CAMERAS.

No. 15,068. THOMAS PERCY GRAHAM, St. Mary's, Belfast.—October 19, 1889.

The object of my present invention is to improve the appearance of the well-known photographic camera, and to render it an object of interest to children sitters, obviating the necessity of fixing their attention upon anything outside the camera itself.

For this purpose, I place in front of the camera an ornamental structure of a pleasing design, and in which a hole is cut for receiving the lens tube. Above the hole is an arrangement very similar to the ordinary cuckoo clock, although I do not confine myself to any particular bird, beast, or figure. Sound is emitted by such figure by a bellows forming part of the arrangement. In front of the lens are doors for exposing the plate. These doors or shutters, together with the speaking figure, are worked automatically by any approved method, but I prefer the pneumatic ball and tube, a method of rapid exposure well known to photographers. The movement may also be given to the several parts by an electric current, or by hand.

The action is as follows:—The sitter is placed before the camera in the usual way and told to look full at the camera face. The design of this face is sufficient to create an interest, and to produce a natural expression of countenance so desirable in a portrait. While the attention of the sitter is so fixed, everything being otherwise prepared, the pneumatic ball, electric button, or hand connexion is actuated, simultaneously releasing the speaking figure and opening the lens shutters. The figure appears. The bellows produce the necessary sound. The shutters open and expose the plate, and the picture is taken.

[The invention here described is nearly allied to that long employed for a similar purpose in America, which latter is in the form of a handsome ornamental case with an aperture in front, at which, by means of clockwork, various sensational pictures appear in succession, but differs from it in this respect that the American one does not form "part and parcel" of the camera, but is mounted independently on a separate and adjustable stand.—Ed.]

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 59. OTTOMAR ANSCHÜTZ, Lissa, Posen, Prussia.—October 19, 1889.

My invention relates to photographic cameras principally designed for taking instantaneous photographs, and its object is to provide means—firstly, for producing photographs of the said kind which are clearer than those heretofore made; secondly, for altering the time of exposure; and, thirdly, for facilitating the adjustment of the lens to the focus corresponding to the distance of the object to be photographed.

For the first purpose I provide the camera with a shutter, having a slit, and so located within the camera as to move with the slitted portion along the rear wall of the camera, i.e. the wall containing the exposure opening. The shutter may be carried out in different manners. It may, for instance, consist in two pieces of antransparent cloth, so connected together as to leave the required slit between them, the outer edge of one piece being fastened to a winding barrel, having combined with it a catching and disengaging mechanism, while the outer edge of the other piece is attached to indiarubber cords. Or the shutter is constituted by a light box open at two opposite sides, and arranged in the camera so as to be directed with the said sides respectively towards the lens and towards the exposure opening. This box is connected to the camera by guiding devices adapted to conduct the same with its slit across the exposure opening, and it is provided with a catching and disengaging contrivance and springs or indiarubber cords as in the first arrangement.

By means of a shutter which moves with its slitted part close to the sensitive surface, as described, the said surface is exposed in successive strips to the full action of the concentrated rays of light forming the picture, while dispersed rays are excluded.

For altering the time of exposure the shutter is provided with an adjusting device, whereby the width of the slit can be varied. In the shutter of the first arrangement the edges of the pieces of cloth forming the slit are fitted with narrow metal mountings, one of which constitutes a guide for a resilient sliding pall, arranged to engage with ratchet teeth formed on the said guide. From the top of this mounting a cord is passed through eyes at the ends of the other mounting, then through an eye at the bottom of the first mounting, and finally to the pall, to which it is fastened. The cord thus forms an adjustable connexion between the two parts of the shutter, the distance between the said

parts being reduced when the cord is drawn upon, by means of the pall, whereas, when the cord is slackened by disengaging the pall and shifting it backward, the aforesaid springs or indiarubber cords cause the said distance to be increased. The same contrivance may be applied to the shutter of the second arrangement, provided only the walls forming the slit or the ends of the said walls be made moveable in respect to each other.

For the purpose of facilitating the adjustment of the lens, the easing thereof is provided at one end with a screw thread, with which it is screwed into a ring fixed to the camera, so that the lens may be focussed by screwing the casing more or less in or out. Besides this, the casing is fitted with a pointer, and on the ring marks are made, which show the position the pointer must have when the picture surface is in the focus corresponding to the distance indicated by any of the marks.

[Herr Anschütz when taking his patent was doubtless not aware that shutters, with a slot, working immediately in front of the plate have long been known in this country.—Ed.]

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
November 19	North London	Myddelton Hall, Upper-st., Islington

" 21	London and Provincial	Masons Hall Tavern, Basinghall-st.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

NOVEMBER 13.—Mr. J. Glaisher, F.R.S., in the chair.

A paper was read by Captain W. DE W. ABNEY on *The Density of a Negative after Intensification*, in the course of which he remarked that whilst the question of intensification had been dealt with by many writers, it appeared to have only been considered from a qualitative point of view. He proposed to treat it in a quantitative manner, examining the intensity added to the various gradations of the negative image from the faintest up to the strongest. Thus examined, he found that the relations between the several gradations did not bear the same proportion to each other after intensification as before. The intensifying formula that he had used in his experiments was that in which the negative was first treated with a bath of bichloride of mercury and bromide of potassium, followed, after washing, by one of nitrate of silver and cyanide of potassium. He found that in the result the gradation at the end of the scale was not proportionally rendered, and that, in fact, about one-third of the range of gradation was gone.

Mr. W. E. DEBENHAM inquired what would be the result with other modes of intensification. He remembered to have considered in the collodion times, when silver and pyro intensification was in general use, that there was some distinctive difference between the result when this method was employed from that obtained with a mercury intensifying process. With the latter there appeared to be a more complete bringing up of the fainter shades, whilst with the pyro and silver method these shades seemed not to take the intensifying proportionally to the action upon the more exposed portions. Thus pyro and silver would appear to be advantageous for a somewhat over exposed negative, whilst it would accentuate the failings of an under exposed one, for which the mercury method would be more suitable. He would also suggest that Captain Abney, with his experience of measuring density, should repeat his experiment on two plates, intensifying one by the method mentioned in the paper, and the other with iodide of mercury, followed by solution of Schlippe's salt, and report the result at a future meeting.

Captain ABNEY agreed with Mr. Debenham as to the characteristics of silver with pyro intensification as compared with that by means of a mercury solution. As to the experiment suggested with iodide of mercury and Schlippe's salt, he would willingly undertake and report upon it.

Mr. CHAPMAN JONES inquired whether the formula stated to be used by Captain Abney did not first intensify and afterwards reduce the intensity of the negative; and, if so, did not that circumstance account for the want of range of gradation in the places of greatest deposit?

Captain ABNEY replied that he stopped the process before reduction set in.

Mr. JONES said that it was a question whether it was possible to proceed to full density in one part of the scale before the commencement of a reducing action in other portions.

Mr. W. BEDFORD inquired whether Captain Abney had tried the converse of intensification, namely, reducing intensity, and, if so, whether he had found the same curve of altered relation to occur.

Captain ABNEY had not experimented in that direction.

Mr. FRIESE GREENE wished to know whether Captain Abney had made experiments with emulsions prepared respectively with hard and soft gelatines. He believed that the results would be different in the two cases.

Captain ABNEY had used commercial plates and some of his own preparation, the latter being made with soft gelatine. He had not observed or expected to find difference of result from that source.

The PRESIDENT then distributed the medals that had been awarded at the Exhibition, and speaking of the Exhibition itself, then about to close, expressed his satisfaction with the progress in science, in art, and in photographic results

that had been displayed. The only thing that he did not like was the preponderance of great white margins to the pictures; with that exception, he had been exceedingly well pleased. The Exhibition had been visited by 12,600 persons, and had been financially, as well as in other ways, a success.

It was announced that at the next ordinary meeting, on December 11, Mr. W. E. Debenham would read a paper on *Estimating the Efficiency of Plate Backings*; and Mr. Whipple, of Kew Observatory, one on *The Application of Photography to Meteorology*.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 7.—Mr. J. J. Briginshaw in the chair.

A circular which had been received by the Secretary was laid before the meeting. It contained proposals for the formation of a new photographic society.

The meeting unanimously directed the Secretary to reply that the Society would take no action in the matter at present.

Mr. A. COWAN brought some transparencies which had been developed with different samples and quantities of sulphite of soda, and without that addition. One of the plates, which by several members was considered to be as good as any of the series, was found to have been developed with the old formula of pyro, two grains; bromide, two grains; and ammonia, four minims, to the ounce of solution. This plate had also not been treated with alum or any clearing solution. The plates were of a special make for lantern work, and slower than the ordinary bromide negative emulsions. One, as a curiosity, had been developed with eikonogen without the addition of any other substance to the solution; the image was apparently all out, but thin. The eikonogen was of the new variety, in comparatively large white crystals; a sample of it was shown, and it was stated to keep much better than the originally issued brown, powdery compound. The use of plain eikonogen without addition was not recommended, as in time the plate would develop all over.

A question from the box was read:—"In using the back combination of a rapid rectilinear lens, is the sharpest image procurable on the screen the best for photographic purposes? if not, what is the correction necessary?"

Mr. W. E. DEBENHAM said it was conceivable that a rectilinear doublet might be constructed, one of the elements of which was under and the other over-corrected, and in that case there would be a necessity for making an allowance when either was used separately. He was not aware that any of the commercial lenses were made in this way. Certainly each part of the combination was generally achromatised in itself, and could be used without any alteration of focus becoming necessary.

Mr. A. HADDON noted that when he had at times endeavoured to develop an image with pyro and carbonate of soda or potash and failed to get an image, and had then washed off the mixture and applied a fresh developer composed of pyro and ammonia, he had got green fog; whereas commencing with the pyro and ammonia the plate would remain clear. He attributed the green fog to a little of the originally used alkali remaining in the film.

Mr. F. W. COX had met with a similar result.

Mr. HADDON suggested that some samples of sulphite of soda might contain a quantity of carbonate of soda, and so be the cause of green fog.

Mr. G. W. ATKINS asked for a formula for varnish for transparencies that could be used cold.

Mr. COWAN suggested gum sandarac in ether.

Mr. F. A. BRIDGE said dammar in benzole.

Mr. DEBENHAM would use mastic dissolved in benzole or turpentine—the latter if time in drying was not important. A weak solution would suffice for transparencies, say one part of gum in twenty of solvent.

The subject of *Eikonogen as a Developer* was announced for discussion on the 21st instant, and on the 25th Mr. P. Everett will discourse upon *The Action of Ferripyrocatechol of Potassium upon Developed Plates*.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

On the 8th instant the Exhibition at Pall Mall was, by kind permission of the Photographic Society, open during the evening for the annual benefit of the Photographers' Benevolent Association. A lantern display from slides lent by Messrs. Combrano, England, Freshwater, Hastings, Pilkington, Smith, and Wright, concluded a very satisfactory evening's entertainment.

CAMERA CLUB.

OCTOBER 31.—The subject for discussion was the new developer, *Eikonogen*. Papers were read by Messrs. H. M. Elder, M.A., and Lionel Clark. Mr. A. Strohl occupied the chair.

Previous to the lecture Mr. J. H. Williams handed round a lantern slide on one of the Alpha plates introduced by the Ilford Company. With these plates variety in colour is obtainable by toning as with the Alpha paper.

Mr. G. DAVISON also showed one or two pieces of the Eastman Company's new thin celluloid film for the roller slide, which excited much interest.

In treating of the subject of the evening, Mr. ELDER confined his remarks to dealing with the chemical constitution and characteristics of the substance known to photographers as eikonogen. Mr. Lionel Clark's paper was devoted to a description of practical tests made for the purpose of comparing the merits of eikonogen with those of pyro, and it was illustrated by a set of negatives showing the results of these sensitometer tests. Both the lecturers appeared to agree that eikonogen gave density with difficulty, and had a tendency, under some circumstances, to eat away the film.

Only eight or nine of those present had tried the developer.

Mr. CHAPMAN JONES had not found that it rendered the film of negatives tender.

Mr. A. COWAN exhibited some good negatives to show the results obtainable, and some negatives and prints lent by Mr. H. M. Hastings, which illustrated the use of the developer for exceedingly short exposures. He also exhibited a sample of eikonogen in white crystals, and made some interesting remarks as to formulae and practice.

Remarks were also made by Messrs. Noel-Cox, Grimshaw, and Charters White, the opinions as to the qualities of the developer being very divergent.

The subject on Thursday, November 14, will be *Films*, when Major J. F. Nott will read a paper.

NOVEMBER 7.—Mr. A. PRINGLE gave an address entitled *One Hundred and Thirty Exposures*. Mr. Francis Cobb occupied the chair. There was a full meeting.

Mr. Pringle's lecture dealt with the advantages accruing from the use of orthochromatic plates in landscape work. To illustrate his points, Mr. Pringle had prepared a large number of prints and lantern slides; these were handed round and shown in the lantern. In most cases the lecturer had taken three negatives of each subject—one upon an ordinary plate, one upon an isochromatic plate, and one upon a plate dyed by himself; from these negatives transparencies had been prepared and were now shown together on the screen. The conclusion arrived at by Mr. Pringle was that some slight advantage was gained by the use of dyed plates without a screen in landscape work.

After the address some conversation took place; in this Messrs. B. J. Edwards, Webber, Birt, Aeres, Davison, and others took part.

The subject for Thursday, November 21, is *The Progress of Hydroquinone*, when a paper will be read by Mr. A. Maskell.

WEST LONDON PHOTOGRAPHIC SOCIETY.

NOVEMBER 8.—The President (Charles Bilton, B.A.) in the chair.

Mr. LYONEL CLARK described his new method of toning with salts of platinum, and gave a practical demonstration of the process, and numerous questions were asked by members.

Mr. BLACKMORE thought everybody must admit that Mr. Clark had brought before them a very beautiful process; the only doubtful point appeared to be the question of permanency. He hoped Mr. Clark would continue his experiments until he arrived at a result which might compete with any known process in that respect. He would ask: Would the result of over-printing and over-toning be to effect a more complete interchange of molecules—a point in favour of increased permanency?

Mr. E. W. FOXLEE inquired whether Mr. Clark could give an idea of the composition of the platinum-toned image, i.e., the proportion of platinum to silver.

Mr. CLARK, in reply, said that no doubt the over-printing and toning referred to by Mr. Blackmore would conduce to the permanency of the result, but the effect of considerable over-toning was to reduce the intensity of the print, as was the case with gold toning. To arrive at the relative proportions of platinum and silver in the image would necessitate having recourse to an abstruse analysis. There was, however, some silver present, for a print on being treated with an oxidising agent would lose intensity. No greater degree of over-printing was required than when toning with gold, except when using matt surface paper. One point must be observed—the bath must be always slightly acid, if at all alkaline the toning would be extremely slow. A bath smelling faintly of ammonia would have very little toning action.

In answer to the question, Has a landscape lens any advantage over the back combination of a rectilinear? Mr. FOXLEE thought that the old form of landscape lens would give a better result, inasmuch as it could be used with a larger aperture, but the back lens of the rectilinear would cover a larger field.

Mr. WHITING thought Dallmeyer's new landscape lens was a distinct improvement.

Mr. FOXLEE did not quite agree. The chief advantage of the single lens lay in the fact of its having but two reflecting surfaces, but the new lens had four—it had, however, rectilinear properties, which was a gain.

Mr. CLARK did not favour the employment of the back combination, inasmuch as the angle given was generally too small for pictorial effect; further, the position of the stop was not correct, and if an adapter had to be used it would save time to employ a proper lens.

The next meeting, which takes place on November 22, will be a lantern night. Members are requested to bring slides.

LEWES PHOTOGRAPHIC SOCIETY.

NOVEMBER 7.—Mr. G. J. Wightman in the chair.

The evening was devoted to a discussion on *Developers*, which was opened by Mr. P. MORRIS, who described in detail the methods of development by ferrous oxalate, alkaline pyro, and quinol, and concluded by saying he thought pyro-developed negatives gave the best prints, but that quinol was preferable for lantern slides and transparencies. In the discussion the general opinion seemed to be that the merits of quinol had been rather over-rated, and that photographers were gradually coming back to pyro.

The HON. SECRETARY spoke in favour of quinol for negatives, and thought its capabilities of giving gradation had been very much lessened by trying to hurry its action by the use of the caustic alkalis in combination with it. He preferred the fixed alkalis, and used carbonate of potash.

Mr. G. J. WIGHTMAN passed round negatives of the same subject developed by pyro, without a preservative, and quinol, also platinum prints from same; and the print from the quinol-developed negative was thought to be the best.

Mr. A. R. Dresser will read a paper on *Detective Cameras* at the next meeting to be held on December 3.

COVENTRY AND MIDLAND PHOTOGRAPHIC SOCIETY.

NOVEMBER 6.—Annual meeting.—Mr. Councillor Andrews in the chair, and a fair number of members present.

The consideration of the annual report was postponed until next meeting.

The following officers were elected for the ensuing year:—*President*: Mr. Councillor Andrews.—*Vice-Presidents*: Messrs. H. Stumey, G. Winstanley,

F. W. Hardy, and H. W. Jones, F.C.S.—*Council*: Messrs. A. B. Clarke, C. H. Waters, J. Mountfort, and W. R. Goate.—*Treasurer*: Mr. W. L. J. Orton.—*Secretaries*: Mr. F. W. Dew, The City Studio, Coventry, and Mr. F. J. Harker, 40 Smithford-street, Coventry.

Several schemes for increasing the utility and membership of the Society were mooted and referred to the Council for them to consider and report thereon at the next meeting.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 6.—Dr. Anderson (Vice-President) in the chair.

The proposed exhibition it was agreed should be deferred until the autumn of next year.

Mr. GEORGE MACKIE, A.Ph.S., then read a paper on *Microscopic Objects, and How to Photograph Them*, which was illustrated by lantern slides—photographic and hand drawn. Thereafter a diatom was photographed, being magnified to three inches in diameter.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 7.—Mr. W. D. Valentine in the chair.

Seven new members were elected.

The following were declared the prize winners in the bromide print competition:—Equal firsts—Mr. D. Ireland and "Ignotus"; second, Mr. W. Salmond; and third, Mr. V. C. Baird.

The method adopted in this competition was as follows:—Packets containing six marked pieces of Mawson & Swan's bromide paper were issued to competitors at the previous meeting; the paper could be cut down to suit the competitor's negatives, but the distinguishing mark might not be obliterated, and only three prints had to be sent in.

In a discussion on eikonogen several members gave their experiences, on the whole not very favourable to negative work, but that it promised well for transparencies used with soda carbonate as the alkali.

Specimens of Vèrel's printing-out opals, Friese Greene's opal carls, and Marion's lantern-slide cameras were exhibited.

Two silver prints on albumenised paper were found in the question box; the first had the following written on the back:—"What is the cause of blistering on this print? Blisters commenced in toning bath (bicarbonate of soda) and increased in fixing bath and washing."

The only solution propounded was that too much bicarbonate had been used. The second print:—"What is the cause of the white clouding over all this print? The negative shows no such clouds, and the print was all correct when it was washed after fixing."

The print must have come in contact with copper or brass while washing. This solution is probably correct, as the print was washed in a basin fitted with a brass plug and chain.

The meeting to be held on December 5 has been postponed till December 12.

PHOTOGRAPHISCHER VEREIN, HANOVER.

ORDINARY meeting, October 2, at Bruin's Hotel. There was a numerous attendance at this first meeting of the present winter season, and a great many points of interest were discussed.

Major VON HAMMARSTEIN, the President, after having welcomed the members present, called upon Herr KARL WUNDER to open the discussion, who accordingly gave the assembly a description of the Anschütz camera. The members listened to the opener's disquisition with great attention, and, by inspecting the fine negatives Herr Wunder had obtained by means of the camera in question, once more satisfied themselves of the practical value of Herr Anschütz's apparatus. The only drawbacks pointed out by the speaker were that the construction of the apparatus is not quite as strong as may be desired, and that some time is lost in adjusting the shutter according to the time of exposure; also, that in case of lengthened exposure care must be taken that no clouding takes place, due to the camera not shutting out the light thoroughly.

The arrangement of the shutter right in front of the plate occasioned a lively debate, and Dr. J. KNORRHAUKE notably endeavoured to demonstrate theoretically the distortion that "cannot fall" to result from the arrangement of the shutter, a position confuted by Herr KARL WUNDER, who called attention to the marvellous results obtained in practice—especially by Herr Anschütz himself—among which there were even enlargements on a considerable scale, free from any distortion.

Herr GEORG ALPERS, jun., then produced Tiessleke's monochromatic camera lamp, exhibited by Baron Brentano, and this, too, gave rise to some difference of opinion, as many members feared lest, in operating with very sensitive or with orthochromatic plates, clouding should occur.

Baron BRENTANO next proceeded to show a collection of very pretty landscapes, &c., taken by him last summer in Hungary.

The President then made a report of the present condition of the Hanover Professional School of Photography. Owing to the continued courtesy of the authorities, a fine lecture room is now exclusively placed at the disposal of the students, which is to be shut up after each lecture, which will enable both lecturers and students to leave in the room any articles they may require during the lectures, which they could not do before. A motion for the purchase of various instruments, &c., calculated to facilitate study was carried.

Lastly, the contents of two travelling portfolios of the German Photographic Association were examined, and excited so much admiration that a resolution was taken to order in future a travelling portfolio every month, and exhibit it for inspection on the day appointed for the meeting at Bruin's Hotel, and on the three succeeding days in the lecture room, so as to enable the general public to see it. The exhibition organized by Herr Georg Alpers, jun., was largely visited by the public, and generally approved of. Several artists especially expressed their sense of appreciation of many of the pictures exhibited.

Correspondence.

Correspondents should never write on both sides of the paper.

NOVEMBER MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—CAMERA FOR FOCUSING CORRECTLY.—GIFT OF 1500 FATTY INK PROOFS.—ENLARGED PORTRAITS OF THE TWO CELEBRATED PHYLLOXERA.—TABLE OF EXPOSURES FOR THE "PINHOLE" CAMERA.—TONING WITH PLATINUM.—M. ANDRA ON ICONOGENE.—SULPHITE OF SODA ADDED TO THE HYPOSULPHITE OF SODA BATH: ITS ADVANTAGES.—A SCIENTIFIC ACTINOMETER AND A PRINTING APPARATUS.—ICONOGENE DISTRIBUTED TO THE MEMBERS.—CLOSE OF THE PARIS EXHIBITION.

THE Photographic Society of France held their first meeting after their vacation on Friday evening last, the 8th instant, M. Davanne in the chair.

After the general business of reading letters and useful extracts from foreign photographic journals—in the which, by-the-by, the old BRITISH JOURNAL OF PHOTOGRAPHY always takes the lead—the presentation began. Several cameras were presented; one of them, an instantaneous hand camera, had a very ingenious appliance for focussing. It consisted in the adaptation of an instrument of a scissors form, which, opening more or less, advanced or drew back the tube of the lens, and so the focus is immediately changed. At the end of the blades of the scissors are two elevated points fixed at right angles. In a few words this is what the inventor says can be done:—

In taking an instantaneous view of a street, with persons promenading therein, one of those persons is selected by the operator, the scissors are opened, and the two points are made to coincide with the height of the person chosen; when the top point is on the head and the bottom on the feet, the trigger of the instantaneous shutter is pulled and the view is obtained.

To understand the working better, supposing the person chosen be at a distance of twenty yards, the points will be very little apart, but when this person has advanced to five yards from the camera, the mouth of the scissors will be full open, and the tube of the lens very much advanced.

This appears a good idea, and a progress on the system employed upon the kind of cameras called "detective," on which is a lever to adjust the focus according to the distance the object is from the camera, this distance to be appreciated by the operator at once, which is no easy thing to do without great practice. In fact, the sole value of this invention is to enable the operator to focus with certainty, and to do away with guessing work.

M. Balagny offered 1500 proofs of the prize negative in the Concours of 1889. These proofs were printed in fatty ink by his new process, which has not yet been made public. The President thanked M. Balagny in the name of the Society, and said that a print should be inserted in each "Bulletin," so that all members would receive a specimen.

M. Balagny was called upon by the President to renew his demonstration of his "Contretype Process." This he promised to do fully at a future meeting.

M. Donnadien presented a series of enlarged microscopic proofs of that destructive little animal, the phylloxera. Its history was thus given from the lava to the perfect insect; but what would have interested us more would have been to know how to destroy that plague, which has already ruined a great part of France.

M. Vidal, who has devoted so much of his time to photographic photography and calculations on the time of exposure, has compiled a new table of exposures to be used with "pinhole cameras," in which he has given the sizes of the pinhole, and for each of which he has calculated the time of exposure required for a fixed focal distance. No. 10 in the tables represents a fully lighted landscape; the actinometry of the light falls down to No. 1. It is intended to be used in conjunction with his actinometer, the principle of which is as follows:—A piece of sensitised albumenised paper is exposed in the shade for one minute; according to the intensity of colour obtained at the end of the minute, one or the other of the ten columns is chosen. Even without the actinometer these calculations may be useful. M. Vidal presented me with one, which I send on to THE BRITISH JOURNAL OF PHOTOGRAPHY.

M. Gastine presented a great number of proofs toned with platinum. This gentleman does all he can to introduce platinum toning in preference to gold. The proofs exhibited had certainly a marked superiority over the gold-toned ones.

The formula he recommends is as follows:—

A.	
Water	300
Sodium chloride	20
„ bi-tartrate	10

B.	
Water	100
Bi-chloride of platinum	10

Add 7 c.c. of B to A and tone. "It is advisable," said the author, "to eliminate the silver salts from the paper by one or two washings before toning. If bi-tartrate is not at hand, take five parts of tartaric acid and mix with four and a half parts of carbonate of soda."

M. Andra made a lengthy communication on Iconogène. He said he had been experimenting on it during the holidays, and was of the opinion that it is the best developer that ever came before the public. The tone it gives to the negatives makes them appear as the old bath plates developed by the iron solution.

The formula he succeeded the best with was composed as follows:—

A.	
Water	1000
Sulphite of soda	75
Iconogène	15 to 16

B.	
Water	1000
Carbonate of soda	150

The proportions to be employed are three parts of A to one of B.

M. Lany proposed the addition of soda-sulphite to the hyposulphite bath when the addition of alum to the latter was thought necessary. "The soda-sulphite," said he, "prevents the precipitate so disagreeable in the alum-hypo bath."

M. Dessendier gave a description of his photometer, which is based upon the following chemical reaction:—"If an equal volume of chlor and hydrogen be mixed together in the dark and kept there, the two gases will not combine, but if the mixture be exposed to light hydrochloric acid is produced proportionally to the light received." M. Dessendier entered into a long dissertation—impossible to get into the limited space I have at my disposal—and then exhibited his printing-press arrangement. It consists of ten iron boxes, side by side; a spring allows the cover of each box to rise; in the cover is a hole of the size of the negative to be printed; the negative is held to the inside of the cover by means of springs. Ten negatives can thus be placed. In each box is placed a few yards of the sensitive paper to be employed; the end is placed in a clamp attached to a cylinder, whose duty it is to draw on and wind up the paper exposed to light. To set to work, all the negatives are fixed to the interior of the lids, the paper is passed over a bed of black velvet and seized by the clamp, the lids are closed, and all is ready for work. Supposing albumenised paper be chosen, in the first part all the negatives must be regulated to print in the same time, so the operator chooses those which are thin and transparent, and places them so that the thinnest is in box No. 1 and the most dense is found in box No. 10. The machine is now set out to light. As soon as the positive under the thinnest negative is visible the action of light must be subdued to allow the others to come out; this is done by covering the lid with a blind made of fine woven silk—each lid has ten blinds. No. 2 box is now visited, and if it has obtained the same density as No. 1 a blind is pulled over the negative, and a second one over the first box, and soon until the last box be visited, when the positive from the most intense negative is fully exposed. The first box may be covered by six or more blinds. No. 3 may have two or more, and so on. All are now printed; a handle is turned, all the ten lids are lifted about the eighth of an inch, and the paper is immediately changed. Now here is the advantage: the operator only wants to look at one box; as soon as the proof is sufficiently printed all the others are the same—the handle is turned and all changed once more. Continual printing can thus be done without trouble and fatigue. Carbon proofs or gelatino-chloride paper proofs can be printed with ease and certainty, especially if the photometer of the invention be employed with the apparatus.

M. Schaeffner distributed a certain number of bottles containing pure iconogène manufactured by Dr. Andriessen, asking the members to experiment upon it.

A member called the attention of his colleagues to the fact that several chemists had their medicines placed in graduated bottles. These bottles will render great service, he said, to amateurs and others for measuring liquids.

At last the magnificent Paris Exhibition has closed its doors. In the British Photographic Section, though the exhibitors were few they were choice ones, and obtained deserved praise. The jury granted them rewards; receptions were offered them by the President of the Republic, and all was done to make their sojourn in Paris agreeable and pleasant.

196, Rue Legendre, Paris.

PROF. E. STEBBING.

GLASS POSITIVES.

To the Editor.

SIR,—I have read your article on the Alabastrine process. In years past I knew it well. I agree with you, very beautiful results were obtained. The reason the process was given up was—because they turned as yellow as a kite's claw. It is a fact that these pictures in this state, if exposed to the sun for a week or so, would lose this yellowness and regain their former whiteness. In this state they remained, not turning again. I never could account for it; no doubt many who used the process will bear me out in this statement. Can you throw any light on the subject? In the hands of an artist I have seen lovely things produced.

Your remarks as to positives are quite true, and I wonder they have never been taken up again. To take a really good positive was no mean task. If clear glass were used they could be looked at through the glass,

backing up with fine cotton velvet. I think there is a fine field for positives, if taken up by an artistic photographer. There is no doubt—as you say—they are as permanent as anything in photography.—I am, yours, &c.,

Cardiff, November 11, 1889.

H. D.

LENS MAKING.

To the Editor.

SIR,—On the 1st inst. there appeared a letter in the *English Mechanic* appealing to amateur opticians for some practical information in lens making, and on the 8th there is a letter in reply from another correspondent doubting the probability of such information being given, he having looked in vain for it for some fifteen years in the *English Mechanic*.

Now it seems to me that you, Sir, might, in the pages of our *BRITISH JOURNAL*, hasten to the rescue. Probably amongst the numerous readers of the *BRITISH JOURNAL* there may be some optical amateurs who could assist, and I have no doubt that any of your scientific and mechanical correspondents who took the subject up as a hobby would be only too pleased to communicate the results—successful or otherwise—to the pages from whence they first obtained their information.

I presume the appeal was made to amateurs in consequence of the apparently jealous way in which such matters are guarded by professional opticians; yet I really do not think the latter would suffer in the least—rather the contrary—were the information appealed for generally known. That standard formulae for calculating the achromatic and chemical corrections for lenses must be known to some of our clever amateur opticians there can be little doubt, and knowing how liberal advanced amateur photographers have always been with information for the benefit of their brethren in the black art, I think it possible that in the optics there may be found some one equally liberal with the particular facts in question.

If such articles or correspondence are likely to appear at all, there could be no better place for them than in your columns, at least so far as photographic lenses are concerned; and yet why not telescopic and microscopic as well?—they are used photographically every day; indeed, so far as photo-astronomical work is concerned, the wonder is where it will stop.

To many readers of THE *BRITISH JOURNAL OF PHOTOGRAPHY* I am sure the subject of lens making would be both interesting and instructive.—I am, yours, &c.,

Cosmos.

ELECTRIC-LIGHT LANTERNS.

To the Editor.

SIR,—With reference to my communication respecting electric-light lanterns, and Mr. Lewis Wright's remarks thereon, I should like to add the following:—In the hope of having, as he states, "no trouble or delay and very little expense" in availing myself of the light, I purchased one of the Edison-Swan incandescent lamps, and it was because it could not be used as issued with ordinary lanterns that I wrote about the matter. The lamp was made, as I understood, at the suggestion or to the design of Dr. Fleming by the Edison & Swan Company and is called the Focus Lamp. The stand supplied is a simple one, and answers very well if there is sufficient height between the base of lantern and centre of condenser to get the light in proper adjustment; but it was because the majority of lanterns have only a distance of about four and a half inches from the base or tray, while this is about five and a half inches, I had to scheme another way of doing it, and then had the gibbet arrangement made. Even with a six-inch condenser lantern there was not sufficient room, and so it can be understood that the general run of trade lanterns having four-inch condensers and paraffin lamps will not allow of its use as illustrated in last week's *JOURNAL*. Your readers and Mr. Lewis Wright will no doubt find when they come to try this incandescent lamp that the heat generated surprises them, as it did me, and that arrangements will have to be made for a different kind of lantern body of extra size and better ventilation if they wish to use it in comfort. Hence Dr. Fleming's design.—I am yours, &c.,

G. R. BAKER.

SNOW SCENES AND CLOUD EFFECTS.

To the Editor.

SIR,—Will you allow me to suggest two subjects for the *JOURNAL* which would, I think, be of much interest to your readers just now when ordinary photography is seldom possible—I refer to snow scenes and cloud effects?

As regards the first subject, viz., snow scenes, the amateur's usual difficulties may be summed up as follows:—

1. In the choice of a subject (say a fir-tree covered with a frost rime, which is a favourite one), should an endeavour be made to obtain a dark background, such as a distant hill?
2. Ought slow plates and a small aperture to be used, or *vice versa*?
3. In development should the action be stopped earlier than with an ordinary negative, to prevent obliteration of the snow effects?

4. Should the developer be weak or strong, or modified in any special way?

As regards *cloud effects*, the questions most frequently asked are:—

1. How near the sun should be the part selected?
2. Should slow plates and a small aperture be used?
3. Is there any special development needed?

And as most amateurs will desire to reproduce their cloud effects on film negatives (which are so much more convenient than glass), how is this done? Paper negatives almost invariably show the grain of the paper notwithstanding every care, and are very unsatisfactory.—I am, yours, &c.,

ACCIPITER.

Goring-on-Thames, November 7, 1889.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—Having read a letter over the signature "Bart Rous," I am led to ask whether the object of the Camera Club in their one-man exhibitions should be more to give instructions to young amateurs than to give pleasure to older ones in seeing the accumulated works of such a celebrated master as Mr. H. P. Robinson? I am less a disciple of the Robinson school than that of which Mr. Davison is the champion, but I think the thanks of photographers generally are well won by the Camera Club in exhibiting works that have had admirers many years, so that they may be more generally known than even now.

If, Sir, it is held the special duty of the Camera Club to instruct sucking amateurs, let a recommendation go to its Committee to buy and distribute a gross of the most popular shilling manual amongst them.

That in an exhibition of Mr. Rous's work faults many and merits few, compared with Mr. Robinson's work, might be found is the opinion of—
Yours, &c.,

A MEMBER OF THE CAMERA CLUB.

To the Editor.

SIR,—I am sorry Mr. Davies feels it so disagreeable to answer my questions, but he will excuse me when he considers that it is not a mere matter of *personality*, but a matter of fact we are discussing, as such "casual general observations" are liable to mislead in many directions. "External nature" is just the same as it always was, long before the "extremely modern school of landscape workers" existed, carefully studied, and can by the painter only be studied after nature, not after any engraving or painting, less by a photograph; as it is well known that photography never gives that which is called by the artist the *air tone*. But if this was not so, and photography could give the painter any information, this would not be "revolutionising" the landscape art, because the latter is that in painting what the lyric is in poetry; and to express this sentiment is the only problem of the art, not to give a minute description of a tree, or a cornfield, &c.

I am very sorry Mr. Davies does not comprehend that "colour, vegetable life," &c., have very much to do with landscape painting, and therefore stand in immediate relation to the question, more so, I should think, than any quotations from letters or art critics, &c., which bear no relation whatever to the points at issue.—I am, yours, &c.,

F. B.

EXHIBITION MATTERS.

To the Editor.

SIR,—An Old Medallist may congratulate himself that he is not the only one by very many who have journeyed up to town to see the "big show" in the hope of refreshing their artistic appetites and accumulating a little more knowledge, but who have been signally disappointed. Conspicuous by their absence, he says, are some of our best workers. Why? Have they received their prescribed share of favour, and now retire silently to digest the feed of a few years? or have they seen the red light, and have flown from the danger ahead? If so, for why? And to whom have we to look for a remedy?

"A dismal and cheap get-up" is the graphic description given by an old friend of the *tout ensemble* of the Exhibition. Common to the lowest degree are some of the frames that surround many of the pictures, and so out of keeping with the subject, that the careful study and manipulative skill that has been brought together to produce these pictures have, by the careless framing, been totally spoilt. But while committees do not appoint responsible persons to look after valuable pictures entrusted to their care, cheap and trashy frames will be the order.

Yet another and more serious grievance stares us in the face—I allude to the hanging of exhibits. If my memory serves me rightly, one of the conditions laid down in every prospectus is that the number of square feet required shall be stipulated at the time of applying for space. In compliance with this rule, and having paid the "necessary," is it too much to expect that the space required shall be all together? or are we to accept a few feet near the skylight, a few more feet on the ground, and the remainder wherever a vacancy occurs, while a chosen few can have

their pictures nicely hung and all together? In all cases, perhaps, it is not practicable, but in the majority it is. The duties of a Hanging Committee, we all know, are, under the most favourable circumstances, onerous. But when the spirit of fair play and a conscientious determination to do right be not with them, their duties then indeed are hard, and, with "An Old Medallist," it will be for us to ask for a new organization and a new Exhibition.—I am, yours, &c.,

WYRALL.

"AT HOME" PORTRAITURE.

To the Editor.

SIR,—May I be allowed to say in reference to your kind criticism on my Pall Mall exhibit that your assumption is quite correct—the portraits are absolutely free from retouching?

Though retouching is often necessary to the extent of taking out freckles and "sieh-like," which would otherwise make the face look unnaturally "spotty," to retouch characteristic lines out of a face is little short of criminal, especially in an old face. It is the old, old story of the use and abuse of a good thing.

The portraits in question were taken on an old sliding-box camera, guileless of swing back, in an ordinary bay-windowed room, with a six-inch R.R. at full aperture—about *f*-8. The chief difficulty was in getting short enough exposures to secure a natural, spontaneous expression, it being a very exceptional face that will stand a long exposure and give a natural, easy expression. Another difficulty is that when a characteristic pose is seen the lighting will perhaps not suit it, and to secure the best lighting and keep a happy pose is not easy where the light is so little under control. I sent the statement as to "no retouching" for insertion in the catalogue, but it failed to get an entry therein, to my great regret, it being a feature I wanted attention drawn to.—I am, yours, &c.,

FRED. H. EVANS.

158, Osbaldiston-road, Stamford-hill, N., November 12, 1889.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—In my last letter to you I stated that men fitted to enter business with any reasonable prospect of success would study well the *pros* and *cons* before they made the venture with their capital. Now I would like the writer who signs himself "An Amateur" to tell me on what ground he bases the right of claim to monopoly which he gives to the professional photographer.

Surely he knows little of the early history of photography; professionals have done little for it. They have done a great deal more for themselves.

I do not know whether Mr. Barnes was a professional photographer or a professional writer—perhaps he is both—but this I do know, that I agree with him that "I have yet to learn that it proves morality in a man to take the bread and butter out of the mouth of another *when he had no need for it himself*." And I may further add that I have yet to learn that it is wanting in morality for a man to take pay for honest labour to put bread and butter into the mouths of his family.

Professional photographers are not the needy, hungry creatures that "An Amateur" and Mr. Barnes would have us to believe they are; those with whom I am acquainted require no amateur's patronage or forbearance. They don't know the meaning of the cold word "charity," and I would say seriously to those who do, "Providence has not intended you for the vocation. Go, seek work of another kind, in which I hope you will be more fortunate."

"An Amateur" styles me "so-called amateur." On what ground does he do so? Certainly I am not a certified one by you, Mr. Editor.

In 1867 I bought my first outfit. I have been an ardent and diligent worker. I have received no pay for my work; the pleasure it gave me was enough. Of my work I have given freely away—an additional pleasure. Does an amateur give no copies away? I presume not.—I am, yours, &c.,

J. STONEY.

November 11, 1889.

To the Editor.

SIR,—Regarding the question as to "What is an amateur?" so far as being eligible for exhibiting purposes go, I should say that most cases must be decided on their own merits. In the first place, *all* the work, excepting coating the plates, and, perhaps, sensitising the paper, *must* be done by the exhibitor himself, and in the next place photography must be the hobby or recreation of the exhibitor, and not his business or profession. For instance, a man may be engaged in the City and does photography in his holidays, or out of business hours. That, I consider, is an amateur, whether he hands a print to a bazaar or even gets recouped his expenses for a copy.

A man of independent means, and who really goes in for work with the intention of getting paid for it, I should not rank as an amateur, whatever else he may be; but that is not my business. I fail to see—

selling a photograph, painting and selling a picture, and making a picture frame and getting paid for it, constitutes either a professional or a tradesman, and think, with you, that much of the difficulty arises from the lower grade of workers.—I am, yours, &c.,
H. R. W.

Exchange Column.

* * No charge is made for inserting *Exchanges of Apparatus in this column*; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange 12×10 bellows camera for a half-plate bellows camera with extra double dark slide.—Address, R. RAWLINSON, 1, Florence-street, Darwen.

Books on photography for amateurs, &c., in exchange for Wormald's *Key to Mechanics* or fireworks.—Address, J. R. RIGBY, Howick House, Burscough, Ormskirk.

I will exchange one interior and exterior flatted oil backgrounds, also balustrade and pedestal, for a 5×4 rapid rectilinear lens.—Address, H. MANISTRE, 26, Arlesford-road, Stockwell, S.W.

Will exchange Voigtlander's rapid portrait lens, two inches aperture and six and a half inches equivalent focus, specially constructed for taking children C.D.V. size, for Ross' portable symmetrical lens of six or eight-inch focus.—Address, TATE, Whitehouse, Belfast.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co., 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

Werner & Son, Dublin.—Four photographs of Right Hon. A. J. Balfour.

G. R.—The formula will be found among the "Answers" in this issue.

D. S. T.—Either lens will answer; we are best acquainted with the first on your list.

J. BARNES.—See answer to "E. C. Middleton." No alabastrine solution answers well with ferrotypes.

CHAS. GIBB.—By advertising in the *Photographic Times* and *Anthony's Bulletin*, both of them New York papers, your end will be served.

N. WELLS.—The only way to find out whether the photograph is copyright or not is to consult the register at Stationers' Hall. It is not necessary that a copyright picture be stamped as such.

C. RICHARD (St. Heliers).—The distance at which the universal sharpness would commence, with f-17 would be about forty feet. The portraits enclosed attest the suitability of the lens for such work.

C. B. says: "I recently intensified a number of negatives with bichloride of mercury and ammonia, and they have stained all over. What is the reason?"—Clearly the negatives were not thoroughly washed between the operations.

E. C. MIDDLETON.—A good formula for an alabastrine solution is the following: Saturate four drachms of hydrochloric acid with bichloride of mercury, then add four drachms of nitric acid, the same quantity of alcohol, and six ounces of water.

W. SALTER.—The transparent spots complained of arise from air bubbles sticking to the film during the development of the negative. The mottled appearance is due to the plate not being rocked sufficiently while the negative was being developed.

MORRISON LENCOSCOPE LENS.—Some reader has sent, doubtless at our own request, a defective lens for examination without any accompanying letter. Will he please communicate again, as we do not keep letters for reference when once answered.

R. BROWNING asks our opinion as to which is the best for treating the glass plate with prior to collodionising it in enamelling prints—wax or French chalk.—Either answers perfectly; some prefer one and some the other. The French chalk is the least trouble.

W. CROSS.—Lithographic rollers may be had from any printers' material dealer. The price of a twelve-inch roller is, we think, about 14s. There are two kinds, rough and smooth. The former is best suited for black ink, and the latter for the finer kinds of coloured ink.

B. JUN.—The marks on the prints forwarded are caused by the burnisher. The burnishing bar is evidently badly scratched. The remedy is obvious.

BORE.—1. Mount the pictures with starch paste made very thick, and using no more than is absolutely necessary. If you stick a piece of thin paper on the back of the mount, cockling will be avoided.—2. The Exhibition of the Photographic Society closed on Wednesday last.

A. C. wishes to know the best strength of bath for sensitising paper.—Very much depends upon the amount of chloride with which the paper is salted. Usually from forty-five to sixty grains of nitrate of silver to the ounce of water answers. Those from whom the paper was purchased will say the strength most suitable to employ.

REFLECTOR.—1, 2. Try a large-size reading glass of short focus.—3. Yes, if necessary. Perhaps you had better consult an oculist on the subject.—4. The reflector and arrangement you have is the same as that generally employed. Try the effect of a piece of white paper in place of the mirror. Possibly that may suit your requirements better.

F. BORLING asks us to give him instructions as to how to prepare sheet copper for engraving upon.—This is a long and tedious process for an amateur to undertake. It would take up too much space in this column to describe the method, and, moreover, it has no connexion with photography. Our correspondent will doubtless find it more profitable to purchase the plates ready for use.

INVENTOR.—The mere fact that the specification has been accepted at the Patent Office is no proof that the patent is a valid one. Scores of photographic patents are in existence which would not stand if they were contested in a court of law. Better consult one versed in Patent Law. It is always advisable to avoid litigation if possible. Litigating a patent is always a costly proceeding.

J. J. W. writes: "I have a diagram to copy, and the only lens I have that will take a picture the size required is an old single landscape lens, capable of covering a plate double the size. How can I avoid marginal distortion with it?"—If the lens is of sufficiently long focus to take a picture double the size of that to be produced, the distortion on the smaller plate will be so slight that it may be ignored in practice.

LEO says: "Four years ago I entrusted to the hands of a London artist a picture to enlarge on canvas and paint, for which I paid a good sum. The thing has now faded very much in the white parts. Can I claim back the money?"—Four years appears to be a short time for a picture to fade in, and we imagine that the producer would for his credit's sake do another if the matter is brought to his notice. The question can only be decided legally in a court of law.

A COUNTRY PHOTOGRAPHER complains that he recently sent a very valuable negative to a London firm for enlargement, and they say that it was found broken on its arrival. He asks who is responsible for the damage.—If the negative was properly packed and labelled "glass," the carriers are liable for the damage. Their attention should have been called to the injury at the time the package was delivered. They usually demur to recognising accidents after the lapse of two or three weeks.

NOVICE asks if the collodion sold for enamelling pictures will answer for negatives by the wet process if it were iodised, and, if so, how it should be iodised?—What is known as "enamel collodion" is not suitable for making negatives. As a rule, the solvents used are of too crude a character, and the pyroxyline not of the right character. Furthermore, this collodion often contains castor oil, a very undesirable substance in a negative collodion. If such a collodion were modified and iodised, it would quickly throw the silver bath out of order. Negative collodion must be made with the purest of solvents and with the proper kind of pyroxyline.

BIRMINGHAM.—A correspondent writing from this town who does not wish his name published, else would we give the letter in full, says, *apropos* of photographers keeping specimens of retouchers' and operators' work: "A few weeks ago I sent some beads to —, of Brighton, and I have sent to her several times asking her to return same, but can get no answer. One large bead is a very fine specimen, and I expect she is making use of same, as it has no name on mount. Being the only one I have of it, it is therefore of value to me."—It is really discreditable that any one should be guilty of such an act. We advise our correspondent to write to the Superintendent of Police, stating the circumstances and his suspicions, giving, of course, the full names and addresses. We ourselves have made a note of the name and shall be glad of the full address.

PHOTOGRAPHIC CLUB.—Subject for discussion on Wednesday—*Dark Room Appliances*, preceded by the adjourned annual meeting.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1542. VOL. XXXVI.—NOVEMBER 22, 1889.

PLATE-SHEATHS SUPERSEDED.

By a sheath we here mean a plate of blackened tin, or other thin metal, having its sides bent round so as to permit of a sensitive plate being inserted face out, the body of the tin plate forming such a backing as prevents light from passing through to any other sensitive plate which may be behind it, its lapped-over edges forming a protection to the face when a number are packed closely together. We have used these much during the past season in a hand camera, and have experienced considerable satisfaction in their employment. But since witnessing the extremely simple way which Messrs. Swinden & Earps have adopted of backing such plates with paper, and having subjected the same to a thorough practical trial, we have concluded that for small or hand camera plates the paper envelope possesses such advantages over the metallic sheaths that the latter may fairly be considered as superseded.

The backing of dry plates with opaque paper is so far from being a novelty, that special attention was directed to its employment for this purpose in connexion with an ingenious magazine camera, which was described in this JOURNAL many years ago, a camera in which a floor having a slot in it divided the space into two compartments, the plates stored in the upper compartment being passed, after exposure, through the slot into the lower division. This formed the subject of a patent which has long since expired. In this each plate was protected by a backing of opaque paper, although we then found that a backing of extremely thin zinc answered equally as well. Such zinc backing, with its edges turned on three sides to retain the plate into position, forms the sheath of the period.

What the gentlemen above-named have done is the giving us an exceedingly simple and effective way of applying the paper backing so as to retain all the advantages with none of the drawbacks which attend the employment of the metallic sheath, and we shall here describe it so plainly as to be very clearly understood.

What is wanted is to lay a plate, back down, upon a sheet of ruby or other opaque paper, a trifle larger than the plate in one direction, and then bend up the two opposite edges and cause them to overlap the sensitive surface to the extent, say, of an eighth of an inch, or even a little more. This, with a machine-like rapidity of action, forms the requirement, and we shall now explain how it has been met.

Procure a block of wood larger than the plate by an inch at each side, and of any thickness, as this is immaterial; one that we constructed is one and a half inches thick. Now cut into its upper surface a wide recess, capable of holding a plate in such a manner that when it is laid down flat in it the surface of such plate will be just a trifle lower than the level of the

two sides of the block. In the meantime, a packet of opaque paper must have been prepared for the backing. It is unnecessary that it be strongly sized or too thick, but it must be cut about half an inch larger in one direction of the plate, so as to allow of a quarter of an inch at each side for folding over the face of the plate. The operation of backing the plates is as follows:—Each of the two opposite edges of the paper having been slightly wetted to the extent of a quarter of an inch along the margin, the paper is laid down over the recess cut into the wooden block, and the plate is placed over the paper, sensitive side up. This, of course, leaves the superfluous marginal paper standing up above the level of the plate, and at the opposite sides, to the extent of about an eighth of an inch, and which, being wet, has merely to be bent down and pressed in contact with the gelatinous surface of the plate to ensure its adhesion. The means by which the paper edging is bent down and brought against the margin of the plate are simplicity itself. A flat strip of wood—or, more correctly, two, one at each side for simultaneous use—the length of the plate is provided, and this, in being slid over the face of the block and slightly on to the plate, bends down the paper border, and the slight pressure requisite ensures the contact of paper to glass. The edge of the wooden strip which performs this function has a small strip of rubber, which may be of the thickness of an eighth to a sixteenth of an inch; this ensures a more equal application of the pressure. By glue, pins, or otherwise, a slip is affixed along its outer edge below, to act as a check and prevent it from encroaching too far upon the plate when run in to bend down the paper.

Although it has taken some time to describe this apparatus, it is really very simple, and when everything is in readiness, plates can be backed at the rate of eight per minute; this, at any rate, is the record of the time we took when last using it. The special camera for which we have as yet utilised this system of backing is one of the hand class, originally made for use with sheaths, and in which the plates are dropped through a slit from a reservoir above to a compartment below. There being no patent restriction on its use, so far as we can learn, any one will be free to adopt this method of backing his plates with paper.

NEGLECTED PROCESSES.—METHODS OF PRODUCING NEGATIVES DIRECT FROM NEGATIVES.

From time to time various methods of making negatives direct from negatives at a single operation—that is, without the intervention of a transparency—have been published. The one which has, perhaps, received the most attention is the powder or dusting-on process, which was referred to a few

weeks back. But there are several others by which quite as good results may be obtained. Reproduced negatives, reversed or otherwise, are in constant requisition, and will be still further required as the different photo-mechanical processes become more general. It goes without saying, that in many respects, particularly that of sharpness, the reproduction—by whatever process—ought to be better when it is made from the original at a single operation, without the intervention of a transparency, leaving out of the question altogether the increased trouble involved in making the transparency.

One method of reproducing a negative direct is that by Major Russell's bromide process, or by the collodio-bromide process, for one is as good for the purpose as the other. The plate may be exposed either in the copying camera or by superposition. The image is then developed with an alkaline developer in the usual way, and washed, but not fixed. Of course, the image is a positive one—a transparency. The plate is then treated with nitric acid, which dissolves the positive image, and leaves a negative one behind in bromide of silver. After washing, to remove the acid, the plate is exposed to light, and then developed again as before. By this method exceedingly good reproductions can be made.

Excellent reproductions, either negatives from negatives, or transparencies from transparencies, may be obtained by taking advantage of what is known as the reversing action of light. This property was first discovered by Fox Talbot in the very early days of calotype. That the subject may be better understood, we shall here describe Talbot's discovery.

A sheet of paper was iodised, then sensitised with nitrate of silver, and dried. It was then exposed to light just long enough to cause the paper to blacken if the developer were applied at this stage. The paper was next treated with a solution of iodide of potassium and again dried. If the developer were applied now, the paper would still blacken; but if it were again exposed to light, the developer would have no action, so that the paper would remain white. Consequently, if the paper, after the second iodising, were exposed in the camera, a positive image, instead of a negative one, would result on development.

Many years after Talbot's discovery, Poitevin suggested utilising this principle for taking positives direct in the camera on wet collodion, and the late Mr. Window also suggested its employment in the production of enlargements.

In 1873, Mr. E. W. Foxlee read a paper before the South London Photographic Society on the subject, and showed some capital enlarged negatives made direct from the original ones. His method was as follows: A plate was coated with a lightly bromo-iodised collodion, and sensitised in the ordinary bath. It was then exposed to light, but only sufficiently long to produce fog if the developer were now applied. The plate was next washed and treated with a solution of iodide and bromide of potassium in water; it was then ready for exposure in the enlarging camera. After exposure, the iodiser was washed off and the plate again dipped in the silver bath. The image was then developed with the ordinary iron solution, when an excellent negative resulted, which was afterwards intensified, if required, and fixed in the ordinary manner.

In our volume for 1880, Mr. W. Brooks described a process for producing negatives direct from negatives which gave very good results. Mr. Brooks's method was this: A collodio-bromochloride emulsion plate is exposed behind a negative or in the copying camera. The picture is then developed with alkaline pyro, the result being, of course, a positive image. The plate

is then washed and immersed in an alcoholic solution of iodine until the image entirely disappears and the film looks the same as it did prior to development. After washing the plate, the developer is reapplied, when the original image again makes its appearance, but it quickly reverses and takes the negative form, the positive character quite disappearing as the development is continued.

About the time that Mr. Brooks published his method, Mr. Thomas Bolas described, before the Photographic Society of Great Britain, a very simple method of making reverse negatives, by the inverse action of light, with gelatine plate. The process is this: A gelatine-bromide plate is "sensitised" in a four per cent. solution of bichromate of potash, then rinsed with water, and dried. It is then exposed under a negative in a printing frame until a distinct image is apparent. The plate is now well washed to remove the bichromate, and it is then developed, either with the ferrous oxalate or the ordinary pyro developer, and fixed as usual. This method, beyond its simplicity, has the advantage of economy, inasmuch as almost any foggy plates, or those which may have been "light-struck" answer quite as well as good plates. It may here be mentioned that gelatine plates, without further treatment, will yield a negative image when exposed to a negative if they be very much over-exposed, but the reversing action is not so well under control as when the bichromate bath is employed.

It is somewhat difficult to say why some of the processes above referred to are not utilised in practice, particularly the last described, seeing that they are all capable of yielding good results. It may, perhaps, be that each of them entails a departure from the ordinary methods of working, and photographers do not care to leave their old paths.

AMATEUR DARK-ROOM APPLIANCES.

No. IV.

ANOTHER portable arrangement we have seen in use, and which has for a long time given every satisfaction to its owner and builder, consists of a framework put together precisely after the manner of a folding drawing-room screen, in three sections, and covered with opaque material. When folded so as to form three sides of a square, a top is fixed on by means of thumbscrews at the four corners; and this, assisted by the work table, attached in similar manner midway, braces the structure into a thoroughly rigid affair. The open side is provided with double curtains of suitable material, and the other arrangements are similar to those already described. For purely home use, this has the advantage over the previous arrangement of being more rapidly erected and taken down, and occupies even less space when stowed away; but it is not suited for travelling purposes.

We know many amateurs who, while enjoying the privilege of a special workroom, are compelled to devote it to a variety of purposes not altogether compatible with photography. How many amateur photographers are also amateur mechanics, and have to squeeze into, perhaps, one room, joiners' bench, lathe, circular saw, and what not, and use the room for developing as well? Matters are not so bad now, with gelatine plates; but in the old days of collodion, either wet or dry, such an arrangement would have been absolutely fatal to success, owing to the floating particles of dust of all kinds constantly pervading the atmosphere. Then, again, the nuisance of constantly having to shut out or let in daylight, according to the purpose in hand, condemns the practice on the score of convenience.

In such circumstances the most natural solution of the difficulty consists in partitioning off a portion of the room so as to form a permanent laboratory, borrowing its light from the outer apartment—an arrangement which is and has been in general use for very many years. But to most amateurs the idea of their constructing an inner room savours very much of getting in the builder's men for an indefinite period and enormous cost; but we have seen a perfectly comfortable and roomy dark room of this description which was built by its owner himself in a very few hours, and at the cost of as many shillings.

All that is required is the necessary quantity, according to size, of $2\frac{1}{2} \times 2$ inch "quartering," and a corresponding quantity of paperhangers' canvas. The framework of quartering is mortised together, and reaching right up to the ceiling, can be pushed into close contact by wedging from below, being finally fixed in position by fillets nailed to the floor. The uprights should be just so far apart as to suit the width of the canvas—usually about forty inches—which is next strained as tightly as possible and fixed with tacks an inch apart. Next, the canvas is thoroughly wetted, which causes it to shrink and become literally as "tight as a drum," and also prepares it for the next operation. This consists in pasting smoothly on to the canvas two or three layers of newspaper to form a "foundation" for any ornamental wall-paper, or for a coat of paint. This gives a wonderfully strong yet not bulky wall, and is, as already stated, both cheap and easily constructed. Of course, a door and frame have to be provided, but the door may be constructed in the same manner as the framework, and covered with canvas and paper.

For outdoor purposes, considering all things, it is perhaps better to employ wood or corrugated zinc, though at a pinch a similar construction to the above will answer the purpose. In this case, after attaching the canvas and newspaper to the framework, we should allow the whole to become thoroughly dry, after which we should cover it inside and out with "Willesden" paper, and finally with a coat of paint or tar. To our own knowledge, a house of this kind erected for another purpose some years ago is still perfectly weatherproof, having undergone no further repairs than an occasional "touch up" with paint.

From what we have now said, we think it may be fairly gathered that the amateur, no matter how confined his space, or how limited his means may be, need not condemn himself to a lifelong drudgery in the practice of his hobby, but by the exercise of a little judgment and ingenuity may provide himself with every necessary comfort at a very small cost.

We have many times pointed out the desirability of reproducing photographs of natural phenomena by some photographic process, instead of translating them into engravings, and so making pictures pretty but of questionable scientific value. But at the last meeting of the Royal Astronomical Society a failing in photographic technique in the representation of a variety of tint was unequivocally asserted; also a question arose as to the possibility of reproducing a very beautiful set of drawings of the milky way made by Dr. Boedlicker at the Earl of Rosse's observatory. Incidentally, we may refer to Captain Noble's suggestion that a negative of the drawings (which are dark on a white ground) should be reproduced rather than the drawings themselves, so as to present to the observer the actual appearance seen in the sky. This is a decidedly wise recommendation. Mr. Ranyard stated that with regard to the reproduction of such drawings by photography, Mr. Wesley and he had made several experiments in drawings of coronas and found that the photographic method was not suited for the reproduction of faint gradations of tint. The

Astronomer Royal said he had a few words with Lord Rosse on this subject, and he was inclined to think that nothing short of steel engravings would reproduce them satisfactorily.

Now here is a challenge to the profession. A set of beautiful drawings of astronomical objects have been produced by hand, and it is asserted that photography must be set aside in favour of hand work for the purpose of reproducing them. We should like to hear what some of our professional copyists would have to say on this subject, and our columns are open for any remarks they may have to offer.

APPROPOS of photography and astronomy, it may be noted that at the same meeting there was read a paper by Professor Pritchard on the *Determination of Stellar Parallax by means of Photography*. This paper represents a method of the highest ingenuity of design, originated entirely by Professor Pritchard, and has achieved results entirely photographic, which have been characterised by a well-known writer as being "certainly comparable with the most refined measures hitherto made, whether with the heliometer or micrometer, even if they do not, as is probable, surpass them in accuracy." This is high praise when it is so frequently stated that the drawback to photographs for star measurements is the difficulty in obtaining precise values. The method adopted is to take four plates per night at suitable intervals of time, the exposure having a maximum of five minutes. The negatives, which are made with the De la Rue reflector of thirteen inches aperture and ten feet focal length, are then measured with the De la Rue micrometer, the results having the value above described.

ALL photographers should have a knowledge of chemistry, though we are afraid it is not a common acquirement. It is a subject that cannot be "got up" by reading a book; experiment must accompany the study of the letterpress. For those who are just beginning to study, some help will be decidedly gained by the perusal and examination of a little work just published, in which the usual reactions are given in coloured table, instead of the customary tables of lists of elements and precipitates. These tables show, as nearly as possible, the precipitates in the colours they show, instead of in a series of words describing them; and in so far as the eye is educated rather than the memory, their employment should be a gain.

MOST of our readers have read accounts of the remarkable discovery in this country of a continuous lode of uranium ore, a discovery without a parallel, this metal having been hitherto most sparsely distributed wherever it was found. Its price in consequence was very high—about 20s. per pound. We allude to it here because of the continuous reference in the various newspaper paragraphs (originating, perhaps, in the endeavour to show the *raison d'être* for the inevitable "company") to its use in photography. Hitherto, it is stated, the metal has been used in the manufacture of a beautiful dichroic greenish glass, in producing a black upon porcelain, and in photography. We are not in a position to say what demand there may be for uranium in the two first-named directions, but we must observe that if it bears any analogy to that in photography, the profits from the sale per annum would not be likely to yield more than enough to buy a door-plate for the new company.

PHOTOGRAPHY, according to a foreign scientific journal, is about to be put to a new use in meteorological work. The determination of the temperature of the air at different heights is an important factor in meteorological investigations, and, as our readers may easily imagine, is a difficult problem to undertake, but the following outline of the new method suggests that something feasible has been designed. Herr Siegfels uses a thermometer which, by closure of an electric circuit when certain temperatures are reached, gives a light-signal. Small balloons, each containing such a thermometer, will be sent up at night, and the light will affect photographically a so-called photo-

theodolite, while the height then attained will be indicated in a mechanical way. It is hoped that this new method will enable more exact formulæ for decrease of temperature with height to be obtained.

LANTERN SLIDES ON GELATINE PLATES.

ASSUMING that the emulsion is to be employed at once—*i.e.*, within a day or two of washing—it may, after well draining to free it from as much water as possible, be at once melted up. If the directions previously given have been carefully followed, the bulk of emulsion will now be less than was originally intended, and the quantity must be made up with distilled water. Or it is sometimes an advantage to add a little alcohol in order to make it flow better on the glass, and also to help the rapid drying of the plates; but too large a proportion will cause a tendency to wavy markings in the film, from the mutually repellent nature of the gelatine and alcohol, as the former sets. Perhaps a maximum of six or seven per cent. of the total bulk will prove a safe proportion.

In this condition, especially when the addition of alcohol is made, the emulsion will keep at this time of year for several days without either decomposing or changing very materially in its photographic properties; but if it is impossible to use it up at once, or it is intended to keep it for some time, a little alcohol should be poured on to it after it has set in the bottle. This will protect it from atmospheric influence and preserve it for a considerable period; but when required for use, the alcohol must be poured off and the bottle well rinsed out with cold water before the emulsion is melted.

Considerable diversity of opinion has been expressed on the subject of the temperature the emulsion will bear at the time of coating, as well as the degree of heat that gives it the best flowing properties when coating. My own experience leads me to favour a tolerably high temperature, say about 120°, or even higher. This, so far as I have found, exercises no ill effect on the setting of the gelatine, even if it be melted up two or three times, and does away with the necessity for heating the plates before applying the emulsion, which is absolutely necessary when it is at a lower temperature, and, consequently, more readily brought down to its setting point on contact with the cold glass. At the temperature I have indicated, and the glass at the normal, not ice-cold, the emulsion will flow over the plate almost as easily as collodion, and after a little practice it will be possible to coat a large number of plates without losing a drop.

It will be necessary immediately before coating to filter the emulsion, however carefully that operation may have been performed previously, in order to remove any air bubbles or particles of foreign matter that may have been introduced during washing. The best material I have found for this purpose is fine cambric, made into the form of a bag, and provided with a support of some sort by which it may be suspended from the mouth of a beaker or jar. If two or three strands of fine thread be passed through the apex of the bag, so as to hang to the bottom of the receiving vessel, the emulsion will descend gently, and exhibit no tendency to form fresh bubbles, as is the case when it has to drop from a height.

Many contrivances were in vogue formerly for facilitating coating, in which that operation was carried on simultaneously with the filtration. The simplest of these, and probably the most easily attainable, consisted of the little Japanese teapots with inside strainer, obtainable for about a shilling. A small piece of cambric stretched over the outside of the strainer before placing it in position formed the filter, the emulsion was poured from the spout, and any excess returned to the strainer, so ensuring constant and perfect freedom from dust. The only objection to this arrangement lies in the shortness of the Japanese spout, which renders it difficult to coat large plates, but for lantern slides this trouble does not exist. Special coating pots, in which this defect was remedied, became articles of commerce, and such may, probably, still be picked up at some of the dealers.

The next point is the glass, and in this connexion the question arises of the advisability of coating the plates individually, or of preparing larger sizes and cutting them down to size after drying. I have no hesitation in deciding in favour of individual coating for many reasons. Cut plates are always more liable to frill where the tendency lurks than those in which the emulsion has got hold, as it

were, of the natural edge of the plate in setting. Besides, cutting in the dark room and through the layer of emulsion is never a satisfactory business, even when a good diamond is wielded by an experienced hand. The chances, too, of minute fragments of glass damaging the films is always present, and such defects are of more importance in a lantern plate than in larger sizes. But the amateur, even when he possesses a diamond, rarely has the necessary skill to use it to the best advantage, and rough edges are more than likely to be added to the other troubles. Nothing among the minor faults of lantern slides goes farther towards the production of an unsatisfactory result than rough edges and want of uniformity in size between the slide and cover-glass; the increased difficulty in mounting alone is sufficient to cause exasperation. Hence, I repeat, I strongly urge the use of plates cut to size before coating.

The only objections that can be urged against the practice are the longer time it takes and the chances of imperfect edges. With regard to the first, the little extra time occupied in coating is of no importance to the amateur, and is more than compensated by the superior result and the saving in the trouble of subsequent cutting; while after a little practice in coating there is no excuse whatever for badly covered plates.

Starting on the assumption that cut sizes, whether purchased or cut up at home, are to be used, the first operation is to clean the glass. I would, however, suggest as a preliminary, though not a necessary one, that the edges be slightly ground to take off the sharp edges, which will add greatly to the finish of the slide, and render the task of binding much easier. For this purpose a strip of rag-stone or slip for sharpening acythes answers well, or a small piece of smooth flagstone may be kept for the purpose. I procured such a piece at a stoneyard for a few pence, and used it for years for smoothing the edges of my glass for negatives; but latterly, for such small plates as lantern slides, I have adopted other means. If a grindstone be available, and an assistant to turn it, a number of plates may be treated in a very short time by holding each of the edges in succession at an acute angle with the side of the stone, pressing very lightly for a second or two. In my own practice, I apply the glass in the same manner to the side of an emery wheel revolving at a moderate speed in the lathe. Whatever the means adopted, the pressure must be very gentle, or pieces will be chipped out and the edges made worse than before. If the glass is cut accurately, no attempt need be made to smooth the *square* edge, but merely to slightly round off the corners, and a batch of plates so treated, if stacked together in a block, will present a wonderfully neat and uniform appearance.

After grinding the edges, the plates must be washed singly in warm water with a little washing soda, all dust and grease being carefully rubbed off with the fingers, or a piece of flannel or wash-leather, and, after rinsing under the tap, transferred to a vessel of hot water. When all are so treated, they are dried singly with a soft cotton cloth, the hot water greatly facilitating their rapid drying, and if the cloth be not allowed to get too damp no after polishing will be necessary. If upon breathing on the glass it should appear "smeary," a gentle polish with a perfectly dry linen or old silk handkerchief will complete the process. In all cases the polishing should be done some time before coating, in order to allow any electrical disturbance to subside, when adherent dust particles will be more readily removed. If a greater number of plates than are required at once be cleaned, the surplus ones should be dusted, packed together in contact, and stowed away in a dry place, wrapped in paper.

We now come to the coating, which to the inexperienced may, perhaps, at first present some little difficulty, and possibly some waste of emulsion, though this will soon disappear. What is chiefly required is a methodical system of working rather than any elaborate preparations. A cool room free from dust, a tolerably level table, and a sheet of plate glass, form the only requirements, beyond the coating vessel and another of hot water to keep the emulsion fluid. Place the light in front and at a suitable height to well illuminate the glass when coating, and on the table immediately in front of the operator should be a clean porcelain dish or similar receptacle to catch any emulsion that may escape over the edges of the glass in coating. This may be afterwards scraped up when set and returned to the stock.

Arrange the plate glass in a convenient position, and level it care-

fully and accurately by means of three small wedges applied at the points of a triangle, employing, of course, a spirit level as the guide. The levelling surface must be so placed that the direct light from the lamp or window does not fall on the films while setting, and it will be a further advantage if a light cover, a sheet of stout mill-board for instance, be placed a few inches above the slab for the double purpose of shutting off reflected light and preventing dust settling on the films.

The levelling slab need not be of large dimensions; an area of twelve inches square will comfortably hold half a dozen or even nine lantern plates, and by the time that number are coated, the first will be set and may be removed to the drying box. It is in every way desirable that the plates be placed in the drying box as soon as possible, as there is less risk of either light or dust getting to them there than when exposed in the open room; therefore, there is an advantage in using a small slab necessitating a frequent clearance.

Except with very perfect arrangements it is almost impossible to work sitting; it is much better to dispense with the chair, as it allows greater freedom in stepping from the coating place to the level, which can scarcely be within comfortable reach when sitting down, unless it be in front of the operator and underneath the lamp support. A shallow box with the end knocked out may be used to set the lamp on, and the levelling slab arranged beneath it. This forms, perhaps, the most comfortable arrangement that can be devised at a very little cost.

Before proceeding to coat, wipe the outside of the coating pot if it has been standing in hot water, otherwise some of the adherent water will find its way on to the plate with the emulsion, and cause inequality of film, if nothing worse. Having a stack of clean plates within easy reach, take up the first, pass a broad camel-hair brush once over the surface, and then with the glass balanced on the tips of the fingers of the left hand, pour a good supply of emulsion, sufficient to three-parts cover it, on to the centre. Incline it very gently in the direction of each corner to allow the emulsion to flow right up to the edge without running over, and return a portion to the coating vessel, without attempting to drain closely. Experience alone can educate as to precisely how much emulsion to leave on, but after a few trials the eye and hand will fall into the trick.

If from any reason, such as the emulsion having fallen too low in temperature, it should refuse to run freely, it may be led over the plate with the finger—I have never found any harm arise from using that handiest of instruments for the purpose—and the bulk of emulsion allowed to flow over the spot to equalise it before pouring off the surplus. If by any chance an air bubble should make its appearance, it may be led off to the edge in the same manner, but this is only likely to occur from careless pouring.

In placing the plate on the slab it should be tilted as little as possible—indeed, after pouring off the surplus emulsion, it must be restored to the horizontal position as quickly as possible, and a gentle rocking motion given to level the coating before placing it on the slab. This should be so arranged that the hand can get below its level so as to slide the plate on without any tilt. With but little practice the various manipulations at this stage will become perfectly easy. Proceed in the same manner with succeeding plates, placing each one on the level and pushing the previous one further on until the row is full, and when the slab is fully occupied transfer the lot to the drying box and start afresh, returning the coating pot to its hot water bath in the interval.

With regard to drying it is not my intention to describe any elaborate arrangements, as those who wish to go to the trouble and expense will find numerous such described in past ALMANACS. For amateur purposes all that is wanted is protection from light and dust, and as much air space as possible. An empty packing case, lined inside with paper and provided with a curtain to cover the front, will answer every purpose. If only a few plates have to be dried at once they may be reared on edge round the sides; larger numbers will require some simple form of rack, or, better still, narrow shelves may be nailed round the sides of the box to provide more space, and the surfaces of the plates will then be more freely exposed. In such a chamber, if not too closely packed, the plates will dry in less than twenty-four hours without further assistance.

I had intended to finish my series of articles this week, but have so far overrun my space that I must postpone development, &c., to another.

C. BECKETT LLOYD.

IMPRESSIONS BY A PROVINCIAL.

ONE of your contributors complained a little while ago of the scarcity of exhibitions in his part of the country. Some such reason, added to others of a business nature, caused a brother benedict and myself to find excuse for a short trip to the Metropolis, our object being to examine thoroughly the Exhibition at Pall Mall, with a view to future triumphs; to worship at the shrine of Saint Robinson in Bedford-street, not to mention other saints and shrines in other places; and to try and find out what these naturalistic cranks want to be at.

Our first impression (not altogether mitigated by a second and third view) was one of disappointment at the Pall Mall Show in negatives, printed in platinum or silver (the former mostly), without apparently any thought, in most cases, of their suitability for the one process or the other. Miserably poor, funereal, and gaudy frames stared at us from all sides, while many of the photographs themselves might well have been allowed to remain below "unseen, unhung, and unwept," their places being taken (if the object was to cover the screens) by some charming views from the Society's portfolios; these latter well repaid inspection.

One of the best pictures was undoubtedly Sawyer's *Dangerous Company*. I heard some one criticising unfavourably the "working up" on this; all of it, in my opinion, perfectly justifiable. This person was evidently a "naturalistic;" and here I may say that if the "faddists" above referred to have nothing better to show than, say, No 489, negative by P. H. Emerson, or various whole-plate platinotypes served up "hot," by G. Davison, the sooner they are rusticated the better. Most of them wanted a more liberal application of the trimming knife. But the remembrance of No. 489 is like a nightmare.

The ways and vagaries of Judges are most mostly beyond the comprehension of ordinary individuals. For instance, one could not understand why the beautiful productions of Van der Weyde were undecorated. From several points they were much superior to the "Cologne" artist's. The Autotype Company have obtained a medal, although I failed to discover anything extraordinary about their work other than the size. The man who supplies the negative is seldom thought of.

Mr. Ralph Robinson is a most prolific exhibitor, and shows some excellent landscapes, one of which we thought more deserving of a medal than the *Artists at Home*. We were glad to see McLeish's photograph, *Sympathy*, which we thought a distinct advance on some of his medal work. We wanted particularly to see the portraits, but apart from Mr. Baker's, No. 639, portrait in carbon pastel, those of children by Gunn and Stuart, No. 404, and two charming studies by Mrs. Edward Penton—charming in spite of their miserable frames—we saw nothing extraordinary. To see the best in portraiture, we had to perambulate Bond-street, Regent-street, and Piccadilly.

Strange ideas seem prevalent with regard to mounts. The rush for India-tint plate-impressed mounts is rather overdone, and the photograph is still trimmed to suit the mount, and not the picture. It would be far wiser to fall back on the plain cut-out mount.

The show at the Camera Club was another disappointment—picture speaking, of course; very interesting from the historical point of view. Almost any one of these pictures would be "immense" by itself, but a collection of them! I suppose these "one man shows" are a success, but how wearisome for many of us. Sutcliffe's studies are all worth seeing, a few at a time; but I am glad now that I did not see the collection lately on view. A one man show would be, I believe, more interesting if the work were more diverse in character—landscape, marine, architectural, &c.; and I could mention two or three who could provide such an exhibition, composed of good pictures throughout. I am afraid photographers, as a rule, are dreadful plagiarists, imitating and repeating themselves as often as, and oftener than, their neighbours.

The crush at the lantern demonstration, though very unpleasant, proved the popularity of these entertainments. While at the meeting on Tuesday we were pleased and interested to see, and meet, and rub shoulders, with men whose names are household words with all enthusiastic photographers. And we return to our little town, feeling that the Exhibition just closed, good as it may be, is hardly worthy of our Parent Society, and feeling, I am glad to say, not at all disheartened at the qualities of our own work at home.

D. D.

COLOURED PHOTOGRAPHS.

XIV.

IN our last paper we treated of the making of our sketch, and left it ready, or nearly so, for colouring. It is always an advantage, even when we have a photographic base to work upon, to be able to make a sketch from nature. Indeed, in cases where we are not obliged to

but have a photograph to work upon, this knowledge will be found more than useful. As I before suggested, it will be the artist's knowledge backed by skill that will give the intrinsic and artistic merit to a painted photograph. If three artists of three varied degrees of excellence were to paint three enlargements of the same subject, there would not be the least trouble in classifying them correctly from the results. No sound artist could be overpowered by the presence of a correct and elaborate sketch; then why should he be by a photograph, which I hold would be to him as nothing more or less than such? The trouble might be, and no doubt would, if the photograph were to be on an unfavourable texture, which would be antagonistic to an artistic result. If, for example, we had to paint in oils a portrait of a very forcible face on a very smooth surface, that would not take the colour kindly, we might fail in vigour; but there is no reason why we should be subjected to these disadvantages. With modern improvements, the requirements of an artist can be gratified in every way, whether for water-colour or oils.

Of course, there is a vast difference between painting in water-colours and in oils. Still, many of the principles as regards colour are the same, the difference being more in the treatment. In water-colours the lights in a face, for example, are transparent, while in oil-colours they are opaque. In oils, the transparency (a quality most desirable if not absolutely indispensable) of the shadows is preserved by placing one layer of colour over another, care having been taken to allow the first coat (so to speak) to become thoroughly dry before applying the second, and so on. By this treatment the colours first applied will show slightly through the second layer, and this not only produces transparency, but also secures depth and beauty. Nearly all the colours used in water-colour painting may be said to possess more or less transparency. Chinese white, of course (if I may class it as a colour), does not come under this condition, since it is unmistakably opaque. It is, however, little used in flesh work, so it matters not very much. In working water-colours you will find we must vary our methods of working, as we cannot possibly gain the same effects and results by the same treatment. Needless to say, whether on photographic base or otherwise, water-colours do not adhere to the surface upon which they are used with anything like the firmness of oils. As a consequence, we cannot gain either transparency or depth by washing one colour over another, even when the first washes have had ample time to become perfectly dry. The cause of all this is very simple, if we only reflect a little. The gum which is more or less used in all colours, and which bound, as it were, the first layer of colours, would on the second application become dissolved, and instead of two distinct layers we would have a mixture.

It may, perhaps, be worth while to give an example of this, as the fact is well worth bearing in mind. Now suppose, in oils, we place three coats of colour—blue, red, and yellow respectively (of course, having given number one time to thoroughly dry before passing number two over it, number three following under the same condition)—a compound tint will be the result, which will partake of all the three, the last applied naturally predominating. If we alter the rotation in which we placed the colours, leaving either blue or red to be the last or uppermost, we will still have a compound colour, but the tint will be quite different from that when yellow was the last applied. Now with water-colours the result is altogether different. Suppose we wash the same primaries in the same order; they will not remain, as it were, distinct, but, on the contrary, they will mix and unite, and darkness—I was almost going to say blackness—will be the result. This result, too, is but little altered by the rotation in which we apply the washes.

In order, therefore, to secure anything approaching to the transparency and depth of oil-colours, the water-colour artist is necessitated to use the somewhat tedious alternative of stippling or hatching the several colours separately, in their purity, and so produce the compound tint. It will be found that the primitive colours applied in this manner will always be more brilliant and effective than the same colours if previously mixed into tints and then applied.

Many of our greatest artists and best colourists preferred working these three colours in their purity rather than by compounding their tints. If I mistake not, Sir Joshua Reynolds and also Hogarth were in the habit of working in this manner. The great Rubens, too, advocates this principle. He is reported to have said, when instructing his pupils, "Paint your lights white; place next to that yellow, then red, using dark red as it passes into the shadow; then with a brush dipped in cool grey pass gently over the whole, till they are tempered and sweetened to the tone you wish." Of course, these remarks by the great master were made in application to oil-painting, but the principle is applicable to all colouring, and will be seen to apply to water-colouring as we go along.

To stipple is to apply the colour to the part to be painted by means

of a number of more or less fine dots, with the point of the brush. Hatching is to gain the same effects, but by a series of lines instead of points. Stippling may be said to be almost always the same, varying almost only in its degree of fineness. Hatching, on the contrary, is a much more varied style of work, probably nine out of every ten artists having their own particular and peculiar methods, and all good. I will try to describe what I think may be considered as a fair sample of this class of work.

First, we must start by working over the portion of the face to be covered with colour by means of a series of strokes, short, wide, regular, and somewhat horizontal. These should be worked in rows from the top downwards, and should be put on with a certain degree of firmness. Care should be taken to avoid having little blotches of colour at the end of each or any of the strokes, and they should (the strokes, not the blotches) run, as much as possible, in the same direction as the natural fibres of the skin. As a result of observation, we will find this to be, more or less, horizontal on the forehead, perpendicular on the nose, and round the eyes, mouth, and general contour of the face, circular. Naturally taste and judgment must considerably temper this treatment.

As I said, care must be taken to avoid the little blotches likely to form at the ends of the strokes, and which are sure to bother, as well as mar, the work of the beginner. In order to avoid these blemishes I would advise using the colour rather dry, and not carry too much in the brush at a time. It is wise, also, to press firmly on the brush at the beginning of the stroke, and becoming lighter as we get to the end, and not fall into the error of beginning lightly and developing courage and firmness as we get to the end. It may appear very foolish to do the latter, but I assure you it is much more easily done than appears at first sight. When we have successfully hatched the strokes firmly and evenly one way, we must now cross them with the same crisp, firm, and even touch, taking care never to cross them at right angles, or with strokes that are too oblique. This done successfully, a very light and mellow effect will be produced.

All hatching should be comparatively open, but not to a very remarkable extent. All shadows worked in this way will possess great depth and brilliancy, giving the spectator the idea that he can almost look into them as it were. Now, this is an effect that never can be gained by any number of so-called flat washes of colour.

There is one rule in water-colour painting which should be kept constantly before the student's eyes, and that is that the first colours to be used should be bright and pure; because, however much they may appear out of place, they can always be lowered to the desired tone afterwards. If, on the contrary, their brightness and purity be once sullied by thoughtless admixture with other colours, it will be found impossible to ever restore these most essential qualities. There are no qualities which impart such style and beauty to a picture as purity and brightness, nothing that can compensate for their absence.

To any one intending seriously to take up portrait painting, I would recommend a thorough study of light and shade. There are few, if any, things in nature which offer such endless studies of light and shade as the human face. Its varieties are exhaustless, and should claim our very best attention. If the human face were a flat surface, without either projections or depressions, one uniform flat tint or wash of flesh colour would prove all that was necessary in painting a more or less faithful representation of it. But it is not so; there are numerous little delicate undulations and markings which must all be secured and adequately treated, or else a meritorious portrait will never result. Indeed, the gradations of light and shade on some faces are almost innumerable. These are no end of trouble to the would-be artist, but to the really capable one they are sources of enjoyment, for he thoroughly appreciates their value and importance. For the study of light and shade, I would advise the student to have a white plaster cast, and keep it always handy when working as a kind of reference. I recommend a plain white bust for the study of light and shade, because it will be best understood when uninfluenced by the presence of colour. This study of light and shade is of such importance, that I do not think any student fit to proceed with the colouring until he has thoroughly mastered it.

Light and shade are the two great means used by nature to effectively relieve one object from another. If we observe closely the objects round about us, we will find everywhere that light is opposed to dark, and dark to light.

All objects in the open air will be found to throw shadows of considerably less force than those indoors; this is the result of the former being lighted more broadly. They have the reflection of the sky and also of the surrounding objects to aid them, while within doors the light is necessarily limited, and the reflections consequently less apparent.

It will be observed that the real colour of the majority of objects is most discernible in their middle tints. Strong colours are best adapted to the parts nearest to the eye; receding objects are proportionately fainter in colour than those nearer to the eye. Lights are very considerably less influenced by distance than are shadows, the latter growing paler as the distance increases. It will be remarked that the highest lights possess but very little colour; the deepest shadows absolutely none.

It must be remembered that all retiring parts partake somewhat of a greyish tone. Strong shadows should, in almost all cases, be *warm*: those of the flesh always inclining to *red*. All shadows of flesh must have *grey* edges, which naturally lends great richness, and at the same time does away with the hardness that would otherwise exist. All reflected lights of flesh will be found warmer than the neighbouring parts. The darkest parts of deep shadows will be found near their edges, the centre being relieved by the fact that it is lighted somewhat by reflected light.

The next stage is to prepare for active operations by placing the colours upon your palette. It is usual to set a palette when about to start *flesh* painting. For this purpose place the following colours in your palette, the lightest being near your thumb:—Indian yellow, Venetian red, vermilion, pink madder, brown madder, Indian red, Vandyke brown, cobalt blue, and sepia.

I only mention these as a most likely lot of colours, and ones by the use of which all flesh tints can be obtained. I do not at all wish to suggest that really good flesh tints cannot be made from the combinations of other reds, blues, and yellows. I may here say that almost every artist has his own special idea about colours, and makes up his palette accordingly. Many artists use colours of what we term a *low tone*, such, for example, as yellow ochre, indigo, light red, pink madder; while others fly to the other extreme and employ more brilliant and showy pigments, and never take into calculation the fact of their lack of durability. I need not say that this is not only a mistake, but a pity as well; for the work produced may be very good indeed, but in the lapse of time will not be fit to look at, and thus a work of art will become gradually useless.

Some artists use the colours *pure*, while others mix different *tints*, such as Indian yellow and Venetian red for the flesh colour; pink madder and vermilion for what we call the *carminations*; brown madder and pink madder for the strong markings of the lips and nostrils, and Indian red and blue for the shadow colour; blue and yellow for the green tints or greys, and all of which can be mixed when required for use. A small palette is best for this work, and it will be found an advantage to set apart one specially for this purpose. When using it, always keep a portion (say the centre of it) perfectly clean for mixing the various tints. Much of the success of a picture depends upon the fact of your keeping all your flesh colours bright and clean.

REDMOND BARRETT.

PERIPATETIC LANTERNISTS.

ADVERTISING transparencies are now to be seen on tops of houses, or inserted in the place of windows, in many of the principal thoroughfares of London, and the interest they create is evidenced by the number of people who stop to witness the succession of displayed and pictorial trade, theatrical, and other announcements. It has been left to the ingenuity of some one to further develop the idea by getting over the difficulty of finding suitable premises where people most do congregate by arranging a *travelling* exhibition.

From an advertising point of view the idea is good; and, although the instance I have in mind was only on a small scale, and without much "art" in it, there is no reason why a capital commercial speculation should not result from it, with care and attention given to details.

While strolling home one evening down a busy thoroughfare, full of fine shops (which are always an attraction to persons living in the suburbs of London), I came on a large crowd of people at the corner of a street running out of the main thoroughfare, and having previously seen the position occupied by a Punch and Judy show, thought it was a repetition of this ever-popular entertainment; to my surprise it was a magic-lantern display. I was naturally curious, and found, after waiting a little while, that a number of advertisements where projected on a transparent screen fitted into the back of a small hooded cart—the disc being about six feet in diameter. Judging by the light, the lantern employed was one with a three or four-wick paraffin lamp. Besides the advertisements, a series of comic slipping slides were shown for the amusement of the juveniles, and, possibly, the children of larger growth.

Here is a chance for the photographer who has not enough to employ his time, or sufficient business in the orthodox line "to fill his

coffers," to take up; but it should be done in a good style, and pictures, not daubs, shown in between the advertisements. While there are Pears', Beecham's, Cadbury's, and a hundred others only too anxious to outvie his competitor in his own particular line, there should be no difficulty in getting fees sufficient to pay all working expenses and show a profit, besides the opportunity it will afford the photographer (and manipulator of the apparatus) of making their whereabouts known to an extensive circle of possible customers. With compressed gas in cylinders, and a magic lantern having short-focus lenses, a capital result could be obtained in a hooded *van*, such as used in many trades (viz., millers, carmen, brewers, &c.), and which, no doubt, could be hired reasonably, by fixing a eight or nine-foot screen in the end in such a way that the hood afforded a little shade in case of any accidental side glare. The light of about 400 candle-power, thus produced by making the lime incandescent, would be equal, when passed through the condensers and projected on the disc, to over 2000 candle-power, and fully capable of withstanding a moderate amount of street illumination. To get the best effect and greatest transparency, the slides should be produced by the wet process; and preference should be given to bills having strong contrasts, or pictures of a bold character, having either transparent colours or photographs with high lights and deep shadows. The pictures should be produced as large as the condensing lens will cover, so that the objective has not so much to do to magnify them to the necessary size. For instance, if a four-inch condenser is used, the circular mat should be three and a half inches in diameter. In copying coloured posters care must be taken to neutralise those colours that photograph black, such as red, and otherwise, to get the glass positive as transparent as possible.

As it is generally admitted "that you must advertise if you want to be known," I think the idea here enlarged on should be a practical means to that end; and, if done in good style, need not be *infra dig*.

G. R. BAKER.

DETECTIVE CAMERAS.

THIS year has been marked by the rapidity with which the adoption and use of detective cameras has proceeded, and as it is probable that next year will see a still farther increase in the use of this most convenient form of camera, perhaps a little sketch to show what has been done in the manufacturing line to render the instrument as perfect as possible, and to point out in what direction we are to look for improvement, will prove of value.

I am referring not to those all but useless dodges which are hidden away under one's clothing with a lens poking out of a button hole, but to the really serviceable kind intended for producing pictures for enlargement or for lantern work.

The name "detective" has been given to this class of camera, I know not why, for I have never yet heard of a detective using one, or of any photographs taken with one being used as evidence in a police court, but it seems likely to remain, though for my own part I should be glad to see it replaced by the term *hand* camera.

A hand camera is primarily intended to take advantage of the rapidity of gelatine plates and the perfect state of rapid shutters, and to do away with the use of an awkward tripod and focussing cloth. This most important step taken, the remaining parts—for small sizes at least—can be enclosed in a box, thus no time is lost in racking out for focussing, and unscrewing this and screwing up that when an object presents itself. If very rapid work is attempted all is ready before the object comes within range, and it is only necessary to present and release the shutter.

The advantage of this arrangement is very obvious, and many results may be obtained which are quite out of the question with tripod and focussing cloth; for instance, I have a little picture which I entitle *A Warning to Young Ladies*—a stout young "cleric" seated on a camp stool, with ample coat tails falling behind, and reposing in folds on the deck—for the view was taken on a steamer—is chatting lightly with a damsel in a white well-fitting dress. The day being hot and sunny a sunshade casts an acceptable shadow over both, and their heads are close together; in fact, a mild flirtation is proceeding, and though I have obtained only a back view, it is most characteristic. Now imagine a gentleman on a well-filled steamer fixing up a tripod and camera and pointing it deliberately at the back of such a couple, it is highly probable that while his head was under the focussing cloth he might imagine that a thunderstorm had come on. But to become serious once more, I was staying this year at Southport which is some little distance from Liverpool, and in two visits to the latter place I managed to get a series of views of the docks, &c. which would have been—if not impracticable—very difficult to obtain with an ordinary camera; in fact, I believe an order would have been

necessary for photographing many of the docks. Again, in each of my two visits to Liverpool I was most fortunate in finding one of the two new Inman Line steamers of over 10,000 tons anchored in the Mersey—first, the *City of Paris*, and, second, the *City of New York*—of which I obtained good shots from the ferry boats.

Hand cameras are, I believe, made in many sizes larger than quarter-plate, but I am inclined to advocate this as the most convenient size; for most shots will bear enlargement up to 12 in. \times 10 in., and really sharp negatives to considerably more; and as many photographers (amateurs at least) go in for lantern work, reasonable-sized pictures are obtained for printing, and a convenient size for direct lantern-slide making. Now, starting on the basis of quarter-plate, let us consider what are the chief requirements for general work.

Lenses.—We will start with the subject of lenses, which is all important; without a good lens first-class results cannot be obtained. Mr. Traill Taylor has entered into the subject of the best class of lens for this purpose very fully in a paper read before the late Convention and published in this paper, so in view of this we will at once recommend the rapid rectilinear type to those who can afford it, and the single non-achromatic lens to those who require a cheap form, cautioning users of the latter to note that the focus as obtained on ground glass is not the chemical focus, and that it is necessary to shift the plate about one-thirtieth of the total focal distance nearer to the lens; this is of no consequence when the focussing is done by the use of a graduated scale marked with distances. The next point to be considered is what the focal length of the lens should be. Some recommend the use of a wide-angle or short-focus lens, and others the reverse, i.e., long-focus lenses; but it must be borne in mind that with a wide-angle the size of the object diminishes with great rapidity as the distance increases, and it is, therefore, necessary to be very close to the object if it is to be of moderate size on the plate and is not of large dimensions. The exaggerated perspective given by this class of lens is great, so that the idea of the distance of an object is very erroneous. But there is one point of advantage that it has over long-focus lenses; it is that the depth of focus is considerable, and therefore practically no focussing is required. The longer the focus of the lens the larger is an object at a given distance rendered on the plate, but the depth of focus diminishes with the length, and though the object be sharply focussed the distance is blurred, unless the lens is considerably stopped down; but I think that in some cases the blurring of the distance is of advantage, as it gives an idea of solidity to the main subject of the picture. As focussing by distance is not difficult in this kind of camera after a little practice, I am of opinion that, for general use, a lens of less than five inches focus should not be used on a quarter-plate, and no advantage is gained by employing one of more than seven inches focus.

Now, as we see that under certain conditions a wide-angle lens is of value, and under other conditions a long-focus lens is necessary, why not combine the two desirable qualities in one lens? It would be a very simple matter to make the front combination of a doublet lens moveable, and then by shifting this with a small lever the back combination will serve as a lens of double focus, so that if our doublet lens is of three inches focus the back combination alone is of six inches focus.

As to stops, more than three are unnecessary, beyond full aperture the ratios being as one is to four. With a rectilinear type the iris diaphragm should be used, as it adds but little to the first cost, and is of incalculable value when rapid adjustment is necessary, the movement of the end of a little lever along a scale attached to the outside of the box completing the adjustment. With the shifting combination lens described above, two scales for the iris diaphragm would be necessary.

Shutters.—The question of shutters most undoubtedly comes second in importance. First, the shutter should be adjustable for speed. I have lately seen a hand camera which has a shutter fitted which is not adjustable, and works at about one-fiftieth of a second; the full aperture of the lens is $f/16$, and three more stops are provided. Now, for an open landscape, in bright sunshine, at the best time of the year, with plates of fifty times—oh, how indefinite!—to get out detail thoroughly satisfactorily I do not find one-fiftieth of a second, with an aperture of $f/11.2$, too much. Now, how is my friend to get satisfactory results with his arrangement? I need hardly say that he does not. It is so easy to make a shutter adjustable within limits by a friction brake or an air brake, or by increasing or decreasing the tension of the motive spring while it is under course of construction, that I am surprised that every shutter has not the necessary means attached. With hand cameras it is not necessary to consider the portability of a shutter, as there is always ample room somewhere inside the box to dispose of it, and thus, as long as it is serviceable, it does not matter if it is clumsy.

The shutter must not kick with rapid exposures, for a double image will certainly result if this is the case; therefore, the opening and closing of the shutter should be completed before its motion is impeded. My shutter is a curved strip of thin sheet metal with a hole through the middle, equal in size to the full aperture of the lens. This passes between the two lenses through two slots in the mount a little in front of the iris diaphragm; it is worked with a small annular spring, and an air brake gives the means of adjusting the speed. The cap for regulating the admission of the air passes through the bottom of the box, where a small scale indicates the different speeds. I can work it at speeds varying from one-eightieth of a second to one second, and if time exposures are required it can be stopped half way. Now this shutter is all that can be desired, the only possible objection that can be found with it is its size; but this, as I have shown, is of no consequence in the class of camera under consideration.

The release button or pin should be placed in such a position that a finger of the hand holding the box naturally falls upon it, and it should not be stiff or awkward in use, for there is every chance of moving the camera if a sudden movement or jerk is necessary.

The plate-holding arrangements are very numerous, and frequently form subject-matter for patents. The most convenient is, of course, the roller holder and flexible film, as to change the surface it is merely necessary to turn a little key outside the box. But as we have not yet obtained a perfect flexible negative film, the greater number of hand-camera users are content—nay, prefer to use ordinary glass plates; and I think, notwithstanding that many ingenious dodges have been installed which are supposed to be preferable to the old double darks, that the double darks still hold their own. Of course, the double darks for holding celluloid films are much thinner than those for glass, and are very much lighter, so that a greater number of plates may be carried weight for weight and size for size; but it is sometimes of considerable disadvantage, in point of extravagance, to have a number of plates at hand, for the most experienced photographer will often become careless as to what he exposes his plates upon if he knows that he has a large number to fall back upon. If celluloid films are to be used, I would suggest that instead of cramming a large number of holders into the space which would hold six glass-plate double darks, that the space be reduced to accommodate only six holders, and the whole camera made more compact.

The methods of focussing are numerous: the lens is sometimes moved, more often the plate is moved, and in some cases the box is made telescopic, so that both lens and plate are moved. Of these I favour the telescopic device, for with both of the other plans it is necessary that the box be made sufficiently long to allow of a movement inside of the adjustable part of at least two inches when a five-inch lens is employed, and when closed the telescopic box is therefore two inches shorter than the others.

The gain in portability by the use of this arrangement, combined with the three-inch shifting combination lens, is apparent. The focussing should be done always by using a scale marked with the focus of an object at various distances; this may seem, perhaps, to a novice a very uncertain method, but one can with very little practice focus accurately by distance. This is due to the fact that an error of one or two feet, in judging a distance of eight or ten yards, would mean shifting the plate with a five-inch focus lens less than one-one-hundredth of an inch. It will be found of no gain to focus by sight if the scale is accurately divided, and it is very awkward looking through an opening at the back of the box, and having to remove the double darks which are usually stored at the back of the box; perhaps it might be advisable to have such an opening in case it is necessary to take an object two or three feet distant, for then a slight error in judgment will be of importance.

Finders.—Many users of hand cameras deery the value of these, but, after some practice, I will pose as their staunch supporter. It is all very well to say that one can tell how much is taken in on the plate when the camera is pointed at a certain object; yes, nothing is easier when one has only to consider the breadth of the picture, but height is an entirely different matter—the necessary inclination is always varying. For example, I am taking a noble elm with a group of cattle resting in its shade: it is first necessary to determine the distance I must be away to get the whole in; this is by no means easy, as the height of trees varies considerably. Then, while feeling a little uncertain whether the distance is right or no, I have to determine the inclination. What wonder, then, that on developing I find that the cows have no legs! Now a glance at the finder settles the whole matter, leaving no room for uncertainty. It is to the finder that we owe the certainty of our results turning out pictures. Have finders by all means, but let them be such that the picture is clear and sharp, and that it gives a correct idea of what is on the plate.

I have lately seen two finders—one for vertical and the other for

horizontal pictures—carefully fixed to a hand camera that have the reflecting mirrors inclined at 30° to the ground glass, and a most remarkably poor lens. Puzzle—find the picture! If our friends who are independent of finders have their experience of finders limited to such as these, I sympathise with them. Really good ones can be had for 2s. or 2s. 6d.

It is sometimes necessary to use a tripod for time exposures, and then one which folds up as a walking stick will be found very convenient, but for general work it is as well to be independent of it, for it is quite possible to hold the camera steady for half a second. I have one or two sharp negatives taken with this speed. One-fifth of a second makes work a little more comfortable, and with one-tenth of a second one may depend upon sharp results without much care being taken in steadying.

To obtain secrecy, many ingenious dodges have been adopted, and I think this is perhaps a point best left to the user; but I have found that a box merely painted dead black has been the object of remarkably little observation, far less than I expected. I would remind new hands that it is not merely the device adopted that gives security, but also that the manner of the operator must be above suspicion. If a man with a picnic basket tucked under his arm is found sneaking about in a suspicious manner in a crowd assembled to witness a Royal procession, dodging first this way and then that, and looking in a most unguarded manner every moment at his finder, it will not be surprising if he is quietly touched on the shoulder by an unobserved but observant policeman, and requested to "walk this way." W. P. ADAMS.

SOME MEMORIALS OF DAGUERRE.

[A Communication to the Glasgow Photographic Association.]

In bringing before you this evening a few photographic illustrations connected with the later years of Daguerre's life, I have first of all to acknowledge the extreme courtesy and kindness of M. Davanne, president of the French Photographic Society, in presenting me with these interesting reminiscences of the illustrious Frenchman.

Daguerre, as all the world knows, was by profession a scenic artist. For one theatre especially, *L'Ambigu Comique*, he painted several important scenes, but his fame was more permanently established by the painting of those pictures which have received the name of dioramic, where, by different arrangements of light and shade, and by viewing the picture first by reflected and afterwards by transmitted light, various effects are rendered. To enumerate all the pictures Daguerre produced in this way would be to exceed the limits of the present communication, but it may be sufficient for our purpose to refer to the delineation of the Goldau Valley in Switzerland, where, early in the present century, a severe landslide took place, the appearance of the valley, both before and after the catastrophe, being shown to the spectator. Another famous effect was that of Holyrood Chapel; this picture earned for Daguerre the cross of the *Légion d'honneur* in 1824. His last work was the *Temple of Solomon*, and this was produced in 1839. In connexion with these dioramic effects Daguerre had associated himself with another artist of the name of Bouton. The diorama was first opened to the public on July 11, 1822, and continued to be one of the sights of Paris down to the year 1839, when, on March 3 of that year, the whole of the series of paintings were destroyed by fire. Daguerre did not attempt to reproduce any more of these dioramic representations, having been engaged in the securing his light-drawn pictures; with what success we are all acquainted.

The photographic print which I now pass round shows, perhaps, the only remains of Daguerre's handiwork to be found in France. If you were asked, What does that picture represent? the answer would be, The interior of some large cathedral. But it is nothing more or less than a painting. The circumstances under which it was painted are something like the following:—Daguerre, after he had received the annual pension of 6000 francs decreed to him by the French Government for his discovery of Daguerreotype, removed from Paris and settled down in the retired village of Bry-sur-Marne. Here he built a villa, where he spent the remainder of his days with his wife and niece. He married an English lady, Louisa Arrowsmith. The house itself was pulled down in 1870, having been acquired by a religious body. The only thing remaining as in existence in Daguerre's time is the handsome gateway erected by himself. This you will see a picture of by-and-by. Returning to the church picture: it seems the parish church at Bry terminated very abruptly almost immediately behind the high altar. By the expedient of painting on canvas an interior such as you see depicted, Daguerre increased the apparent size of the building; indeed, it may be said he more than doubled it. In making the connexion between the real building and the artificial one, Daguerre first drew in very high relief, on either side of the wall

behind the altar, a stone column. On one was painted a gilt picture frame with no picture in it; on the other a frame was shown with a representation of the Virgin. On each pillar a bouquet of roses was delineated, and from the arch above a crucifix was made to appear as if it had been duly suspended. All this formed, as it were, a starting-point—a sort of framework for the illusory nave, which filled up the centre of the canvas. M. Balagny, who photographed the picture, describes the illusion as most complete, and if the altar were not there to bar further progress, visitors would wish to penetrate to the nave beyond. It is to be noted that the effect described is to be seen from any part of the church. Daguerre, in painting, was careful enough to see that it should be so. His invariable habit, after almost every stroke of the brush, was to retire to the various parts of the church to see the effect produced.

The next picture which I wish to bring under your notice is, as you will see, a representation of a kind of grotto. This was an arrangement erected on the grounds of Daguerre's friend, Baron Louis de Bigny. In 1848, during one of those revolutionary periods to which France seems to be periodically subject, the inhabitants of Bry-sur-Marne were in somewhat sore straits: many of the villagers were employed in the park of Bigny, under Daguerre's superintendence, in making a sort of miniature Switzerland. The photograph gives a very good idea of what the nature of the work would be. It is somewhat theatrical in effect, this grotto, but I have no doubt it will form a cool retreat on a hot summer's day.

We have already referred to the fact that Daguerre's house is no longer in existence, but, as also noted, the gateway to the house remains. In the print now sent round you have this gateway shown, while on the right of the picture is seen the small parish church of Bry-sur-Marne.

The remaining photograph connected with Daguerre and Bry-sur-Marne represents Daguerre's tombstone. It is a plain, square stone (presumably of granite), having a medallion of Daguerre carved on the side—represented in the picture. This was the work of M. Hussion, and is said to be a faithful likeness. The inscription underneath the head reads as follows:—

"À.

DAGUERRE,

ARTISTE, PEINTRE, CHIMISTE.

L'INVENTEUR DE LA PHOTOGRAPHIE.

LA SOCIÉTÉ LIBRE DES BEAUX-ARTS.

1852."

From which it will be seen that this commemorative stone has been erected by the Society of Fine Arts, of which Daguerre was a member. The other sides of the stone have also inscriptions: one, "Sciences, Beaux-Arts;" another, "Diorama-Daguerreotype;" and the remaining, "Le Consul Municipal de Bry à Louis Jacques Mandé Daguerre, né à Cormeilles en Paris le 18 Nov., 1787; décédé à Bry le 10 Juillet, 1851."

We now leave Bry-sur-Marne to turn to Cormeilles, a town which has the honour of being the birthplace of Daguerre. A very handsome monument was erected to the memory of Daguerre in the year 1853, on a small square opposite the house where he was born. The funds were provided by those interested in photography in the various countries of the civilised world. It is a pedestal some six or seven feet in height, and is surmounted by a bust in bronze, the work of the sculptor Capellaro. The print I now pass round shows this handsome memorial. The inscription is much the same as on the tombstone at Bry-sur-Marne, giving the facts of Daguerre's birth and death; while at the foot of the pedestal we find the inscription, "Souscription Internationale, 1853." It only remains to be added that the inauguration took place on Sunday, August 26, 1853, and the two prints shown are from negatives taken on that day, an interesting record of an interesting ceremony. "They manage these things better in France," is a saying we often have quoted, and I think in the matter of erecting memorials to their illustrious men we could borrow a leaf from the book of our Gallie friends. When are we to see monuments erected in this country to men such as Talbot, Ponton, and others, who have done as much towards the solution of the problems involved in photography as either a Daguerre or a Niepce?

Speaking of the latter brings me now to the end of my communication, and in connexion therewith I have only to place before you two very interesting prints, viz., the scene that took place at the inauguration of Niepce's statue at Chalon-sur-Saône. This event was celebrated on the 22nd of June, 1855. The artist who designed the statue was M. Guillaume, and the casting in bronze was from the famous workshop of Barbadienne, in Paris. For these interesting memorials I also am indebted to M. Davanne, and I

think I cannot do better, by way of conclusion, than ask you to record a vote of hearty thanks to that gentleman for the favours conferred.

I have reproduced all the various prints as lantern slides, so we will have the lights turned down, and we will be able to see at one and the same time each particular subject.

WILLIAM LANG, JUN., F.C.S.

AN EPISODE.

TIME—AFTERNOON TEA.

By an Amateur.

Florence Ayebecce.—Oh, mamma, that nice Mr. Chocum has taken four lovely views of the church for our bazaar next month!

Mrs. A.—I forget, Florrie, what your next bazaar is for.

Florence.—The stray pigeons' home, mamma.

Georgie.—Pa says its humbug! He says pigeons are 'ticed there, and shut up till they forget where they belong, and then they stay there.

Mrs. A.—Rude boy!

Florence.—And, ma, he says he will give as many copies as can be sold, and a set to each of the stall keepers. They are two insides and two outsides—and so large!

A parrot.—He's a fool! Polly wants a cake!

Florence.—And, ma, he asked me when I had my last portrait taken; and said he would take me and Georgie also; and he would be glad to see you with us whenever you would call. He said he had a beautiful place in his drawing-room, with the light as good as a photographer's studio.

Mrs. A.—It is very good of him; but, Florrie, portraits by amateur gentlemen are seldom so smooth and bright as the regular people's.

Florence.—I asked him about this, and he said he should send the glasses to a person who got a living by making them smooth. He called it retouching.

Parrot.—He's a fool! Polly wants a cake!

Georgie.—I shall be smoking a cigarette. I shall.

Mrs. A.—Be quiet, sir! You will do nothing of the kind. You will sit still, and wear your new necktie.

Florence.—I told him, mamma, I was ashamed to have all these, as they must cost him so much; but he said I was mistaken—photography scarcely cost anything. He said less than a doctor's lotions and mixtures.

Mrs. A.—Then what a shame; that man Reeton charged me 15s a dozen for the last cabinets I had, and seemed to think it hard to take me a third time for a decent expression!

Florence.—But they are very nice, mamma.

Mrs. A.—Perhaps so; but no more Mr. Reeton for me!

Florence.—Mr. Chocum offered to take the curate to sell at the bazaar, but the vicar heard of it, and said he hoped Brightman was not such a simpleton as to let him.

Mrs. A.—By the way, Florrie, keep all mention of this from your pa. Some one has told him that amateurs ruin professional photographers' and he disapproves of it.

Parrot.—Polly says ditto! Polly wants a cake!

Georgie.—Pa says Mr. Chocum's a jackanapes!

Mrs. A.—You rude boy!

Georgie.—He says six hundred a year made a fool of him! If he had to work for a living he would do less harm to other people!

Enter Mr. A.—Eh? What?

FINALE.

Foreign Notes and News.

The Photographic Society of Amsterdam very praiseworthy appears to consider it part of its functions not only to stimulate and diffuse interest in photography by means of meetings and discussions, but from time to time institutes competitions and distributes prizes. Last spring it offered four silver medals as prizes for the best Dutch landscape, the best foreign landscape, the best instantaneous view, and the best detective camera photograph respectively. The competitors were to send in their specimens by October 15. This was duly accomplished, and Messrs. Bakhuis, Lentz, Beduin, and Bloemendaal, emerged from the criticism of the jury as prize-winners.

Luz, the very appropriate name of the official organ of the above-named Society, further informs us, with some show of satisfaction, that Loman's

reflex camera is gradually making more and more way in Germany. As it is one of the most perfect models of a hand camera in the market, this is not much to be wondered at, and we shall very probably before long become pretty familiar with it in this country as well.

It will be of interest to readers of the JOURNAL to learn that at the last meeting of the Society for the Promotion of Photography in Berlin, a special resolution was put and carried, on the motion of Herr Jahr, that THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1888-1889 should be added to the library of the Society, and that it should be taken regularly every year in future.

THE dark chamber glass difficulty has been making itself felt in Potsdam as elsewhere, Dr. Miethe declaring that he has been unable to discover any fit for use throughout the length and breadth of that town. After a spectroscopic examination of the different kinds he was obliged to throw them all away. For his dark chamber, which he also uses for preparing and drying emulsions, he employs a light placed behind a sheet of white paper over which is stretched cherry-coloured and canary-coloured chagrin paper. "This," says Dr. Miethe, "gives a perfectly safe light—so safe that dry plates may be exposed to it for an hour without clouding!"

PICKERING'S caricatures, obtained by means of crossed slits, appear to owe their origin to a French discoverer, Ducos du Hauron, who first described the phenomenon and showed that as the front slit was horizontal or vertical, a broadened or lengthened-out image was obtained.

FROM Herr Vogel's recent researches it would appear that Gädick's monochromatic soda flash light acts very well with ordinary plates, but does not give good results with orthochromatic plates.

CAPTAIN MENSINO, who is a member of the committee of the Society of Friends of Photography, has been invited to attend the International Navigation Congress at Washington.

THE well-known firm of dry-plate manufacturers, E. Kaders, in Dresden made October 26 last an occasion of merriment and rejoicing, which was probably not unaccompanied by the internal administration of alcohol not in the form of an emulsion. On that day namely they despatched their fifty-thousandth case of plates since their establishment in 1867. Our readers will doubtless join in the wish that their future may be as prosperous as their past has been.

W. CRONENBERG gives the following recipe for a gold bath for Aristo paper, which the Editor of the *Wochenblatt* says he has found to give very fine deep tones:—

A.	
Distilled water	600
Ammonium rhodanate	27.5
Phosphate of soda	30

B.	
Chloride of gold (doubly crystallised)	1
Distilled water	100

Both solutions must be allowed to stand for a day and a half. Before using, add fifteen parts of B to one hundred of A. Let it stand for an hour and then use.

Our Editorial Table.

DIE PHOTOGRAPHIE MIT BROMSILBER-GELATINE.

By LUDWIG DAVID and CHARLES SCOTIK. (Halle: WILHELM KNAPP.)

WE have received the first volume of the second edition of this excellent publication, which has appeared almost contemporaneously with the fourth edition of Dr. Eder's great work, dealing with the same subject, namely, photography with bromide of silver gelatine. The whole is divided into six parts:—1. Manufacture of bromide of silver emulsions. 2. The employment of gelatine plates. 3. Orthochromatic photography. 4. Failures and methods of preventing them. 5. Collection of receipts, &c. 6. Instantaneous photography—of which the volume before us embraces the first two. The present treatise being, as it is, the combined work of an eminent professional and an eminent amateur, is mainly distinguished by its high degree of practicability, being based almost entirely on the personal experience of the authors.

Both those commencing the manufacture of dry plates, as well as those who have a varied experience in the same direction, will hail its appearance with satisfaction, and it will in all probability form a standard work of reference for those engaged in this branch of industry. The first part comprises an exhaustive account of the various processes of manufacturing gelatine plates according to the three principal methods in use, namely, Monckhoven's, Henderson's, and Eder's boiling method, together with descriptions and illustrations of the plant and apparatus in use in large dry-plate factories. The second part forms an excellent treatise on development, well illustrated, and thoroughly up to date, and includes retouching, varnishing, and complete treatment of the negative. The extremely practical tendency of the work, and the capital way in which it is illustrated, would probably secure for it an extensive sale should it appear in an English dress.

DIE PHOTOGRAPHMETRIE.

By Dr. C. KOPPE. (Published by the Deutsche Photographen Zeitung, Weimar.)

A SCIENTIFIC treatise on the application of photography to scientific measurement, more especially in connexion with surveying. Indeed, the work before us more properly belongs to that department of technology. It is, however, interesting to the photographer from the considerations involved in the selection of means required to confer upon apparatus that degree of accuracy necessary for exact estimation of distance. Such, for instance, is the excellent chapter on the choice of objectives and the description of the photo-theodolite. This is an instrument, as its name implies, in which a small photographic camera is substituted for the usual telescope, and enables not only greater accuracy in measurement to be attained, but also obviates a great deal of the tiresome sighting and reversing which the employment of the ordinary theodolite involves. The book is an excellent example of that careful and thoughtful application of scientific principles to the solution of practical questions which has enabled Germany to make such rapid progress in all things technical. To such surveyors as have a tincture of photography it may be thoroughly recommended.

DIE AMATEUR PHOTOGRAPHIE.

By ROBERT TALBOT. (Published by ROMAIN TALBOT, 10 Bräuerstrasse, Berlin.)

A SMALL but most exhaustive pamphlet of some fifty closely printed pages, in which almost everything that one requires to know on the subject of photography is lucidly and attractively treated. The object with which it is written is, as we are informed by the unassuming preface, threefold. Firstly, to impart to those unacquainted with the art sufficient instruction to enable them, after a short time, to be able to use the camera; secondly, to give those already acquainted with the art an accurate description of the various forms of apparatus and processes at present in use; thirdly, to show architects, engineers, machine designers, &c., what assistance they may obtain from photography in copying drawings, plans, &c. A very cursory examination of the little work will show any one acquainted with the subject how thoroughly the two second objects are attained; and if success in regard to the first is less certain, it is not necessarily the fault of the author. One considerable advantage is that the theoretic and historical aspects of the subject are omitted altogether, so that wherever one opens the little work the eye lights upon something of practical value; and it is, besides being excellently and copiously illustrated, thoroughly up to date. It is offered at the modest price of one mark. An equally cheap and equally exhaustive practical treatise in English is still something of a desideratum.

PHOTOGRAPHISCHER ALMANACH UND KALENDER FÜR DAS JAHR 1890.

THIS almanac, published by Ed. Liesegang, Düsseldorf, Germany, contains several contributed articles, a compendium of the bibliography of the year, together with a list of the patents taken out in that country. It is printed in fine large type, and contains 140 pages, price one mark.

THE LONDON STEREOSCOPIC COMPANY'S FLEXIBLE NEGATIVE FILMS.

SINCE acknowledging the receipt of these films we have had an opportunity of fully trying them. They are coated on celluloid films, and as regards their flexibility they entirely bear out the accuracy of the descriptive title, seeing they can be bent into a curve and spring out again into their original flat condition. The sensitometer number of the films sent to us being twenty-seven, their value in obtaining fully exposed negatives during these dark November

days with a rapid exposure is something not to be lightly esteemed. In developing our negatives we first followed to the letter the instructions of Mr. John Carbutt, the maker, using the hydroquinone judiciously, according to the following formula recommended:—

A.	
Warm distilled water	20 ounces.
Sulphite soda crystals	4 "
Sulphuric acid	1 drachm.
Hydroquinone	360 grains.
Potassium bromide	30 "
Water to make up to	30 ounces.

B.	
Caustic soda in stick	1 ounce.
Water to make	30 ounces.

C.—Accelerator.	
Caustic soda	1 ounce.
Water to make	10 ounces.

D.—Restrainer.	
Bromide potassium	$\frac{1}{2}$ ounce.
Water	5 ounces.

Take of A 1 oz., B 1 oz., water 2 to 4 oz.—the first for instantaneous and short exposures, and the latter for time exposures, portraits, and views. For lantern transparencies, 1 oz. A, 1 oz. B, water 4 oz., D $\frac{1}{2}$ drachm. After using, filter into bottle for future use, and for starting development on time-exposed plates and films. With this we obtained negatives of singular excellence. We then tried a pyro developer taken from the formulae given in the last two or three ALMANACS, and having succeeded equally well with that, we conclude that as regards methods of development, the plates possess considerable elasticity in this respect.

BARNETT'S UNIVERSAL FILM CARRIER.

(The London Stereoscopic Company.)

ACCOMPANYING the above films we have received samples of Barnett's Film Carrier. They are light, and each is about the thickness of a glass plate. Formed of card, they have a light brass edging which ensures their being rigid. This edging also serves as a groove into which to slide the films, one of the ends sliding out to permit of this being done, afterwards closing tight over the end.

These film carriers greatly conduce to comfort in using negative films.

MARION'S FOCUSING EYEPiece.

MESSRS. MARION & Co. have sent us one of their new eyepieces for focussing. It consists of a magnifying glass set in a short tube, and this glass is capable of adjustment so as to suit any strength of vision. Its novelty consists in the way by which it can be attached to the focussing screen. This is done by a little pneumatic sucker projecting

slightly from the mouth of a shorter tube than the eyepiece, and to which it is affixed. Mere pressure against the focussing screen ensures the attachment of the eyepiece. Its nature may be further ascertained from the above cut. It must necessarily prove very useful and convenient.

NEW TRADE CATALOGUES.

THE catalogue of Messrs. McHie & Co., Glasgow, is remarkably elegant—our copy of it, at any rate, being done up in stiff boards, gilt lettered, and edged. It contains 116 pages descriptive of the lenses, cameras, general apparatus, backgrounds, and chemicals supplied by

this firm, and, being closely printed, this represents a large and complete stock.

Fallowfield's *Photographic Remembrancer and Traveller* for the quarter ending December marks a new departure, and is the first of a new series, which it is intended shall embrace a wider scope than hitherto. In addition to the various novelties of the past season, Mr. Fallowfield has impressed the muse into his service, there being two poetical contributions, respectively, *The Instantaneous Photographer* and *The Retoucher's Point*. This number includes the 114th page of this series of publications, and is quite equal to its predecessors.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 17,998.—"An Improved Plate Holder or Dark Slide for Photographic Cameras, together with a Swing Frame coupled with an Indicator, to be Used therewith in Cameras specially Made therefor or Adapted thereto." Complete specification. T. COLLEY.—*Dated November 12, 1889.*

No. 18,139.—"Improvements in Apparatus for Facilitating the Microscopical Examination of Photographic Pictures, Maps, and other Objects." H. DUNCAN.—*Dated November 13, 1889.*

No. 18,166.—"Improvements in Photographic Cameras." W. J. LANCASTER.—*Dated November 14, 1889.*

No. 18,167.—"Improvements in Photographic Camera Shutters." W. J. LANCASTER.—*Dated November 14, 1889.*

No. 18,224.—"Improvement in Photographic Shutters." H. G. M. CONYBEARE.—*Dated November 14, 1889.*

SPECIFICATION PUBLISHED.

1889.

No. 8274.—"Focussing Cameras." ELLISON.—Price 6d.

PATENT COMPLETED.

IMPROVING THE MEANS OF FOCUSSEING PHOTOGRAPHIC CAMERAS.

No. 8274. CHRISTOPHER OBER ELLISON, 62, Dale-street, Liverpool.—*October 26, 1889.*

THE use or attachment of a mirror or reflector to the outside of any kind or make of cameras having a focussing plate or screen at the back, so as to show the intended view as clearly as seen thereon, but the right way up—as in nature—instead of "upside down," as on the focussing screen itself, enabling the operator to artistically arrange and focus the subject in any easy graceful position, instead of the fatiguing and cramped attitude now so well known, and that without any change in or enlargement of the cameras, or the use of screws, levers, or other appliances liable to get out of order, and doing away entirely with the covering of the head, shoulders, and camera with the black sheet so annoying to lady and gentleman amateurs.

The mirror or reflector to be held or attached with rubber bands, or other means, to the back of the camera, so as to allow of the correct angle being obtained, and give play during focussing, and also allow of the mirror or reflector being swung out of the way when not in use, or laid flat against the camera for travelling, the light being kept therefrom by silk or other light material—or even a pocket handkerchief, so arranged as to be used with or without eyepiece or focussing glass, single or double, as preferred.

The mirror or reflector may also be hinged or otherwise attached to the frame of the focussing screen, so that both will swing out of the way together after focussing and remain ready for instant reuse, or lay against the camera as above, leaving no loose or unattached parts.

The claims are:—1. The focussing of any camera by means of a mirror or reflector on the outside thereof, showing the subject to be photographed exactly as upon the focussing plate—only the right side up, as in nature—and seen from the top instead of the back of the instrument, without any alteration or enlargement of the camera, the necessity for the use of any special camera, the use of screws, levers, or other appliances likely to get out of order, and without covering the head and shoulders with the black sheet so annoying to lady and gentleman amateurs. 2. The attachment of a mirror or reflector to the frame of the focussing plate, so that after focussing as above, both reflector and focussing plate can be easily swung out of the way together ready for instant reuse (leaving no loose parts to get mislaid), or laid flat against the camera for travelling. 3. The reduction of the weight of apparatus to be carried, and greater freedom from vibration of camera, by the use of shorter legs, owing to focussing from the top, instead of the back of the instrument.

[We are always very sorry to say anything that would have a tendency to damp the enthusiasm of an inventor, but we feel compelled to say that in an article entitled *How to Invert the Image on the Ground Glass of the Camera*, published in THE BRITISH JOURNAL OF PHOTOGRAPHY so long ago as August 30, 1867, and illustrated by a drawing, Mr. Ellison has been completely anticipated in his invention, our drawing showing the mirror hinged at the bottom the same as his. See vol. xiv., page 410.—ED.]

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
November 25 ...	North Middlesex Club	Jubilee Hall, Hornsey-road.

" 28 ...	Oldham	The Lyceum, Union-st., Oldham.
" 28 ...	London and Provincial	Masons Hall Tavern, Basinghall-st.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 14.—Mr. A. L. Henderson in the chair.

THE CHAIRMAN showed a large collection of photographs which he had gathered during a recent journey to the Antipodes. They were principally views taken in New Zealand, but included some other specimens, notably from Malta and Ceylon, and a large panorama of Sydney Harbour. Amongst the New Zealand photographs were a considerable number, both of portraits and views, by Morria, of Dunedin, of whose work in both departments the Chairman spoke very highly—and the work shown supported that good opinion. Amongst other photographers in New Zealand Mr. Frost was mentioned, a photographer formerly well known in this country in connexion particularly with photo-mechanical work. A very fine portrait of the Chairman, by Frost, was passed round with others. The photograph referred to last week as amongst the objects of interest from New Zealand, having some colour on the cheeks said to have been produced naturally, was shown. It was from the studio of Mr. Paul, of Dunedin, and was a *carte* print on bromide paper, with no trace of colour except a red tint on the cheeks, about the same amount of colour that was commonly put upon glass positives of the cheaper class in the early collodion days.

The opinion was generally expressed that the colouring had been done by hand, and it was proposed to submit the print to examination and test, and report upon it at another meeting. Other photographs of interest were some portrait groups taken by Frost by electric light, and some landscapes by Wheeler; one particularly noticeable amongst these was a view of Mount Cook.

THE CHAIRMAN then showed a negative with a large insensitive strip, which was attributed to some action proceeding from a new piece of wood that had been placed as a stop on the inside of the shutter. A further experience of the ill-effect of leaving plates in some shutters was mentioned. The shutters last referred to were some which had previously had an injurious effect on plates left in them, and therefore they had been allowed to dry for some months and then were treated with paraffin. Plates left in them since this treatment had been found to become insensitive.

Mr. J. B. B. WELLINGTON suggested that a clear space in one of the photographs might be due to the intervention of some part of the vessel on the deck of which the camera had been placed.

Mr. A. HADDON thought the Chairman's experience pointed to some emanation from the paraffin as having acted injuriously upon the plates.

THE CHAIRMAN showed a carbon print upon opal glass that had been made some years since. On washing it under a tap recently, the lighter half tones had come away from the support.

Mr. A. COWAN suggested that the separation might be due to gum used with the retouching colour, which, when dry, contracted and partly loosened the thin film underneath.

The thanks of the meeting having been tendered to Mr. Henderson for bringing the collection of pictures, the usual winter monthly lantern slide display took place. Slides were shown by Messrs. Teape, Wellington, Hastings, Kellow, Park, Freshwater, Hindley, and Cowan. Those by the last-named member were in illustration of the difference of results obtained by variations of the developer with a given make of plate, the same transparencies being used that had been shown at the previous meeting. The general opinion of the members on seeing the slides in the lantern was the same as that previously expressed on seeing the transparencies,—that on the whole none were better than those which had been developed with pyro bromide and ammonia, without sulphite, although the addition of bisulphite to the fixing solution had a slight clearing action which, for lantern slides, was thought beneficial. Another very successful series was that developed with eikonogen, the influence of increasing quantities of bromide in giving density was very evident.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

On the 15th instant the Committee were again engaged in considering the alteration of the rules of the Association, and made fair progress.

Mr. J. D. O'Connor was elected a member of the Committee.

CAMERA CLUB.

On Thursday, November 14, Major J. F. NOTT gave an address on *Films*, accompanied by a demonstration. Mr. F. Machell Smith occupied the chair.

Major Nott described the ordinary processes in the working of stripping films, and, in addition to his practical demonstration of these manipulations, he showed before the meeting some effectual methods for correcting and remedying faults which might be committed in some parts of the process.

Some surprise was experienced by those at the meeting at finding that Major Nott used neither rubber solution nor collodion, but simply squeezed the washed negative straight upon plain glass plates. An opinion was expressed that as this could be done successfully the greatest objection to the use of

stripping films was removed, and it was thought that the fact ought to be intimated in the working instructions sent out with the films.

Mr. DAVISON then showed examples of negatives upon stripped films, Vergara (Froelmann) films, and upon Allen & Rowell's cut celluloid films. He also exhibited the results of a few test exposures on some of the new rollable celluloid films about to be introduced by the Eastman Company, and described their behaviour in the roller slide, and in development, and the after processes. He found that the pieces when cut off the thin celluloid lay flat in development, and that by treatment with glycerine and water (or without any special treatment if pinned up at the four corners to dry) the pieces remained flat on drying.

Prints from some of the negatives were handed round.

A lively discussion took place.

Thursday, November 28, will be devoted to the lantern.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

NOVEMBER 11.—Mr. J. Humphries (President) in the chair.

Mr. D. P. RODGERS introduced the subject of *Hand Cameras*.

The following firms responded by sending representatives with specimens as manufactured by themselves:—Messrs. Mawson & Swan, Marion, Watson, Platinotype Company, Robinson, Photographic Stores, Shew, and Fallowfield exhibited their respective cameras of this class.

Next meeting, November 25, Mr. F. W. Hart will demonstrate his flash light.

UNIVERSITY COLLEGE PHOTOGRAPHIC SOCIETY.

THE first meeting of the Session 1889-90 was held in the Chemical Library on Tuesday, November 12. This was an informal reunion of members and their friends.

Messrs. Watson exhibited their detective camera and some recent models of half and whole-plate apparatus.

Mr. H. Park showed a whole-plate Victoria camera and Ashford's patent stand.

The next meeting will be held in the Chemical Library on Tuesday, November 26, at five p.m. Discussion on *Detective Cameras*.

HACKNEY PHOTOGRAPHIC SOCIETY.

NOVEMBER 14.—Mr. J. Hubert in the chair.

Five new members were elected.

Dr. KIBLER communicated to the Society the results of one of his investigations relating to a method of toning with the ordinary gold bath, not completing the process, but, instead, transferring the prints when still brown into the fixing bath, to which was added acetate of lead, causing a beautiful grey tone to the avoidance of rusty prints.

Discussion on this was postponed.

Mr. BERT ACRES read a paper upon *Colour-sensitive Plates*. After a few introductory remarks on the failure of ordinary plates to render incorrect values, the colours as seen in nature, and the consequent great loss of beauty in photographs from this cause, he went on to enumerate a few of the attempts of several scientists to discover some process which would correct this the greatest drawback to artistic photography. He then gave a brief outline of the discovery made by Waterhouse, that an ordinary collodion wet plate treated with eosine became strongly sensitive to yellow and orange, and the further development of this discovery by Taillor, of Paris, who applied it to the modern gelatine dry-plate process, by which he was able to prepare plates by the now well-known emulsified bromide of silver emulsion process, thus doing away with the necessity for dyeing plates, as plates treated with dyes soon became spoiled, whereas when the plates were prepared by this emulsion process they would keep as well as ordinary plates. One of the most important features of the paper was a very spirited attack on the use of the yellow screen. It was pointed out that, with the exception of copying paintings and in taking outdoor views in misty weather, the yellow screen was seldom or never required, the use of a yellow screen in landscape work under ordinary conditions spoiling the atmospheric effect in the resulting photograph, as it made the distant objects appear too near, thus destroying one of the principal charms of English landscapes. He then showed some silver prints and negatives of views in North Wales, taken a couple of weeks ago, on ordinary and on isochromatic plates, without a yellow screen, from the same point of view, at the same time, and under exactly the same conditions—the difference between the two processes being very strongly marked, for while the ordinary plate rendered the yellows, browns, and greens, of one uniform tint, the colour-sensitive plate rendered each in their proper values as seen by the human eye. He attributed the false impression that every colour-sensitive plate required the use of a yellow screen to the writings of Dr. Vogel, whose azaline plates were so slightly sensitive to yellow that unless a yellow screen was used no appreciable difference was obtained, whereas with a truly isochromatic plate the screen was a positive drawback. Continuing, he gave a few hints on manipulation, severely condemning the ridiculously small lamps that are frequently used for development, as, provided that the quality of the light was safe, a greater quantity was not likely to do any damage. He preferred pyro-ammonia for development, and recommended that in cases of under-exposure the developer should be further diluted, instead of the usual plan of adding ammonia.

Lantern slides from the ordinary and isochromatic plates were then shown on the screen, and whilst those from the ordinary plates were considered to be excellent, those from the colour-sensitive plates were pronounced to be better.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

NOVEMBER 14.—Mr. B. KARLSESE (Vice-President) in the chair.

Messrs. F. A. Compton, T. Walter Jones, and A. Roberts were elected as members.

The CHAIRMAN gave notice that all nominations of members to act on the Council for the ensuing year must be handed in that evening.

Mr. E. C. MIDDLETON read his paper on *Hints*, which proved instructive and valuable alike both for beginners and those farther advanced in photography. On October 25 the Lantern Committee gave a display of the American slides, per favour of the Camera Club.

The annual meeting of the Society will be held on the 28th instant.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

NOVEMBER 13.—The President (Mr. George Bankart) in the chair.

One member was elected.

Mr. THOMAS SCOTTON (Derby) then delivered a lecture on *Photographic Processes for Copying Line Drawings*. After having described the processes in detail, Mr. Scotton gave practical examples, by developing before the meeting a specimen print of each, accompanying each demonstration with a running fire of useful commentary.

IPSWICH PHOTOGRAPHIC SOCIETY.

NOVEMBER 14.—There was an exhibition of the *Illustrated Boston* slides. The lecture was read by Mr. FRANK WOOLNUGH. At the close Mr. Woolnough warmly commended the idea of the Boston Society, and suggested that their own members should undertake a similar enterprise in regard to the old town of Ipswich and its surroundings.

This matter will be brought before the Committee for consideration.

During the evening the prizes offered by Mr. J. C. Wiggin for the best six negatives taken during the summer excursions were awarded to Messrs. E. R. Pringle and R. Cash.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 7.—Mr. Wm. Lang, jun., F.C.S. (President), in the chair.

The following gentlemen were elected members of the Association:—Messrs. Edmund J. Nulls, D.Sc., F.R.S., R. C. Platt (Airdrie), Alex. Scott, John Morison, jun., James More, William Murdoch.

The office bearers for Session 1889-90 were afterwards appointed as follows:—President: Mr. William Lang, jun., F.C.S.—Vice-Presidents: Messrs. William Brown and William McLennan.—Council: Messrs. John Annan, William Jenkiss, W. J. McIlwrick, A. Maclear, George Mason, A. Watson.—Treasurer: Mr. George Bell.—Secretary: Mr. J. Craig Annan.

The PRESIDENT then read a paper entitled *Some Memorials of Daguerre* [see page 755], which was illustrated by lantern transparencies specially prepared.

Two volumes of cyanotype impressions, produced in 1859 by an unknown lady amateur, and which had belonged to the late Robert Hunt, F.R.S., were afterwards shown to the members.

Mr. Frieae Greene's opal cards next occupied the attention of the Society, and the meeting ended with a lantern exhibition of slides, the work of some of the members.

Correspondence.

Correspondents should never write on both sides of the paper.

PRICES OF DRY PLATES.

To the Editor.

SIR,—There are many inequalities and curious discrepancies in the prices charged by manufacturers of dry plates for the different sizes and various rapidities and thicknesses of films. The following tables give a few instances, to which, I should imagine, it is only necessary to call the attention of the manufacturers to secure a prompt rectification.

Plates.	Area.	Prices on same ratio as 1 plates.	Makers' prices.	Increase.
	Square Inches.	s. d.	s. d.	
4½ × 3½	13½	—	1 0	
8½ × 6½	55½ = 13½ × 4	4 0	4 3	6½ per cent.
15 × 12	180 = 13½ × 13½	13 0	18 0	38½ "
30 × 21	720 = 13½ × 58½	52 0	90 0	73 "

The makers endeavour, I believe, to justify these increased prices for large plates by asserting that the greater proportional charge is to cover (1) greater loss on broken and spoiled plates, and (2) increased cost of large glass. These points seem to me, however, to be more than balanced by (1) smaller cost of labour, as it obviously occupies less time to handle twelve plates 30 × 24, or 15 × 12, than 625 or 156 quarter-plates (this applies to all the operations, such as cutting and cleaning glass, coating, drying, and packing plates), and (2) diminished cost of cardboard boxes and packing papers.

Plates.	Prices: Pall Mall Extra Rapid, & Ilford Slow.	Ilford Extra Rapid.	Increase.	Pall Mall Thickly Coated.	Increase.
	s. d.	s. d.		s. d.	
4½ × 3½	1 0	1 6	50 per cent.	1 6	50 per cent.
7½ × 5	3 5	5 3	51 "	4 6	28½ "
8½ × 6½	4 3	6 6	50 "	6 6	50 "
15 × 12	18 0	28 0	56 "	23 0	28 "

It is curious that whilst the enhanced cost, in consequence of the

increased quantity of silver bromide, is estimated alike by both manufacturers in the quarter and half-plate sizes, in the 15 x 12 size they vary as one to two. I am convinced that a reduction in the cost of the larger plates would tend, by increasing their use, to greatly benefit the receipts and profits of the manufacturers.—I am, yours, &c.,
Penzance, November 18, 1889. W. HERBERT PERCY.

PROOFS AND RESITTINGS.

To the Editor.

SIR,—The inquiry of your provincial correspondent as to the recognised practice of first-class London houses, with regard to the number of proofs submitted and resittings, cannot, I fear, receive a very satisfactory answer, for, as you remark, the growing tendency is to submit a number of proofs out of proportion to the order given; and very probably a resitting for some trifling objection or caprice, so well known to photographers, follows upon his extra endeavours to obtain success. It is a subject so important to the profession throughout, that I have often thought that, if possible, it should be discussed and formulated into some definite rules, to be used with discretion by each individual firm; but it is evident that unless there is unity of action throughout the profession, it is quite hopeless to alter the existing state of things. If that could be brought about, I, for one, should be devoutly thankful.—I am, yours, &c.,
63A, Baker-street, Portman-square, W. WILLIAM GROVE.

To the Editor.

SIR,—Concerning the number of proofs to be submitted for approval, my experience is that two are enough, for this simple reason: If the dress, as to fit, style, or other objections, does not please the party, if you were to take fifty, they would all be condemned. I have found this out years since. I found, in practice, this answers perfectly: If they are found fault with, it is easy to take two others as a re-sit.

I have an idea it is possible to make oneself too cheap.—I am, yours, &c.,
Cardiff, November 20, 1889. AN ARTIST.

THE FUNCTION OF THE PHOTOGRAPHIC SOCIETY'S COUNCIL.

To the Editor.

SIR,—Early in the present year the Photographic Club appointed a Committee to consider the desirability of adopting a uniform system of weights and measures for writing photographic formulae, and in due course this Committee issued a Report recommending that a certain course be adopted. This Report was sent to each of the recognised photographic societies with a letter to the Secretary, distinctly stating that it was for communication to his Society, and asking for its support in obtaining the adoption of its principles. The letter and report were duly received by the Hon. Secretary of the Photographic Society of Great Britain; but, with a want of courtesy to the Photographic Club, which it is to be hoped was not intentional, the matter has not been brought before the Society, except that in the next number of the journal of the Society the letter and Report were printed, together with an intimation that the Council had discussed the matter, and had replied that the Society would co-operate in getting the proposed system adopted.

As a member of the Society, and one much interested in the question involved, I felt that such an important subject deserved serious consideration before the Society should be pledged to any definite course, and I considered that the decision should not be left to that small number of the members who are chosen, presumably for their business abilities, and not for their scientific knowledge, to conduct its affairs. The following letter was, therefore, addressed by me to the Hon. Secretary:—

DEAR SIR,—In the June number of the journal there is published a letter addressed to you by the Hon. Secretary of the Photographic Club enclosing a Report of a Sub-Committee of that Club for communication to your Society. Up to the present the Society has had no opportunity of expressing an opinion upon the question raised, but I find it stated at the foot of the Report that the Council have considered the question and have replied in the name of the Society.

I regret it should be necessary to point out that the Council, in discussing and adjudicating upon a purely scientific question, such as that referred to the Society in this case, is not only exceeding its function, which is to manage the business of the Society, but is robbing the ordinary members of what is most distinctly their right of expressing an opinion upon any photographic matter brought to the Society for discussion. At the same time, there is no doubt that it would be quite competent for the Society, as a body, to repudiate the dictum of the Council upon such a question.—I am, yours, &c., A. MACKIE.

To this I have received a reply that "the Council do not see their way to taking any further steps with regard to the question."

Having thus failed in bringing the matter before my fellow-members by an appeal to the Council through the proper channel, I am reluctantly compelled to state my case in the present manner.

It is much to be regretted that the reform in the laws of the Society has not resulted in a corresponding improvement in the spirit of its government, and that the present Council should have chosen to follow the worst traditions of its predecessors. Under past misrule the representative character of the Society long since ceased to be acknowledged;

but a time has come when, under vigorous and conscientious administration, there is hope that its prestige might be restored. It would be a thousand pities if the opportunity were neglected.—I am, yours, &c.,
10, Queen's-road, N.W., November 18, 1889. A. MACKIE.

[Having a vivid recollection of the revolution, jeopardising the very existence of the Society, that arose from cognate causes several years ago, we feel concerned at any member of the Society thinking that the Council oversteps its functions in deciding upon matters which rightly ought to be brought before the members generally.—ED.]

EXHIBITION MATTERS.

To the Editor.

SIR,—I have, like "An Old Medallist," and "Wyrall," for a considerable number of years past looked forward to the annual trip to town to visit the big Society's Show, to see the work of exhibitors who are recognised as masters in our art. Alas! what has become of them? There are certainly a few left whom the bronze bait appears to attract, but where are the majority? Have they received sufficient honours from the Society, or are they lamenting over damaged frames, or does their work get better shown and their frames get better treated at the provincial exhibitions? Echo seems to favour the latter.

This, doubtless, accounts for the grand shows of photography made at many of the provincial exhibitions within these last three or four years, and the magnificent collection now annually brought together at the Crystal Palace, where platinotype, carbon, and silver can be seen to advantage, which cannot be done when work from all three of these processes is huddled and mixed together indiscriminately in one small room, with the result that it is painful to look upon, and reminds one of a cheap draper's shop where contrasts are great—reds and blues being mixed together with startling effect. If platinotype, carbon, and silver are to be shown together in one small room, let them be shown fairly and advantageously to each, and not be mixed together like a mosaic or fancy tile pavement. And why should the names and addresses of some exhibitors be allowed to appear upon their works year after year, and yet the rules sent out by the Society forbid such practices? I myself have gone to the trouble of remounting pictures which have had my name and address upon them, fearing they might be rejected, and I have been somewhat surprised to find that by putting a stroke of the pen through the address, or pasting a piece of transparent paper over same, I might have saved myself trouble and expense, and have got an advertisement for my wall-space money.

I have exhibited annually for about fourteen years until this year, and have been skied, floored, and on the line, and still I am discontented, and, like "An Old Medallist," and "Wyrall," think that the time has come for a new organization and a new Exhibition, when I think that our old friends who are now so conspicuous by their absence would again put on their war paint and come to the front. Trusting that some of them more able with the pen than myself will take it up, and let us know wherefore their absence—I am, yours, &c., OLD MEDALLIST No. 2.

To the Editor.

SIR,—During the past few days I have had an opportunity of talking to several of the foremost men in the profession, both London and provincial. A few of the replies to my query, as to why they had ceased to exhibit, may be interesting.

A. "No, thank you; no more for me. The game was not worth the candle. *Pall Mall* packing has cost me dear."

B. "Yes, I sent about half a dozen important pictures this year, but they were distributed all over the place, and instead of being a good show they were no use to me at all. I shall not trouble to send again."

C. "Last time I sent I had to hunt up my pictures from Middlesex Hospital way. What they were supposed to be suffering from I was never told; but that year — was competing, so I suppose mine were carefully not shown."

D. "Yes, I was offended, and had, I think, cause. I had to listen last time to one of my very best works being pulled to pieces by one of the officials at the very top of his by no means musical voice, to a full room. Of course, I could not reply, however absurd his strictures. I should have liked to have had him outside for a few minutes!"

E. "See no use to showing my style and methods, to be copied by the fellow 'over the way.'"

If the above, which are genuine expressions of opinion, are of any use, why "there they are."—I am, yours, &c., AN OLD MEDALLIST.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—My attention having been arrested by a letter in the columns of your JOURNAL, by Mr. Bart. Rous, condemning in the most emphatic manner all the works of Mr. Robinson exhibited at the Camera Club, I am tempted to make a few remarks upon the subject.

In the first place, the letter is assuredly a most uncalled-for attack upon the work of a professional photographer, who, as the pioneer of combination printing and picture making in photography, was one of the first to raise it from a mere mechanism to the realms of art, and who for

thirty years has laboured earnestly and conscientiously in the same direction both with camera and pen. That his labours have met with the success they deserved is testified by the number of gold medals awarded him in all the capitals of Europe, and by the fact that there is scarcely a place in the world in which photography is practised that his name is not known.

Mr. Rous condemns *in toto* the combinations as unnatural and impossible, and the figures as dressed-up models; but this is an assertion so evidently unjustified by facts, that it may be passed over without comment.

Considering the great number of works Mr. Robinson has produced, he would be more than human had he never erred, but there are many examples which are in every way as much entitled to be called works of art, as any to be found on the walls of our art exhibitions.

Mr. Rous tells us, what indeed we know, that a photograph must be also a picture or it can never be worthy to be called a work of art. But what does he consider constitutes a picture? If there are none among Mr. Robinson's collection, where is he going to find them? This is a slap at professional productions *en masse*.

But who is this Daniel come to judgment? . . . As professional men we have not the slightest objection to Mr. Rous' attacks, but in sheer justice we hope he will show us some of his own work at the Society's Exhibition next year, when we shall be able to judge for ourselves whether his criticisms are worth consideration or not.—I am, yours, &c.,

Torquay, November 18, 1889.

W. DURRANT.

To the Editor.

SIR,—“A Member of the Camera Club,” who uses my name so freely, while withholding his own, is quite welcome to his opinion of my photography. He probably admires it, as much as I do myself, as photography. Let me remind him that “Mr. Rous's work” was not the subject of my letter, but Mr. H. P. Robinson's work. My work, being worthless, would not lessen the worthlessness of any one else's.—I am, yours, &c.,

The Arts Club.

BART. ROUS.

EXHIBITION OF REJLANDER'S PHOTOGRAPHS.

To the Editor.

SIR,—Would you kindly allow me to state that the Committee of the Camera Club proposes that the next Exhibition in the Club Rooms, after Mr. H. P. Robinson's is closed, should consist of a collection of pictures by Mr. O. G. Rejlander? To ensure a full and representative number of his pictures being brought together, I should be much obliged to any of your readers who possess prints by Rejlander, and would be willing to lend them for exhibition, would kindly communicate with me at the Club.—I am, yours, &c.,

GEORGE DAVISON, Hon. Sec.

Camera Club, 21, Bedford-street, W.C., November 18, 1889.

AMATEURISM.

To the Editor.

SIR,—This subject reminds me of Sir J. D. Lenton's picture, *The Banquet*, in which a monkey is nicely posed on the garden wall while the guests dance to their hearts' content. Now may I suggest a way out of the difficulty?—that the following chemicals be heavily taxed: pyrogallol, neutral oxalate of potash, quinol, and eikonogen. This will raise the price of photographs and place photography in the good old position it occupied when the wet process was to the front.—I am, yours, &c.,

23, Cattell-road, Birmingham.

H. VICTOR PAGE.

To the Editor.

SIR,—I, too, wish to place a stone on the cairn of this discussion, “Professional Amateur,” and claim the privilege of your columns in that I have been engaged in the art, more or less, from the early silver-plate days—now, alas! some forty years ago—and as a subscriber (in the stereotyped phrase) all through from the birth of your parent journal the *Liverpool*; thus long before your boasting professionals existed, or, at least, put forth such pretentious claims as they now do. Why, your professional is little more than a mere machine, willing and eager, I grant you, at all times to gather a wrinkle or receive a lesson from the so-called amateur. In fact, the greater number of your successful “professionals” have only had the discernment and wisdom to gather round them men who have mastered detail; and these professionals could not, individually, for their very life, do what many an amateur could. How could they? They have to live. Where would your *JOURNAL* be, and other similar publications, and, indeed, the whole art itself and its various ingenious and clever craftsmen who now so lavishly and honestly minister to its wants, if it were left to professionals? LET THESE MEN THEN BE SILENT. They prosper on the patient labour of amateurs, who, in many cases, take to the art as a relaxation from other and, possibly, less remunerative pursuits.—I am, yours, &c.,

Partick, November 16, 1889.

WM. CALDWELL.

To the Editor.

SIR,—Why so many words about the name “Amateur?” All workers in photography are supposed to be lovers of it. In it there are evidently

three classes of workers. To each class give a distinct name, and be done with it.

I suggest that we call the first class “Gentlemen Amateurs,” gentlemen who work at it for pleasure and enjoyment solely, and from whom we have received much, and from whom we expect to receive much more. Next, we have—for want of a better name I shall call the “Professional Amateurs,” or “Amateur Professionals,”—men who work at it for pleasure, but also with an eye open for profit.

And, lastly, we have the “Professionals proper,” men who make it their daily business, or, as Mr. Barnes names it, “their bread and butter.”

All these three classes are equally honest and legitimate; and, to use the language of another of your correspondents, “it is presumption and impudence in any man to find fault with his neighbour.” Every worker, as a sane man, has entered the class best suited to his own interests, and at any time he has perfect liberty, should he repent of his choice, to leave it and to enter the one he likes better. There is, therefore, no cause for ill-feeling to exist in any class against its neighbour; and the man who entertains any, is not only an enemy to his class, but an enemy to mankind generally, and the sooner he is stamped out the better for society.—I am, yours, &c.,

November 18.

F.

EIKONOGEN.

To the Editor.

SIR,—This new agent is having anything but a fair and common-sense trial. I would urge those who try it to stick to the inventor's formulae for some time, and leave their experiments till afterwards.

A great many of our clever men complain about their solutions going black; if they will take care that the sulphite and carbonate of sodas are thoroughly dissolved before adding the eikonogen, they will find this discolouration disappear.

For myself, I dissolve the sodas, leave them for twelve hours or more, and then add the “kono,” using distilled water only. I have a one solution developer made up according to Dr. Andresen's formula, which is now three months old, and it is still as clear as crystal.—I am, yours, &c.,

HENRY L. BENWELL.

Folly Bridge, Oxford, November 16, 1889.

TONING DIFFICULTIES.

To the Editor.

SIR,—In some of your late numbers you have referred to the numerous appeals made to you by amateurs concerning their difficulties in toning. One, in particular, of your correspondents much excited my sympathy by his inability to escape from the dirty, reddish-brown tone. Having myself “been there,” I feel tempted—with your kind permission, and, of course, thoroughly endorsing your remarks as to the necessity for strong negatives, and so forth—to offer a suggestion, which, I venture to believe, may benefit. Judging by my own experience, I should say that the average amateur, with his comparatively few prints and small toning bath, errs if he acts upon the rule of one grain of gold for each sheet of paper to be toned. Given good negatives, good prints, and proper care, should the tone still be a failure, I would suggest *more gold*. I enclose two or three half-plate prints of flowers to testify as to my own results in tone. I claim nothing remarkable, but that by using “more gold” I have certainly escaped from “the dirty reddish-brown.” I use soda—no sulphite—for developing, and for printing purposes prefer a “greenery-gallery” negative.

I use preferably the lime bath as given by Captain Abney—the No. 1 in his “Instructions;” I somewhat lessen the quantity of lime. I use Messrs. Watson's single albumenised sensitive paper.—I am, yours, &c.,

Bournemouth, November 18, 1889.

J. G. R.

[The tone of the prints is very rich.—Ed.]

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as “anything useful” will therefore understand the reason of their non-appearance.

Safety bicycle, balls all over, will be exchanged for cabinet or larger lens.—Address: C. BANYARD, Leaton, Suffolk.

Will exchange four well-painted 12×10's (in oil) for an old whole-plate or 10×8 camera, complete.—Address, GRIFF, 38, East-street, Leicester.

Silver English lever, with centre second, in exchange for half-plate portrait lens, camera, and stand.—Address, J. KEVAN, 11, Rodney-street, Liverpool.

I will exchange violin and case for half-plate rectilinear lens by good maker, or for good half and whole-size plates.—Address, B. WOODROW, Park-street, Toweester, Northamptonshire.

I will exchange stereoscopic mahogany camera, with lenses, five slides, and tripod, for half-plate bellows camera.—Address, W. CHURCHILL, jun., Photographer, East-street, Wareham, Dorset.

I will exchange a pair of Newton's mahogany lanterns (four-inch condensers), in case, for a cabinet portrait lens or rapid symmetrical.—Address, W. T. WHETTER, Photographer, Villiers-road, Bristol.

Will exchange enlarging lantern, five-inch condenser, and blow-through jet, for Humber or Salvo tricycle. Each article to be sent carriage paid.—Address, G. H. DENMOSE, Chemist, Downton, Wilts.

Universal studio camera, 8½x6½, two slides, and Grubb's 2n lens; portable bellows camera, 10x8, with two double and one single slides and doublet lens; and large box of oil colours; to exchange. Wanted, 12x10 portable bellows camera (Dallmeyer's 3n or 3a lens).—Address, HEWITT, 80, St. Thomas's-street, Weymouth.

Answers to Correspondents.

* Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

W. H. D.—There is no relationship between the two.

X. X.—It is not correct that every one at the French Exhibition got a medal, as we know several that did not.

INQUIRER.—There will be more than one article on the subject in the forthcoming ALMANAC. Better wait for that.

A. S.—An ordinary portrait lens works quicker than the others named, and, hence, would be more suitable for children's portraits.

W. Wm's.—Read the articles now appearing in the JOURNAL by Mr. Redmond Barrett. These will give you the required information.

A CORRECTION.—Mr. Alfred Green directs our attention to an arithmetical error in an article on lunar photography, in which 156 is printed instead of 216.

DEVELOPER.—If the solution is only discoloured to the extent described, its working properties will, practically, not be interfered with. Why not have tried the solution before writing?

H. E. M. (Sea View).—Get some one to give you a few lessons in retouching, or study the series of articles on the subject by Mr. Redmond Barrett which appeared in our volume for 1886.

ALEX. STEVENSON.—The recent presentation prints of the Art Union are all copyright, therefore to pirate them subjects the pirate to the penalties. His being a subscriber to the Union makes no difference.

A. H. C.—The only way to arrive at a correct exposure is to make a trial—using different portions of the plate different exposures. "Ordinary gas burners about four feet away" is no data upon which to give an opinion.

BEGINNER.—Your neighbour cannot prevent the building; but it is possible that plans will have to be submitted to the local authorities. Better consult the surveyor of the district. As all the houses are newly erected, there can be no ancient lights to be interfered with.

J. W.—In copying a painting with orthochromatic plates, when the light is somewhat yellow a paler screen should be used than when the light is very clear and white. In copying, when the light is very yellow the colour screen may sometimes advantageously be dispensed with.

NEMO.—Send an example of the trouble. From the details to hand, we strongly suspect that the evil arises from light in the enlarging room. See that no white light gains admittance when the light is temporarily stopped out. A crack in the shutter would fully account for the difficulty.

A. WESTON.—Why not coat the back of the negative with matt varnish and then scrape it away in the highest lights? If the effect obtained by this treatment is not sufficient, stomp a little plumbago on the deepest shadows. By this means harmonious prints may often be obtained from harsh negatives.

W. PERL.—The fact of the lens bearing no name does not indicate that it is necessarily a bad one. There are many excellent lenses in use which have no maker's name upon them. The name of a maker of reputation is a guarantee of quality. In purchasing a second-hand lens without a name, a trial should be allowed.

EGYPTIAN asks:—"If I enlarge a quarter-plate negative to whole-plate, how many diameters enlargement would that be called?"—Two diameters, of course. A foot rule shows that a whole-plate measures eight and a half inches, and a quarter-plate four and a quarter inches in their longest dimensions. The enlargement would be four times linear.

ARCHER says the plates he is now using, though exceedingly good in other respects, all have a "metallic or iridescent appearance," extending for half an inch or more round the margins, with no detail at all there. He asks if there is any means of avoiding the evil.—The fault is with the plates; they have evidently been made for a long time. There is no remedy but fresh plates.

B. GEDGE.—The half-plate "rapid" will certainly answer better for enlarging with than the quarter-plate portrait lens; but your camera will not be long enough to enable you to enlarge from five by four inches up to ten by eight with that lens. The best plan will be to have a cone made to fit the front of the camera so as to lengthen it about twelve inches. Make the enlargements direct on bromide paper. If you make an enlarged negative, a transparency must first be produced.

GEORGE B. ANDREWS.—There is no restriction whatever in photographing the buildings in Ghent, Bruges, or any of the other Belgian cities. Also, there is no difficulty in taking dry plates with you, the Custom House officials knowing all about photographic requirements, and being civil and obliging. We recommend you to take both wide-angle lenses for the buildings, some of which are very tall, and quick-acting lenses for street scenes, which will amply repay any trouble or expense.

G. WILMOT.—So far as we are aware, there are no dry plates prepared for stripping the films from made in this country, though they are articles of commerce both on the Continent and in America. Plener's method of stripping with hydrochloric acid is, as you say, a disagreeable one; still, it is the best in practice. If celluloid films are too thick, why not try the Eastman stripping films? They are well adapted for reversed negatives. Messrs. Horne & Thornthwaite, Strand, supply reversing mirrors.

B. B. B. writes, complaining that he recently purchased three dozen dry plates, 7½x5 size, and each packet contained one or more broken ones, and several others scratched by the fragments of glass. He wishes to know if he has any means of recompense, as both the seller and the maker deny their liability. Our correspondent says it is exceedingly annoying when away from home to find, on opening a dozen packet, two or three broken plates, and as many more useless through scratches.—We are quite in accord with him.

J. W. M. requires the following information:—"Can you oblige me by suggesting how I can overcome the following difficulty?—I have to prepare a large number of sheets of tracing cloth for the iron process, positive from positive, but cannot prevent the liquid from going through, so that when printed and developed, it always leaves a black back. I have tried resin in turps and alcohol, rubbed in, also liquid indiarubber, arrowroot, and such like—two coatings—but cannot get over it. There must be some method, although I am ignorant of it; perhaps in the place of tracing cloth there is some other finely woven cotton used?"—Perhaps some of our readers can enlighten our correspondent.

TOP LIGHT writes:—"Your advice as to the following will oblige. I have taken a house in which is a large room with a good side, but no top light; now, I wish to convert this into a studio to do portraiture and copying; what can be done to the top and reverse side so as to get an all-round light? Can you advise any kind of reflectors for this purpose? Is a top light really necessary? The room is about fifteen feet by ten feet, with side light two feet from each end and about two feet from the floor. I think by contriving a bit I can make this room to turn out decent work."—Very good portraits can be taken in a room such as that described. If the side light be high it becomes practically a top light. Our correspondent does not say the height, or we could better advise. However, all that can be done is to employ reflectors—either white or pale blue—to soften the shadows. Under such conditions as these it will be found better to use large reflectors placed at a distance than small ones closer to the subject.

PHOTOGRAPHIC CLUB.—Wednesday, November 27.—The monthly lantern meeting.

PHOTOGRAPHIC SCRAPS.—This monthly (November issue) issued by the Britannia Works Company, is full of variety as usual. It makes nice desultory reading.

EXHIBITION OF ANIMAL PAINTINGS.—The committee of the Animals' Institute will open their Winter Exhibition of Animal Paintings on December 7, when the Institute medals will be presented for the encouragement of animal artists. All exhibits must be sent before or on December 1, to 9, Kinnerton-street, Belgrave-square.

TRANSPARENCY FRAMES.—Messrs. Mawson & Swan have submitted specimens of a simple transparency frame they are introducing. It consists of a half-round metallic band, which is bent so as to surround the transparency, with corner pieces to prevent its falling out. It is suspended by a chain affixed to the two upper corners.

CRYSTALLISED EIKONOGEX.—We have received from Messrs. Marion & Co. a sample of a new make of Dr. M. Andresen's Eikonogen, which presents a different appearance from any we have previously seen, being in the form of large crystals, having a slightly yellowish tinge. Approved formulae for its use as a developer accompany each bottle. Great things may be anticipated by the introduction of such a fine preparation of this useful developing agent.

ROYTON.—A Photographic Exhibition, in aid of the Church restoration fund, Royton (near Oldham), will be held in the Town Hall, Royton, on February 5 to 20, 1890. Several medals are offered. Applications for space must be made not later than December 31, 1889. A small entrance-fee will be charged for pictures, a charge of five shillings being made to each exhibitor of apparatus. Address, Rev. Geo. Gibson, Royton (near Oldham), enclosing stamped envelope for reply.

MUYBRIDGE AT BATH.—On Monday, December 2, Mr. Muybridge is to give his celebrated lecture on *Animal Locomotion* in the Assembly Rooms, Bath, which, it is scarcely necessary to say, will be illustrated by his zoopraxiscope and a large series of instantaneous photographs. This lecture is to be under the auspices of the Mayor of Bath and the Presidents and Officers of all the local scientific and art societies, including the Bath Photographic Society. Every one interested in the possibilities and capabilities of photography ought to be present.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1543. VOL. XXXVI.—NOVEMBER 29, 1889.

POSITIVES ON CELLULOID.

It is not by any means an easy matter nowadays to hit upon any striking novelty in connexion with photography capable of taking and holding the popular fancy, and we are, therefore, surprised that no practical use has yet apparently been made of celluloid for positive purposes. The public at large is apt to tire of one particular style of picture; *toujours perdrix* is, metaphorically speaking, no more pleasant when applied to photographs than in the literal sense, and though silver prints have for so long a period held the premier position, there are not wanting signs that at last they are losing their firm hold on public favour. The rival claims of gelatino-bromide and platinum prints have begun to assert themselves, even outside the circle of those whose artistic instincts from the first led them to approve the chaste delicacy of the platinum proof; indeed, it only required the change of fashion, the necessary education to the cool tones and matt surface, to cause the public taste to extend in the new direction.

But, though platinotype and bromide prints have now become regularly recognised products of the professional studio, it is difficult in a practically business way to rouse any great amount of enthusiasm in their favour over and above the ordinary and normal. The vast well-to-do classes look upon it as a matter of duty to be photographed from time to time, but as to most people the ordeal is not a pleasant one—it is postponed as frequently and as far as possible, and nothing short of a decided novelty will electrify sitters into anything like enthusiasm.

Since the introduction of celluloid in extremely thin sheets in this country, a considerable demand has arisen for the films for negative work, and we have seen several very fine effects for decorative purposes in the form of transparencies both for framing and for ornamental glazing. The slightly roughed surface of the celluloid renders it eminently suitable for this class of work, the grain being finer and more delicate than the smoothest ground glass, while the details of the picture are as well thrown up as with a backing of greater density.

But it is not in the direction of transparencies that we consider celluloid has been neglected, but rather of positives to be viewed by reflected light, whether for framing or for album purposes. Opal pictures which, when artistically executed, far excel the best paper prints, both in delicacy of detail and richness of gradation, have long held a deservedly high position, and have commanded high prices when something out of the common or above the average of "an ordinary portrait" is required. But opal in every form is, at present, suffering from the effects of over-cheap production; the shop windows have been full for some time past of indifferently executed opals of any and every kind of subject, and for almost every possible

purpose, until the ordinary mortal has got sick of them, while the former patrons of the better class of opal have lost faith in it.

As a substitute for opal, we can imagine nothing better than the imitation ivory, several different kinds of which have been from time to time introduced, though none, we think, approaches celluloid in general good qualities. The colour, for one thing, is to the artistic eye far more pleasing than the cool tint of most opal glass; it is better suited to warm tones, though not one whit inferior to opal for cool greys or black. It is lighter, less bulky, less fragile than glass, and may be so used as to require no mounting either for framing or any other purpose.

The material we now refer to differs from the celluloid employed for negatives, both in thickness and translucency; an opaque white or cream-coloured pigment is combined with the celluloid, which gives it a certain degree of opacity, increasing, of course, with the thickness of the material, and this can be varied at will. We employed nearly ten years ago a sample made, we believe, by the British Xylonite Company, of Hoxton, which was upwards of one-sixteenth of an inch in thickness, though that now supplied by the English agents of the American manufacturers is only about a fourth of that thickness. One side is finished with an extremely fine polish, fully equal to ivory, and its resemblance to the latter is still further enhanced by a most natural and skilful imitation of the ivory grain. It is perfectly impervious to moisture, not liable to stain, and, in fact, in every way as convenient as glass; and why the makers of plates and films should have so far neglected so promising a novelty is a matter of surprise. Such films in the sensitive condition have been placed on the market, but apparently did not "take," so, perhaps, it may be the fault of the public after all.

Failing the possibility of obtaining the sensitised celluloid, it is not a difficult matter for the photographer himself to coat it with emulsion. The material is obtainable from the agents, whose address will be found in our columns, in sheets measuring 50 x 20 inches, costing 7s. or 8s., and as each sheet will cut up into about thirty cabinets it will be seen that the celluloid is cheaper than good opal glass.

Any good, slow emulsion will answer well for positives, but it is better that it should for the purpose contain a larger proportion of gelatine and less silver than is usual when a negative image is required. This gives a more transparent deposit, and adds to the depth and richness of gradation.

It will not be found convenient, working on a small scale, to coat the full-sized sheets, nor, indeed, anything much exceeding one-sixth of the dimensions, owing to the difficulty of getting the flexible material to be perfectly flat. We have tried a

variety of ways of securing this end, but find nothing more convenient than to squeegee the celluloid on to a sheet of plate glass previously coated with an adhesive material, such as india-rubber solution or one of the adhesive plasters obtainable at any chemists. A very thick mixture of gelatine and glycerine, similar to the well-known "graph" composition, answers well if the emulsion is not too hot when poured on, and we have even succeeded by simply wetting the glass before laying down the celluloid. What is required is simply to retain the sheet in contact with the glass until the emulsion has set, after which it may be stripped off and hung up to dry.

The size of the sheets coated will depend upon the sizes to which they are subsequently to be cut; it should not be too great, owing to the difficulty we have mentioned, nor too small, or extra time and labour will be wasted in coating. The cabinet size cuts rather awkwardly into 50×20 so as to use the material to best advantage, though for general purposes the dimensions are very convenient. Whatever size be selected, care should be taken to allow for cutting off bad edges, which are more liable to occur with celluloid than with glass.

The next point is the cleaning or preparing the surface to receive the emulsion, and this is a rather difficult task, owing to the apparent greasiness of the celluloid. The trouble is vastly lessened by slightly abrading the surface; but then, for some purposes, the beauty of the imitation ivory picture, especially in small sizes, lies in its fine, though unobtrusive polish. If a matt surface will answer, then the polish may be removed by friction with prepared chalk, made into a thin paste with alcohol; or, perhaps, a better plan is to pour plain methylated alcohol on and off a few times, when, upon setting it aside to dry, the surface will be found to have lost its fine finish. A little ether may be added to the alcohol to increase the matt effect.

When it is requisite to preserve the high polish, some other means must be adopted of causing the emulsion to take to the repellent surface. Similar precautions are frequently taken in conjunction with glass, such as applying a preliminary coating of such solutions as silicate of potash or sugar, and these might answer with celluloid, though we are not in favour of such applications. Polishing with powdered talc we have practised with success, though it occasionally fails; but to make assurance doubly sure it is better to follow up the latter treatment by giving a coating of plain gelatine solution containing 10 grains of gelatine, $\frac{1}{4}$ grain chrome alum, and $\frac{1}{2}$ drachm methylated alcohol to each ounce of water. This may be poured on to the levelled celluloid, or the latter may be floated on the gelatine, and the surplus in either case drained off without waiting for it to set. Before placing the coated sheet away to dry, examine it carefully to see that the gelatine has not run away from any portions; if it has, the bare portions must be rubbed with a piece of sponge dipped in the gelatine solution and the coating or floating repeated.

When the celluloid so prepared is dry, it is ready for coating with emulsion, which will then take readily to the surface and adhere perfectly. For coating, let the celluloid be laid down upon glass in the manner described, and then covered with emulsion just as if it were a glass plate only, the film and support being laid upon a levelled slab to set in the ordinary manner. When set quite hard, insert the point of a penknife between celluloid and glass, and the two will part readily, and the sensitive film may be hung up in the drying cupboard to dry.

In cutting up to size, a glass shape and a pair of long-bladed

scissors will prove more satisfactory than any form of cutting or trimming knife, owing to the thickness and toughness of the material; but undoubtedly the best way of reducing the sheets to standard and uniform size, where it is available, is the card or mount-cutting machine that now is to be found in many studios. This is at once expeditious and accurate, and nothing is so essential to neatness of finish or accuracy in cutting.

Collodion emulsion may be substituted for gelatine if preferred, but if applied to the bare celluloid will slightly lower the gloss, and at times tend to produce a slightly sunken appearance in the shadows. The preliminary coating of gelatine obviates this, thus retaining the full polish and giving brilliance and transparency to the image.

Pictures, whether portrait or landscape, should be printed under a mask, in order to provide a clear, white margin, except in the case of those of large size, which are better framed or mounted without margin. If protected by means of a suitable varnish, such pictures may be placed in albums or framed without glass, and exhibit little tendency to succumb to the ordinary wear and tear to which such things are subjected.

We repeat, in conclusion, our surprise that so little has been done in this kind of picture; but perhaps some of the plate-makers will, ere long, remedy the neglect by placing the coated celluloid for positives on the market.

PHOTOGRAPHING INTERIORS.

No. II.

LENSES and camera selected, the tripod claims an important share of attention, and, seeing that an exposure may range over many hours, sometimes even days, rigidity and steadiness are naturally, essential, conditions of construction. We know many old hands who have a very decided preference in this kind of work for the old-fashioned triangular top and ash tripod, made still in the same form in which it was known a quarter of a century ago. Where it can be used nothing can excel it; but it so often happens that the best standpoint for a particular view may be from some inconvenient corner, against an immoveable piece of furniture, off a flight of stairs, through a narrow aperture, or in one of the many awkward spots that those skilled in interiors are only too familiar with, that to use such a tripod is almost impossible. On these occasions, one capable of adjustment as regards the length of its legs is a *sine quâ non*. It is true that extemporised makeshifts can be employed, and with advantage; thus we have used a pair of library steps, and have not disdained the loan of a portable stand for a butler's tray, two of which, superposed, stood us in good stead on one particular occasion. A tripod selected, the first difficulty that is likely to present itself will be the slipping of its points upon the stone floor of church or public building, or the polished wood of a well-built mansion. To avoid this, either the legs must be tied, or, what is better, india-rubber or cork or other shoes provided to fit the metal points, and prevent the sliding away that will happen, though the utmost care be exercised in inserting them in the interstices between the tiles or other portions of the floor. But, again to extemporise an expedient, we must confess to a feeling really of partiality for one or two door-mats to subserve the purpose of slip-preventing. They are to be had in every house and every public building, and one for the front limb and another for those at the back form a foothold which cannot be excelled. Provided, let us add, that the points of the tripod are well

pressed down into the mats, for during an exposure of several hours we have known of blurring being produced by a slight sinking of the whole into the body of the semi-elastic surface of a good cocoa-fibre mat.

Slightly departing from the natural sequence of work in the actual process of taking an interior negative, we may here, so as to keep the more purely mechanical aspects of the case together, refer to the "focussing;" we mean the examination of the image and getting it into focus—a very slight matter to the inexperienced it may appear, but by no means so in reality. It is, in fact, so difficult at times, that we have placed a camera and plate ready focussed *in situ*, and used our judgment only as to its being in focus. The common difficulty is the necessity of working in a corner or some excessively cramped position, and finding, upon examining the ground glass, that there is apparently nothing to be seen owing to the absence of any strong light in the apartment to be photographed. Here it is that the absence of a tail-board or other projection under the chin will be appreciated. However, if the head is kept well covered with the cloth, the eyes will, in a few minutes, begin to perceive sufficient to enable a judgment to be formed as to how the subject generally falls upon the screen, though it will usually happen that some portions can only be calculated as occupying a certain position. It may be that the chief interest of the picture centres in some particularly dark piece of carving, be it wood or stone, and that this in particular must be in focus at all hazards. A white pocket-handkerchief waved about, close to its surface, by an assistant will aid in fixing its position, though occasions will arise when there is not light enough for even this expedient to succeed. The plan then is simply to light a wax match or taper, and let it be held at the salient points necessary to be examined; this will fix the position of the object, and permit a proper focus to be obtained. In our own practice, at sundry times, we have met instances where no other method was available.

The difficulty may arise, perhaps, that an essential portion of the view, although using the shortest focus lens possible, just extends beyond the edge of the plate, even when the body is compressed in the smallest possible space; when, in fact, that little extra space for retiring the camera is just what is needed to enable the whole of the subject to be embraced in the field of view. Here a pair of steps as a tripod will come in with excellent effect. Let the steps be planted rigidly parallel to the wall, the camera placed on the top, and the view focussed in the ordinary way; if a small step cannot be used, the focus must be so arranged as to allow for a little extra distance. Then all that is necessary is to push the steps, camera, and all, right against the wall, and everything will be in the right place on the ground glass.

Very probably it will be found, when all this is done, that the focussing screen cannot be removed to make way for the dark slide, or that the shutter of the latter has no space for being withdrawn. There need again be no difficulty. All that is necessary is to ascertain the relative position of the camera to its support, either by pencilling or scratching lines corresponding with its sides on to the top of the support, or, failing that, placing a couple of heavy books one on each side, so that the camera can just be withdrawn without moving them. This allows it to be removed and replaced without any shifting of the position of the image. The slide may now be inserted, the shutter withdrawn, and the whole replaced ready for exposing. There is not the slightest difficulty in succeeding if this be carefully done; and, indeed, occasions may arise

when this removal from the camera stand, charging with slide, and replacing, may occur when the actual focussing is done in the usual way. When the camera is on the stand, a simple plan of marking its position is to stick a few pieces of postage-stamp paper on its underside and just against the edges of the triangle.

We will conclude this aspect of the subject by referring to levelling the camera. In some otherwise excellent cameras there is not complete parallelism between the front and the ground glass, and as it is so easy in a building to run the eye along the front of the camera, and any door, window frame, or pillar, to ascertain that it is truly vertical, the spirit level itself is apt to be discarded and evil may then result. For it is ever to be remembered that to ensure parallelism of the vertical lines in a picture the uprightness of the front must be entirely ignored: it is the ground glass that must be perfectly upright; no matter how rigidly perpendicular to the floor the front may be, if the back deviate in the slightest sloping lines will result. Therefore, before leaving the focussing let the back be ascertained, either by level, by plumb-line, or by eye comparison with surroundings, to be truly and exactly vertical.

EXHIBITORS, photographic or otherwise, at the late French Exhibition have no occasion to complain of the number of medals awarded by the Jurors in the different sections. But it appears on this occasion awarding and giving are totally different things. It is true that the exhibitor to whom a gold or a silver medal has been awarded can have it by paying for it, and on no other terms. He will be presented with a certificate of the award, but the medal itself, if he has it, must be paid for. The system of charging for medals which have been awarded is not altogether unique at Continental exhibitions. However, it is the award that is most valued, and few English exhibitors who have gained gold medals will, we imagine, care to expend the necessarily heavy sum for their acquisition, whatever may be the case with regard to silver medals. We have been given to understand that medals, *facsimiles* of the real ones, but of base metal—plated or gilded, as the case may be—are, or will be, supplied commercially.

ALTHOUGH the late Paris Exhibition was such a grand success, both as regards the show itself and the number of its visitors, it appears to have been far from a success financially. It is rumoured that there is a considerable deficit. Perhaps this fact may have something to do with the medals not being presented. We have known, in England, of medals being awarded but not given by reason of the financial failure of the undertaking, but not in an exhibition of an international character.

RECENT legislation on the subject has given an immense impetus to electric lighting. Within a very short period there will scarcely be a district of London—or indeed any town of moderate size—where the electricity will not be procurable by photographers without having to go to a heavy expense for plant. This will be a very great advantage to many; for there is no question that the arc light in the studio, when daylight fails, is a great acquisition, as those who have it can carry on their business while others are remaining idle. It is not alone in portraiture that artificial light is useful, but in copying and enlarging. Indeed, most of the work in connexion with the production of type blocks is done by the aid of the electric light. Often a subject has to be photographed and the block produced ready for the press within a few hours; but for the electric light this business could not be carried on as it is now. The time, we imagine, is not far distant when the majority of well-to-do studios will be provided with the arc light as an auxiliary.

A FEW weeks back we alluded to the rapid spread of photography as proved by the number of new societies springing into existence and

the interest taken in their meetings. It is gratifying to note that some of the old ones also show increasing prosperity. The balance-sheet of the Photographic Club, recently issued, shows that it possesses a greater number of members and a larger cash balance than it has had at any time during the ten years of its existence. All this speaks well for photography.

Do some of our dry-plate manufacturers sufficiently consider the importance of packing the plates? That the plates are carefully protected, so far as light is concerned, cannot be denied; but is the material used in many cases really suitable for the purpose? It is not unknown in the experience of makers that a batch of plates, which were pronounced perfect when they were first issued, unaccountably become deteriorated after a few months' keeping. May this not, in many instances, be attributed to the paper or the boxes used in the packing?

It is a recognised fact that plates kept in dark slides are sometimes injured by exhalation from the material used for the hinges of the shutter, and sometimes from the colour used for blacking the slide. It is well known that paper in contact with the film, generally, has a marked influence upon it, as witness the effect of the strips of paper used to separate the plates if they have been long kept. Seeing the action the dark slides may have on plates kept in them, one may readily imagine that some papers may, with variations of the temperature, emit fumes which are equally as deleterious to the plates as those given off by the slides, and, with the present system of packing, there is an air space between each of the films for their circulation. It is a noteworthy circumstance in connexion with this subject, that it is the margins of the plates that first become deteriorated by long keeping, and it is these which would be first influenced by any baneful emanations from the packing paper.

Now that transparencies for the stereoscope and other purposes are becoming more general, many complaints are made that the ground glass supplied for backing them is far too coarse. There is no question that much of the ground glass sold for photographic purposes generally is of such a character that it materially detracts from the delicate beauty of the picture, particularly if it be a small one—a stereoscopic slide, for example; especially is this the case with the glass with embossed borders supplied with the metal frames. Much of this glass is not ground at all, but greyed by the sand-blast process. By this method, it is said, any degree of fineness is obtainable, yet we must confess that we have never seen any sand-blasted glass that was, to our taste, fine enough for stereoscopic transparencies. The finest and best glass for this purpose we have ever met with was that used for the transparencies of Ferrier and Soulier, some thirty years ago. This extremely fine surface was said to have been obtained by hydrofluoric acid.

It is easy enough to grind glass with an exceedingly delicate grain by using emery in a sufficiently fine state of division. The finest flour emery, as met with commercially, is much too coarse for the purpose if used as purchased. However, from it the finest particles—and these answer well—are easily separated from the coarser in the following way:—Take two or three pounds of flour emery and stir it up in a large vessel of water; the coarser particles will quickly settle to the bottom, leaving the finer ones in suspension. After a time the water is poured off into another vessel and the suspended emery allowed to subside. It is then collected and dried, or it may be used wet. The longer the coarse particles are allowed to subside the finer will be the decanted emery; three or four minutes will usually yield a sample which will give an exceedingly fine grain. The way to grind the glass is simply to apply a little of the emery with water and grind the surface, with a circular motion, with a small piece of plate glass used as a muller. Much labour will be saved by starting with patent plate glass, as its surface is quite even and only requires greying. Those who have a difficulty in obtaining fine glass for their focussing screens should grind their own.

MANY of the old French stereoscopic transparencies were backed with a varnished surface. One of the varnishes used, if we remember rightly, was composed chiefly of a solution of white wax in chloroform. Matt varnish is an admirable substitute for ground glass for transparencies, and the fineness or coarseness of the grain is perfectly under control, though, it may be mentioned, if it be made to give a very fine grain it is sometimes difficult to obtain a perfectly even surface on large plates.

THE NEGATIVE IMAGE.

IV.

THE treatment of prepared silver bromide plates, in order that visible positive pictures might be taken upon them, is an idea of comparatively old standing. "An ordinary gelatino-bromide plate," wrote the author of *Modern Dry Plates* in 1881, "darkens in a few seconds under the action of light, and if exposed beneath a negative for some hours a picture full of detail is obtained, which, however, disappears in the fixing bath. By fuming the plate with carbonate of ammonia the darkening proceeds much more rapidly."

Were this information revised up to date, it would doubtless be considered desirable to amend the statement that exposure under a negative for "some hours" was necessary, even with the very slowest of the commercial plates now retailed, except, perhaps, in a highly unfavourable light. Parenthetically, it may be noted that the slow plates, which are invariably coated with a compound haloid, have, relatively to their common sensitiveness, a higher amenability to the visible action of light than plates of pure bromide.

The "disappearance of the picture in the fixing bath" complained of, is a partial confirmation of the writer's experience of the remarkable solvent action of hyposulphite over images obtained upon debromised films, the difference being that in the latter instances the disappearance was incomplete, and was not observed until after many hours' immersion.

Of any experiments having for object the production of visible negatives by submitting the prepared film to the action of reagents no details have been met with. Closely allied to the subject, however, was the frequent recommendation, as a means of increasing sensitiveness immediately before exposure, to exhibit the plate to the fumes of strong ammonia. Such a proceeding was at best open to one serious objection, namely, the difficulty of ensuring uniform activity, and, of course, was impracticable for outdoor photography.

From time to time numerous other bodies have been suggested as capable of influencing the sensitiveness of the prepared film; of assisting or promoting the action of the usual developing solution upon the invisible impression, and so forth, with the particulars of which many are, doubtless, acquainted. Whether any real benefit is derivable from such devices is matter for legitimate debate. The field of experiment, however, still possesses an open aspect, when we observe how ardent and indefatigable are the modern endeavours to abbreviate the exposure by augmenting the efficacy of the older developing compounds and introducing new agents, that should command a more general admiration than they receive, if but a few of the properties that are attributed to them are not imaginary. It is to be remembered that the introducer of hydroquinone claimed that by its use exposure could be reduced one-half; experience has signally failed to confirm the claim. In reference to the history of this developer, it will possibly edify Captain Abney, Mr. W. T. F. M. Ingall, and other workers, to be blandly informed by the conductor of a one-year-old contemporary that "the introduction" (my italics) "of hydroquinone as a developer was largely facilitated by our advocacy" (also my italics). The substance in question was introduced as a developing agent as nearly as possible ten years ago; its properties were most exhaustively examined and discussed between the years 1884 and 1888, and neither our general nor our particular knowledge of those properties has received any addition of novelty or importance from the commercial exploitation of which hydroquinone is at present the victim.

In the previous article we were occupied in tracing the effects of light upon silver bromide, from which, granting the correctness of the chemical change wrought by sodium sulphite in dilute solution, as expressed in the equation, a portion of the halogen had been abstracted, leaving a compound the precise constitution of which must remain unknown, but which, from the marked dissimilarity of its behaviour to that of normal haloid, and the unvarying constancy of its reactions, must nevertheless be considered a true and distinct chemical substance. Furthermore, it was sought to be shown that the products of light and developing agents upon debromised films had an identity in common. Conceding the provisional accuracy of the deductions arrived at, and the experiments upon which they are founded as capable of repetition

and endorsement, we are encouraged to inquire of what practical use, if any, such properties may be made?

Is it, in fine, possible to produce in the laboratory a stable body analogous in composition to the material of the debromised film? Given an affirmative answer and the substance successfully isolated, is it practicable to form an emulsion with it? More: Would such an emulsion take so high a degree of sensitiveness as to give visible images with short exposures; in alternative terms, would light itself and alone reduce this hypothetical lower combination of silver and bromine with total separation of halogen? If so, and allowing fixation to interpose no difficulty, would the resulting negatives be of a kind to obviate intensification or other after-treatment?

Such questions are, of course, not to be answered without a prolonged invasion of the domain of research; but it is not unprofitable at this stage to revert to Mr. Carey Lea's papers upon a kindred subject, and to note that he was able to prepare in the laboratory photo-salts identical with the material of the latent image, and this, not by one method, but by very many; and that he produced by chemical means a sensitive body resembling in every respect the substance formed by acting upon normal haloid with a reagent. It can consequently be understood why it is to be reasoned that an effect corresponding to that produced by sodium sulphite and similar bodies in dilute solution upon a film of normal bromide, is to be duplicated in the pure haloid at or before emulsification. It is worthy of remark that, notwithstanding his observation of the great superiority in visible sensitiveness of photo-bromide to the normal salt, it did not occur to Mr. Lea, practically, to test that property.

One word as to the conflicting theories anent the latent image. If we bear in mind that light subjects silver combinations almost entirely and invariably to a reducing action, and it is discovered that an exact analogue of the product of the decomposition is to be prepared by chemical substances, it is logical to seek an answer to the problem within those lines. We have but to study the chemical action of the spectrum upon other metallic compounds to recognise the force of this principle of the interchangeability of light and chemical bodies. Almost always where light induces partial or complete reduction, we may find that a parallel is to be maintained by chemical agency. Hence the persuasion of the writer for leaning to the inclusion of the silver salts under the same law, and that whether we call the products of light upon them sub-salts or photo-salts, the production of analogous substances in the laboratory with the same facilities that attend the preparation of other bodies having a similarity to those formed by light of their higher compounds, is a clue to the problem not lightly to be rejected.

For light, whether it acts by oxidation or by reduction, has, over numerous compounds, an influence perfectly comparable to most chemical oxidising and reducing bodies. It is, in brief, a re-agent in the truest meaning of the term, with a range of power as wide as that illustrated by a chemical substance in its most concentrated and diluted states. If such a view became universal, our faith in remedies for under-exposure, our confidence in the plethora of developing formulæ of modern practice, would be frail indeed.

While deferring further pursuit of the attempt to establish the practicability of producing visible negative images in the camera, it would be affectation on the part of the writer to omit the admission that the tendency of much of the foregoing is wholly heterodox. The crude theory that silver, in combination with lower proportions of bromine than either chemical or photographic philosophy at present countenances, possesses properties of probable value may not be borne out in experiment; but the extent to which endeavour so far has gone is not opposed to the conviction that therein lurk the germs of an important departure.

THOMAS BEDDING.

ON THE DENSITY OF INTENSIFIED NEGATIVES.

[A Communication to the Photographic Society of Great Britain.]

NATURALLY, intensification of a negative has frequently to be touched upon by writers on photographic matters, but there seems to be only what I may term a qualitative knowledge of its nature. Indeed, the statements about density of deposit have always been more or less random. It was to see whether the density given by intensification had any exact relationship to the density given by mere development of a negative that my time has to a certain extent been employed. In a paper which I read at the Camera Club Conference, and which has appeared in its Proceedings, and in the pages of the photographic papers, I showed that the transparency of the different squares of a negative taken in a Spurge's sensitometer obeyed the law of error when the transparency of the square areas was represented by the ordinates to the curve, and the holes which admitted the light were taken as the abscissæ. I explained that the particles of silver reduced by the developer must be looked upon as being scattered at

random over the different areas, and that the transparency of the negatives was caused by the light penetrating through the interstices left by these particles. In a paper read subsequently at the British Association, and which was afterwards printed in an amplified form, it was shown that there was more than a probability that the number of particles deposited during development varied directly as the intensity of the light which previously had acted, and that the reason why the transparency of the different small areas did not also vary directly was due to the overlapping of particles owing to the random scattering. When the particles are once distributed, and intensification is carried out, it remained a question, hitherto unsolved, as to whether the diminished transparency obeyed any law. The sole answer possible to this question, it appeared to me, could only be arrived at by direct experiment. It must be borne in mind that the positions of all the particles of silver which have been reduced by development are fixed; and it was a question if the intensified negative might not obey the same law as the unintensified negative. It must not be forgotten that intensification by the ordinary mercury and silver method implies that each particle of silver is increased in size, and that therefore in all probability the same formula would apply to the intensified negative as it did for the unintensified one. The experiment was carried out in the following manner:—A plate was exposed in a Spurge's sensitometer for a time sufficient to give nearly opacity on the area to which the greatest intensity of light was admitted, i.e., with the light coming through the largest hole. The usual alkaline developer was employed. After development the plate was fixed, and the different opacities measured in the manner I have described on previous occasions. The curve was then plotted, taking for abscissæ the number of the holes of the sensitometer, and for the ordinates the transparency of each part. The theoretical curve was then calculated as is ordinarily done, and the observed and calculated values, when compared, show their agreement. The negative was next intensified by the mercury and silver process. It may perhaps be of value, and make this paper more complete, if the formula for the intensification be given, more especially as I wish to call attention to the fact that negatives I have treated with it remained unchanged, which unfortunately is not the case with the old mercury method. I have called this in one of my works "the best intensifier," and I certainly think it is so:—

1.	
Bichloride of mercury	100 grains.
Bromide of potassium	100 "
Water	10 ounces.
2.	
Silver nitrate	100 grains.
Water	10 ounces.

To this last is added a 100-grain (to the ounce of water) solution of potassium cyanide till the precipitate first formed is just not entirely dissolved. The plate is immersed in No. 1 till it bleaches thoroughly. It is then washed copiously and immersed in No. 2 till it is blackened right through the film, and again thoroughly washed. The sensitometer negative thus treated, after drying, was measured for a transparency. On applying the formula $T' = T e - \mu x^2$, x in terms of light, intensity being 25, where μ is the intensity of the light, where T is the total transparency, and T' that passing through a hole No. x , x being reckoned in this case, and in the proceeding from the hole in which no deposit was to be seen. It was found that the formula applied in this case as it did in that of the unintensified negative. The zero of the abscissæ was found to be the same in both cases, as might be expected from the nature of things.

In the ordinarily developed negative μ was found to be .00303, while for the same negative when intensified $\mu = .01015$. Total transparency T having measured 80° on the rotating sectors. The formulæ became in the two instances $T' = 80e - .00303x^2$ and $T' = 80e - .01015x^2$ when T and T' are the transparency of the deposits in the ordinary and in the intensified negatives respectively.

We thus find that $\frac{T'}{T} = e^{-.0112x^2}$, which shows that the density obtained by intensification is not directly proportional to that existing in the simply developed negative, as many have imagined, but increases more rapidly, in fact, as the logarithm. The gradation is much more rapid in the intensified negative than in its original state. It is not hard to calculate what the difference in gradation is, for we shall find it when the intensities of the light come in through any particular square of the sensitometer. This being so, we have $1e - .00303x^2 = 1e - .01015x^2$. Taking logarithms on both sides of the equation we get $\frac{x}{T} = 1.207$. That is, the range of gradation of the one is about 1.3 times that of the first one, the range being reckoned as derived from the sensitometer. If a little thought be given to

negative that requires intensification, it will be seen that the highest light falls short of anything like good opacity. Suppose that the greatest opacity was such that $\frac{1}{16}$ of the light passed through it, then by intensification the density would be so increased that only $\frac{1}{256}$ of the light would pass. For printing purposes the $\frac{1}{16}$ transparency is nearly equal to total opacity. But the fact must not be lost sight of that intensification is absolutely hurtful if the opacity in the high lights is what it should be without it. The details in the high lights, which may be very delicate shades of light, will be represented very nearly as opaque as the highest lights themselves, and they will appear as blanks when the negative comes to be printed.

I trust that the results I have given will be of some scientific value, for the more we know about quantitative photography the more useful we make the art generally. I dare say to a large majority of those attending the meeting this paper will be voted as too mathematical; but I think even a dull mathematical paper, if it contains anything novel, should be read before the Society, whose *raison d'être* is to foster not only the art side, but also the scientific side of photography. I can conceive of no greater proof of this than to look at these walls on which are so many splendid examples of art, and then on the black board, where we only see formulæ and apparently shapeless curves. The connexion between the two may seem remote, but I believe that it is by fostering the latter that the former will make any real progress. W. DE W. ABNEY, R.E., C.B., D.C.L., F.R.S.

SPIRIT PHOTOGRAPHY.

[THE writer of the following article, Mr. Henry J. Newton, is entitled to speak on the subject of Spirit Photography with a certain degree of authority because, as a photographer, he is and has for many years been the President of the Photographic Section of the American Institute, while he is further, and has long been, the President of the First Society of Spiritualists, New York.—Ed.]

WHETHER spirits have been or can be photographed is in the minds of many still a mooted question. When the subject was first brought to public notice, the law of optics applicable to such cases which science has promulgated and adapted required that a subject to be photographed must be to a certain extent opaque; in other words, a perfectly transparent body could not be photographed, it must be dense enough to reflect sufficient rays of light to project a visible image on the ground glass of the camera. At that time I believed these views to be correct, therefore, when questioned as to my belief in the truth of statements made, that through certain mediums spirits had been photographed, I pointed out the obstacles in the way and stated that to my mind, as I understand the laws governing such cases, they would be insurmountable.

At that time Spiritualism had developed but a limited variety of phenomena, and occupied a very different position in the world from what it does to-day, and the scientific theories which prevailed thirty years ago have in many instances been modified, and entirely changed in others. Whether or not we know anything more about light than we did then, we merely know more about some of its properties. The drift of scientific investigation, with reference to the constituent properties of light, point prophetically to the probability that in the no distant future science will adopt the theory that electricity and light are identical. Should this be so, it will not follow that we shall know practically anything more about light than we do now.

When photography was first introduced, and for many years after, science claimed that the action of light on the haloid salts of silver was a chemical action. This claim went undisputed and unchallenged until about the year 1865, when one of our most noted American chemists published the result of a series of experiments bearing upon this question. In his published statement he says that he became thoroughly convinced that the action of light on the sensitive film was purely mechanical and not chemical. The theory was that light travelling with the velocity which has been demonstrated, must, in coming in contact with any substance, exert a degree of physical force corresponding to its density and rapidity of motion, therefore, when the light impinged on the delicately prepared film, sufficient mechanical action resulted to produce the photographic image.

He states that one of the experiments which he made, and which to his mind was conclusive, was in submitting the prepared sensitive film to the delicate pressure of a medallion or uneven surface (I think he used a fifty cent piece) in his dark room, and then applied the developing solution, and an image was developed the same as if the plate had been exposed to light in the usual way.

This fact demonstrated the possibility of producing an image equivalent

in all essential respects to a photographed one in a dark room without the interposition of actinic light in any form. This was exceedingly interesting to me, and furnished stimulus to further experiments in occult photography.

The fact would seem to have been established that a photograph could be formed on the prepared plate by physical manipulation in the dark room, and I had many times witnessed the exercise of spiritual force infinitely greater than that required to affect a sensitive plate by an invisible, individual intelligence, and the question arose in my mind why images could not be formed by some invisible expert without the use of light, and with much less effort than is required to write between two closed slates. Additional evidence of the physical force of light was furnished by experiments conducted by Professor William Crookes, one of the most distinguished scientists of England, and Editor of the *Chemical News* of London.

He constructed an instrument which he called a radiometer, which was made by placing in a glass globe, or bulb, a wheel with four delicate fan-shaped arms, so arranged as to revolve something on the principle of a windmill. After exhausting the air from the glass bulb, it was hermetically sealed; the wheel was then in a vacuum, and it was found that this wheel would revolve when a ray of light was permitted to fall upon it, and, furthermore, the rapidity of the revolutions was in the ratio of the intensity of the ray of light. I have used this instrument to accurately measure the comparative quantity of light necessary to affect the sensitive surfaces prepared by different manufactures of photographic plates.

In the early part of my experiments, the idea of full form materializations had hardly been broached, and therefore did not form an essential element in my methods as it did afterwards. It is not my purpose in this article to detail any of my experience with the many mediums who have kindly volunteered their services, as that alone would make a long article; suffice it to say, that I obtained two or three pictures which were produced by spirit power, and about which fact there can be no reasonable question. My purpose mainly is to point out a way by which any medium who believes him or herself an instrument for producing spirit photographs can know beyond a peradventure that whatever results are obtained of an abnormal character on the sensitive plate through their mediumship can be relied upon as genuine.

First, however, I wish to say something more about light, so that the reader can more readily understand the whole subject. A photograph can be made in light from which the visual ray has been abstracted. It must be borne in mind that the visual ray in the solar spectrum is the ray which excites the optic nerve and produces the phenomena we call seeing; therefore, it follows that light from which this ray has been abstracted will be, as far as our vision is concerned, darkness.

In analysing the solar ray for the purpose of experimenting, the prism used should be made of transparent rock salt, as this does not absorb the heat ray, which glass will more or less. By passing a delicate thermometer along the spectrum it will become manifest that the heat rays reside between the visible rays, and increase in intensity as we approach the least refrangible end of the spectrum, and we find the greatest heat some distance beyond the red ray. This ray is not, however, the one which produces chemical action.

It will be found that the chemical ray is also invisible, but increases in power as we proceed towards the most refrangible end of the spectrum, and the greatest energy is manifested some way beyond the visible violet ray, these two invisible rays acting with increased energy as we approach opposite ends of the spectrum.

It is evident that neither of these rays excite the optic nerve or produce the phenomena we call vision, and neither of them are coincident with the visual ray, and therefore do not focus at the same point when transmitted through a single meniscus lens upon the ground glass of the camera.

You will now more readily understand the following experiments, for which purpose use any ordinary camera and achromatic lens. Set up the object you wish to photograph—a good steel-plate engraving answers an excellent purpose—and focus it on the ground glass. Have prepared a glass cell large enough to cover the front of the lens, and about three-eighths of an inch thick. Fill this cell with bisulphide of carbon, which is a perfectly white, transparent liquid. Into this liquid put a small quantity of iodine sufficient to change it to a deep violet colour. This liquid so prepared has the power to absorb all the visual rays from the solar spectrum which pass through it. Place the cell so prepared directly in front of the lens, and in contact with it, in such a position as effectually to exclude all white light from the camera; there can be, therefore, no white light or visual ray enter the camera through the lens, and by placing the focussing cloth over your head and examining the interior of the camera, it will be found to be perfectly dark, yet the actinic ray is not excluded; and, if

under these conditions you expose the sensitive plate on which you have focussed, you will be surprised to find that the photographic image has been produced on the sensitive plate nearly as quick as if the cell of violet-coloured liquid had not been there. As wonderful as these results are, they are but a small part of the wonders revealed in experimenting with light, but only a few of them are pertinent to this subject.

The absorption of light by certain substances, and its retention for a limited period, may properly be noticed briefly here, from the fact that it has been alleged that some mediums for spirit manifestations have made use of this fact to deceive their patrons. Whether this be true or false, I have formed no definite opinion, for the reason that, so far as I know, there has been no reliable evidence produced to prove such statements to the satisfaction of a conservative and careful searcher after facts. In the hands of a crafty and designing person, having knowledge of this peculiar property of light, I admit it would be possible to impose upon the ignorant and inexperienced, but any one at all familiar with experimental exhibitions of light held by absorption would not be likely to confound it with any of the most ordinary spirit lights. The major part of what I have read in spiritualistic papers touching upon this subject have been exhibitions of ignorance regarding the whole matter.

Any medium for spirit photography should have for a photographic outfit a stereoscopic camera. With such an apparatus there is necessarily made simultaneously two pictures of the same object, as the camera is arranged with two perfectly matched lenses. If on a sensitive plate exposed in a camera so arranged there should appear an image on one part of the plate from one of the lenses, there must of necessity appear an exact duplicate on the other part of the plate from the other lens. Now, as all so-called spirit pictures which are fraudulently obtained are made by manipulating the plate either before or after exposing, when there is no visible image to guide the operator, it is with him either the work of measurement or of guessing where the figure which he improvises shall be placed; therefore, it will readily be seen how impossible it would be to produce two fraudulent pictures exactly alike, such as the stereoscopic instrument would produce.

If, however, it were possible by an ingenious person using careful measurements to produce two pictures apparently simultaneously so near alike as to deceive an inexperienced person, its genuineness can readily be determined by having prints made from this negative and mounted in the usual stereoscopic manner, which is to cut the print in two pieces through the centre, and place the right-hand picture on the left of the card mount, and the left picture on the right end, then look at it through a stereoscope, and if it is a genuine stereoscopic picture the figures will stand out in relief, if fraudulent they will be flat. Any medium for spirit photography who will adopt this method will avoid all danger of ever being called a fraud if they obtain a genuine stereoscopic picture of a spirit.

I have in my possession a stereoscopic spirit picture made in Central America by a friend of mine, and I have also seen the negative. The story of its production and the recognition of the spirit picture by relatives in London give additional interest and value to the picture.

—The Better Way.

HENRY J. NEWTON.

EIKONOGEN.

HERZ EUGEN VON GOTHARD, Principal Astronomer of the Herenz Observatory, whose recent stellar photographs obtained with orthochromatic plates and a reflector have become famous as a new departure, supplies the following notes from his experience of eikonogen.

"I employ," he says, "two solutions of the following composition:—

SOLUTION 1.

Sodium sulphite	200 grammes.
Water	3 litres.
Eikonogen	50 grammes.

SOLUTION 2.

Soda	150 grammes.
Water	1 litre.

"For use, three parts of Solution 1 are mixed with one part of Solution 2.

"Solution 1 keeps in good condition for at least three months. Dissolved in pure distilled water eikonogen decomposes very rapidly, and in an open glass turns yellow in a few minutes, then brown, and finally the colour of coffee. The undissolved powder also becomes brown if not kept in an air-tight vessel. Eikonogen acts very energetically, bringing out the image quickly, and finishing rapidly. When the development is carried too far, yellow or green fogging frequently takes place, even when the solution is diluted with water. One disadvantage of eikonogen is that it easily produces too hard negatives on account of its energetic

action. If the solution is diluted with half its volume of water the negatives are much softer and more harmonious, but the action is considerably slower and green fog easily appears. The same solution can be employed three times in succession, even for instantaneous exposures, but after that it loses power. The plates must be very carefully washed after developing if one intends employing an alum bath, otherwise considerable precipitation takes place in the film destroying the negative. The alum bath may, however, be omitted, and an acid sodium solution alone employed. Bromide of potash acts as a powerful restrainer. As regards price, the cost of eikonogen is about the same as that of the soda, pyro, or hydroquinone developers, but as it can be employed several times in succession, it comes considerably cheaper."

A NEW PLATINUM TONING PROCESS.

[A Communication to the Camera Club.]

THE very great stability of the metal platinum, superior even to that of gold, has from the very commencement of photography naturally excited many workers to experiments, with the view of making it a basis for a positive printing process that was to defy the ravages of time. As far back as 1832 we find recorded experiments of Sir John Herschel on the action of light on salts of this metal; he was soon followed by Robert Hunt, amongst others, who has left a very detailed account of his numerous experiments in the pages of his well-known works on *Light* and *Photography*. In more recent times Willis entered the field, and his experiments resulted in the well-known hot and cold-bath platinum processes, which will hand his name down to posterity as the father of all platinum printing. Of the numerous array of smaller workers I will not weary you; their efforts are to be found here and there in the earlier numbers of our own and foreign photographic journals.

But I cannot continue without devoting a few words to the experiments of Mr. Burnett, of Edinburgh. This gentleman appears to have tried every salt of platinum as toning agents, and, moreover, appears to have specially advised the use of the platinum in preference to the platonic salts, and also advises their use as developers of images formed on uranic and ferric papers, thus closely foreshadowing the present platinum processes.

A careful study of all these experimenters' works shows, however, that the platinum salts are not practically reducible by the action of light, even when in the presence of organic substances, but if it be wished to obtain an image in platinum black, it is first necessary to form a provisional image, visible or not, and then, by means of a toning or substitution process, convert this provisional image into one formed of platinum.

Every kind of platinum printing at present known is subject to this law, which distinctly separates it from the ordinary types of positive printing in silver, whether direct or by development. In these processes the image is formed of silver which has been blackened by exposure to light, or rendered prone to reduction by suitable agents, and this blackening forms the image. In platinotype the image is formed of another metal, to be replaced later on by platinum, and by a substitution process analogous to that in which the silver image is sometimes partly replaced by the gold of the toning bath. Gold toning is sometimes described as a *gilding* process, and it is assumed that the silver image is coated, or *gilt*, with a thin layer of gold, but I think that there can be no doubt but that it is a pure chemical substitution process, three atoms of the silver image being replaced by two of gold, the silver chloride, or oxy-chloride, that is so formed being subsequently dissolved out in the hypo.

The well-known modern platinotype processes of Willis and Pizzighelli come under the above rule as toning processes, the only difference being that the metal of the provisional image is iron instead of silver, and at present all known platinotype processes may be classed together under the head, *toning processes*.

The first gentleman who appears to have practically used platinum as a toning agent was a Frenchman named M. Carranza, who described his process in *La Lumière*, February, 1856, and *Photographic News*, vol. i., p. 251. He used a dilute solution of platinum chloride acidulated. Now the commercial chloride of platinum is, according to Pizzighelli, chloro-platinic acid; the real platonic chloride is PtCl_4 , but is insoluble in water, and therefore hydrochloric acid is added, making the formula $\text{PtCl}_4 \cdot 2\text{HCl}$; it further contains $6\text{H}_2\text{O}$. Now in this salt, which is the common platonic chloride of commerce, sometimes called bichloride, a relict of the older chemistry, the platinum is tetravalent, that is to say, its molecule is formed of an atom of platinum united to four atoms of chlorine, and

therefore, when a substitution is effected, four molecules of a univalent salt (that is a salt which is satisfied by a single atom) must be brought

up to the platinum salt, and each take one atom of chlorine before the platinum can be reduced to the metallic state. Silver is such a metal, and if the atomic weights of this salt and platinum were the same, it would mean that four parts of metallic silver must be converted into the chloride before one part of platinum metal could be formed, and therefore the deposit would only be one-fourth as thick. Or again, if their colouring properties were equal, after the substitution the intensity of the platinum image would only be one-fourth that of the provisional silver image. However, platinum has, weight for weight, like gold, a greater colouring property than silver; and, furthermore, the substitution process is never very thoroughly carried out, but still there is a very decided loss of intensity in a print which has been thoroughly toned by platonic chloride. It is extremely probable that the free hydrochloric acid has also a deleterious effect on the image; for in the best toning formulae, which contain platonic chloride, it is recommended to first neutralise the hydrochloric acid and then re-acidify the solution, preferably with nitric acid. But even after this precaution it cannot be said that there is any satisfactory process of toning by platonic chloride at present described.

In comparing toning processes by means of platinum with those where gold is used, it must also be remembered that the platinum is much less easily reducible than gold, and Mr. Willis found, in his early experiments, that the salt was by no means to be precipitated like the chlorides of gold or silver. However, the fact that oxalic acid greatly aided the reduction of gold from its salts had long been a known fact in chemistry, and its similar action on the platonic salts had also been noticed by Döbereiner (Schwergger's *Year-book*, vol. xvii., p. 122), who found that chloride of platinum in solution of sodium tartrate, or oxalic acid, separated out under the action of light in the form of a thin film. This fact appears to have also been known to Willis, who in his early experiments found that a hot solution of oxalate of potash instantly precipitated the platinum from the chloride when in the presence of a protosalt of the heavy metals, in his case ferrous oxalate being the one used.

But, as we have already seen, the platonic chloride demands that four molecules of ferrous oxalate shall be converted in order to liberate one molecule of platinum, and since the ferrous oxalate has to be formed by the agency of light, it follows that the proof must be very much overprinted in order to get enough of the ferrous salt to make the image of sufficient intensity.

It was at this point that Willis introduced his great improvement which made platinotype a practical process. He found that platinum was capable of forming a second series of chlorides, in which the metal acted as if it were divalent. Such a chloride is known as platinumous chloride, PtCl_2 , in which we may suppose that where two of the bonds of the platinum atom are satisfied, each with a chlorine atom, the other two mutually satisfy each other.

It is evident, at first sight, that with this salt it will only require that two molecules of any univalent metal be presented to the platinum salt, when they will take up all of the only two chlorine atoms in it and liberate the metal, and therefore with this salt we only require half as much reduction to produce an equal effect as it would were the platonic chloride used. We may further assume that the two bonds that are satisfied by each other are in an unstable equilibrium, and can easily be dissociated, and thus accelerate the rupture of the complete molecule and render the ultimate precipitation of the metal more speedy. I think that there can be no doubt that experiment and practice has proved the correctness of the above theories, and I hold that platinum toning only became a practical possibility from the day that Willis employed the platinumous instead of the platonic salt.

Platinumous chloride itself is an insoluble salt, but it forms with the halogens double chlorides which are freely soluble in water, the salt that has proved the most suitable being the double chloride of potassium and platinum, known as the chloro-platinite of potassium, 2KClPtCl_2 , or K_2PtCl_4 .

In the most recent of the platinotype processes, known commonly as the cold-bath process, or Willistype, this salt is practically used, the provisional image being formed of ferrous oxalate, in which, however, the organic matter in the sizing of the paper certainly has some action; this provisional image is converted into platinum by the addition of the chloroplatinite of potassium, oxalate and potassium, and monopotassic orthophosphate, the quantities being as follows:—

D.

Oxalate of potash	5 ounces.
Monopotassic orthophosphate	3 "
Water	50 "

P.

Platinum, chloroplatinite	60 grains.
Water	2 ounces.

Normal developer, D 3 parts + P 1 part + water 2 parts.

This developer is brushed over the print, or the print is floated on the developer; the faint lilac image very rapidly changes to a deep rich black, the print being completed in from one-half to one minute. The unaltered iron salt has then simply to be dissolved by suitable acids, and the proof is complete.

When we come to the other sort of platinum toning, where silver is used as the basis, we see that very much the same chemical changes obtain. The colouring matter of which the image is formed is more complex in its nature, being probably a mixture of metallic silver, purple subchloride, and a deoxidised organate of silver, which Messrs. Davanne and Girard very appropriately term a *lake*.

It is, therefore, difficult to say precisely whether any particular one, or all, of these compounds have an action. I am inclined to believe that the violet subchloride practically plays no part in the transformation; for if the print be treated with common salt, all the violet subchloride is destroyed, and the reddish organate of silver alone remains, but yet the toning goes on as well (perhaps a little more slowly) as usual. But, at the same time, if a print be fixed in hypo before toning, as far as my present experience goes, I find that the print refuses to tone; with plain paper prints, however, there is a slight tendency to tone.

There is a certain contradiction in this which I cannot as yet solve or explain.

But whatever may be the precise composition of the salt that forms the provisional image, the action is precisely the same as in the case of iron. Assuming it to be metallic silver, we should get the following equation, parodying that of Berkeley:—

—this is, of course, far from being correct, for we know that the silver is not wholly in the metallic state. However, the equation shows clearly enough that four molecules of the silver are converted into chloride before one of platinum is reduced, and these four molecules of silver had to be produced by the action of light.

With plain paper prints, that is, paper simply salted and excited, it is an easy matter to obtain some sort of toning with any platinum salt, but not so with albumenised prints; this fact was noticed from the very first by Haackmann (*Photographic News*, vol. i., p. 251). It would appear, therefore, that the reduced albumenate of silver that is formed by light has a mechanical action that tends to prevent a ready interchange between the two metals, and that we should therefore endeavour to soften the albumen by some agent, such as tartaric, acetic, or tribasiphosphoric acid added to the toning bath. I have, however, such a dislike to the surface gloss of all albumenised prints, that I do not take enough interest in them to experiment in this direction.

I have, however, for some time past, been trying to bring about a thorough toning of matt-surface silver prints by means of platinum. The goal I have aimed at is to have a print that can be examined in the printing frame as it progresses; the advantage of this for combination or cloud-printing is obvious. Secondly, the greater part, preferably the whole of the silver, should be replaced by platinum black—that is, that the print should not change colour when treated with mercuric, cupric, or other chlorides or oxidising agents. Minor points are that the print should not lose in intensity in the toning, that the colour should be variable, that some power of altering the gradation or scale of tones should be possible by slightly varying the toning ingredients; in short, that the process should be as perfect and as well under control as the cold-bath platinotype process, with the advantage that the paper requires no special precaution in keeping, and the image is plainly visible. So much for Utopia; now for practice.

My first experiments were naturally made with the ordinary commercial platonic chloride, and I found that it certainly was capable of toning, although slowly, and as the formula shows there should be, I got a great reduction of half tone, and general loss of intensity over the whole print. Following the lines of Willis, I tried the addition of oxalate of potassium; this certainly improved the toning of the platinum, and it was possible to completely convert the image into an agreeable tone, but the loss of intensity was very great, and the prints, to have any vigour at all, had to be printed very deeply. The effect of this was to cause granulation in the darkest shadows, that is, where the print was solarised and had the well-known metallic lustre due to this cause. In this the silver prints show a striking analogy to the iron ones; it is a well-known fact, both in the hot and cold-bath platinotype processes, that after a certain exposure the image solarises, and becomes lighter in colour than the surrounding

parts. I have repeatedly noticed that these solarised parts, on development, also gave granularity. I cannot chemically account for this; I can only presume that in these solarised parts the metal has been completely reduced from the organate, and that it has a tendency to form into nuclei around which the deposit of platinum is more violent.

Finding, then, that the ordinary platonic chloride was unsuitable for toning, it was only natural at this stage to further follow Willis's example and use the platinous salt. This I did, and my first experiments were made with the ordinary developer as recommended by Willis in his cold-bath platinotype process. My very first trial gave me a very remarkable success, so much so that this developer is a very good toning formula in itself without any alteration. In my first experiments I proceeded exactly according to Willis's instructions. I, of course, washed the plain paper print to free it from the free nitrate, and then simply floated it over a little of the developing solution spread out over a piece of glass; the toning took place with the greatest of rapidity—in fact, quite as quickly as the ferric oxalate paper, the red-brick colour of the silver organate rapidly giving way to the black of the platinum. When this colour, viewed by transmitted light, had entirely disappeared, the print was fixed and washed in the ordinary way, and an image was left resembling very closely an ordinary platinotype hot-bath print in colour. I described this process, and showed some specimens at the meeting of the Camera Club, November 29, 1881, when Mr. Willis gave his demonstration of his then new cold-bath process.

During the winter I allowed my experiments to lapse, but in the spring, incited thereto by the appearance of Mr. Valentine Blanchard's toning process, which possessed considerable analogies, I continued my experiments.

With the ordinary platinotype paper the chloroplatinite of potassium is not reduced when applied to the paper in an aqueous solution, but requires the addition of a soluble phosphate or oxalate; but with the silver provisional image such is not the case, the platinum being rapidly reduced from the chloropotassic salt without any further addition. It is difficult to say precisely whether any advantage accrues from the addition of the oxalate; when present in large quantities it is injurious, giving a brown or yellowish colour to the delicate half tones, and when present in small quantities it appears to have no very appreciable effect, so that in my subsequent experiments I have entirely discarded all other chemicals but the chloroplatinite of potassium. At the same time, I am inclined to think that the oxalate may cause a more complete reduction of metallic platinum and so tend to permanency. Further experiments are wanted in this direction.

The next series of experiments were made to determine the solubility of, or the best amount of water to use with, the chloroplatinite of potassium. It must be confessed that but very little difference is to be found in the resulting prints from any variation in the strength of the developing solution. By difference is meant, of course, a variation in the scale of gradations, or intensity curve of the print. The sole difference between using a concentrated solution 1 in 15 (platinotype formula) and 2 grains to the ounce (1 in 218), is that the former completes its work much more rapidly—in fact, the change is almost instantaneous, and the print may be held in the hand and watched during the operation. In such a case it is, of course, preferable to either brush the solution over the print or else float the print on it. When more dilute solutions are used, the toning proceeds more slowly, and the print should be immersed in a bath as in ordinary gold toning. The results, however, will be sensibly the same, with the advantage in favour of the stronger solution, which has a tendency to give slightly more brilliant results. The strength that I practically use now is about 1 in 218, that is, a drachm of the platinotype solution is made up to two ounces, with which the toning proceeds quite rapidly enough to enable the developer to be brushed on. I will refer later on to the practical details of the process.

The alkalinity or acidity of the bath demanded also a series of experiments. I do not find any appreciable difference with results when the solution is acidified. The prints have perhaps a slightly blacker appearance, but that is all; but when rendered alkaline, the solution refuses to tone at all, even when a concentrated solution (1 in 15) is employed. This fact was very noticeable—so powerful was the toning solution, that when the wet print was immersed in an acid solution to neutralise the alkali, there was enough platinum left in the pores of the paper to instantly tone the print. Even when only a little alkali is present, I find the toning action is much slowed. In this respect my results differ from those of Gwenthan (*Photographic News*, vol. ii., p. 263), who says alkaline solution gives brown and acid ones blue tones.

With regard to the formation of the provisional image, all my early experiments were made on ordinary commercial matt-surface sensitised paper. I have used several brands, some obtained from the Civil Service

Stores, some from Marion's, Watson's, and Valentine Blanchard. The last two papers gave decidedly superior results, owing, probably, to their being more richly silvered. It is necessary in this process, if an ordinary negative is to be used, that the paper be somewhat rich in silver, as a good deal of this metal must be reduced in order to obtain a very dense deposit of platinum; in fact, with the same negative, it is not possible to obtain as deep a black on any brand of ready-prepared paper as can be obtained with the ferric oxalate paper of the Platinotype Company. A sufficient intensity for all ordinary purposes can be obtained, however, from any fairly plucky negative. The prints I show, together with the negatives, will give you an idea of the results that can be obtained from the ordinary material to be obtained from the chemist.

But I think it is one of the great advantages of this process that it is an extremely easy matter to sensitise one's own paper. It will at once be evident the artistic power this gives one; not alone are we confined to rough or hot-pressed parchment or plate paper, but we can produce our pictures on silk or cotton, leather or satin jean, or whatever material the texture of which we think may enhance the effect we have in view. The few examples I hand round, hurriedly and imperfectly executed, will, I hope, give you an idea of the power it puts in your hands.

Although foreign to my paper, I will here give you the salting and sensitising mixtures that I have found most suitable for the formation of the provisional image:—

SALTING SOLUTION.

Gelatine	90 grains.
Chloride of ammonium	60 "
Carbonate of soda (re-crystallised)	120 "
Citric acid (in crystals)	30 "
Water (rain or distilled)	10 fluid ounces.

Any gelatine will do. The ordinary gelatine of the housekeeper, sold by Nelson in one ounce packets, answers very well. The above quantity will be sufficient to make the above solution set into a weak jelly when cold. More or less can be added, according to the taste of the operator, or the amount of size the paper already contains. In the place of gelatine, starch or arrowroot may be used (for English animal-sized papers I prefer arrowroot), the resulting tone of the print varying slightly thereby. The quantity of the sizing must, of course, vary with the quality of the paper used. The object of the sizing is to keep the image on the surface; therefore, with a porous paper much, whilst with a glazed paper little, should be used. The above amount will be found sufficient for most papers, without causing any objectionable gloss after finishing.

I prefer the ammonium to the other chlorides myself, but sodium or barium can equally well be used, the proportions then being, for the above formula, sodium chloride, 72, or barium chloride, 138 grains. The paper should be floated on this mixture, or it should be brushed over it, care being taken not to wet the back. It should then be hung up and allowed to dry. In this state it may be freely exposed to light.

With regard to the sensitising solution, I much prefer the variation in the ammonio-nitrate of silver as introduced by Hardwich, the strength I use being sixty grains to the ounce. The following is the method of preparation:—Dissolve the sixty grains of silver nitrate in half an ounce of water; then add strong ammonia till the brown precipitate first formed is redissolved; then divide this mixture into two parts, and add nitric acid till it gives a distinctly acid reaction; then mix the two parts together, and make up to one ounce. This solution is ready for use at once, and only keeps in the dark.

This solution of silver oxide, dissolved in nitrate of ammonia, is undoubtedly the most rapid process; but, like other processes, when speed is desired, its manipulation is more difficult, and it does not keep. In this respect it is vastly superior, however, to the ordinary ammonio-nitrate process, which hardly keeps a few hours. Paper prepared with the above formula will, I find, keep a day, or even two, with care. A disadvantage is that it is impossible to float the paper on this mixture, but it has to be brushed over the surface of the paper, or applied with a glass rod in the usual manner.

Therefore I largely use the ordinary nitrate of silver process, using a bath of the same strength—sixty grains to the ounce. This bath can be used over and over again, and sheet after sheet floated till it is all but exhausted. With this bath, however, I prefer to slightly increase the amount of salt, making it, say, ninety grains. I find a paper so prepared to be fairly rapid, giving untuned prints of a rich colour. I find also that it is advisable to add citric acid to the above solution till all effervescence ceases, and the reaction is slightly acid. This is unnecessary if the paper be fumed, a process which, in very dry or very dull weather, I can most confidently recommend. For further details as to plain paper

silver printing I would refer you to the pages of Hardwich's *Photographic Chemistry*, and THE BRITISH JOURNAL OF PHOTOGRAPHY, leading article, 1878, page 78 and *ante*, where full practical details are given.

(To be concluded.)

LYONEL CLARK.

Foreign Notes and News.

THE Germans appear to have been excessively pleased with the Berlin Photographic Exhibition. We, last week, chronicled the fact that the greater number of the objects there exhibited had been removed to Königsberg, where they form a continuation of the great exhibition. Dr. Vogel has now made arrangements for their further removal, at the beginning of next year, to Breslau, where, for some three weeks, their presence will gladden the "friends of photography" of that town. Both Leipzig and Heidelberg had subsequently written to request that they might be made participants in the honour, but their petitions arrived too late. It would be difficult to find a better proof of the wide interest all classes in Germany take at present in things connected with photography.

HITHERTO, pliable films have had but a very limited employment in that country. Now, however, thanks mainly to the exertions of Dr. Arnold, they are gradually coming into use. In Berlin, Messrs. Heselkiel & Justi have established an agency for Anthony's sensitive films, and Herr Richter for Balagny's. Herr O. Perutz, of Munich, has also extended his business by adding a branch for film manufacture.

THE recently opened Polytechnic Institute of Zürich, besides being provided with chemical and pharmaceutical laboratories and workshops, also rejoices in the possession of a photographic department. This consists of a large room ten metres by 6.45 metres, communicating with which is the studio, three metres by six and a half. The dark chambers are situated in the basement, which is entered by a spiral stair. The large room contains the work tables and retouching tables, and is provided with a small, miserable, dark chamber. The basement is divided into four parts. One of these contains thirty-two small cupboards for the pupils to store their reagents in: the other three form laboratories, furnished with water-pipes, tables, &c. Here is placed an apparatus for drying plates, and an apparatus for enlargements. As only nine students can work at once, it has been found necessary, in consequence of the large number desirous of doing so, to organize work in "gangs." The glass roof of the studio has been provided with a number of water-pipes, which will enable snow or dust to be got rid of, and in summer help to keep it cool—a practical arrangement, which might perhaps be followed with advantage elsewhere. Switzerland, it thus will be seen, is following the lead of Austria and Germany in providing first-class instruction in photography. Will England ever feel disposed to follow suit?

THE 28th of last month was a date to be marked with a red letter in the annals of the "German Society of Friends of Photography." On that occasion they held their first meeting in the rooms of the Royal Kriegs-academie, which have been placed at their disposal by Field-Marshal von Moltke.

PROFESSOR DR. RIETSCHEL on that occasion spoke at some length on the subject of some very interesting experiments he had carried out with a mixture of hydroquinone and eikonogen solutions. It appears from the results he obtained that this developer acts more slowly than pure eikonogen, thus enabling the progress of the development to be more easily controlled. The mixed solution, he points out, keeps remarkably well—a quality which pure eikonogen does not always display.

DR. J. SCHNATTS has been carefully comparing hydroquinone and eikonogen. He has come to the following conclusions:—"When the solutions are of similar strength, and contain similar amounts of alkalis, the rapidity of development is about the same with both. With hydroquinone the blacks come out stronger, while eikonogen gives better half tones. All plates developed with eikonogen, however, require subsequent intensification, which one avoids by using hydroquinone."

THE *Mouiteur de la Photographie* gives a receipt for magnesium light which gives, when burning, a light of 20,000 candle power. The mixture recommended is as follows:—

Magnesium powder	20 parts.
Barium nitrate	30 "
Flower of sulphur	4 "
Beef suet	7 "

The suet is melted and kneaded up with the mixture, which is filled into zinc cases, 10 × 7 cm. Each such case holds about a pound, and will burn

for twenty seconds, giving a light that may be seen at a distance of sixty miles. This appears to be perfectly possible, for Dr. Miethe, who, some time ago, experimented with signal rockets containing a mixture of magnesium powder and chlorate of potash, found that the light emitted was visible from Potsdam to Oderberg.

RECENT researches by Signor Vittorio Aducco (published in the *Atti della R. Accademia dei Lincei*) seems completely to confirm the earlier results arrived at by Molescholt, that change of tissue in the animal organism is promoted by the action of light. Change of tissue, on the other hand, in the case of animals confined in the dark, takes place so slowly, and to such a small extent, that the nutriment ordinarily in reserve in the body is quite sufficient to keep life from becoming extinct for a very long time. We shall not be surprised to find the vegetarians making capital out of this piece of information, and recommending those desirous of living cheaply to supplement a vegetarian diet by existence in a darkened room!

MONS. JOLY, in a communication to the Société Française de la Photographie at their last meeting, points out that solutions of hydroquinone, when sufficiently concentrated, are no longer colourless, but possess a yellow tinge, varying in intensity with the degree of concentration. The spectroscope enabled him to prove that complete absorption of the blue and violet could easily be brought about, and by increasing the degree of concentration of the solution, one could succeed apparently in cutting off even the green rays. If this be so, the hydroquinone will, ere long, be figuring not only as a developer, but as the best light filter hitherto discovered, for any light it lets through, when sufficiently concentrated, will probably be quite unactinic.

APPROPOS of hydroquinone, it is certainly calculated to bring a smile upon the face of the most care-encumbered of our readers to learn that two Italian doctors have recently been recommending this reagent as a febrifuge. Surely the *mot* of the learned judge in a recent criminal trial, that a doctor was one who puts a drug of which he knows little into a body of which he knows less, could hardly have received a happier illustration!

Our Editorial Table.

THE THORNTON-PICKARD TIME SHUTTER.

THE aims of the firm by whom this shutter has been brought into existence have been high, and these aims have been carried into practical effect in such a way as to enable them to make high claims for it. In configuration it forms a nearly square mahogany frame, as shown in the cut, about an inch thick, and having a padded hole in

the centre, in which the hood of the lens is inserted. At the bottom is a small tassel, which, when pulled, draws up a spring roller shutter, which has in it an opening the full size of the lens. Pressure on the pneumatic ball causes its release. Worked as an "instantaneous" shutter, various degrees of rapidity can be obtained by the bracing-up of a spring; for protracted exposures it can remain open an hour or a day, while for brief time exposures, such as from a quarter of a second up to as many seconds as one may wish, its action is really

admirable, the mechanism for effecting this being both ingenious and simple. It is well made, and the various actions are effected without any jar.

MAGNESIUMLICHTES IN DER PHOTOGRAPHIE.

Von Dr. MAX MÜLLER. (Weimar: K. SCHWIER.)

THIS work, as its name indicates, is devoted to the application of the magnesium light to photography. It is illustrated by a well-executed portrait and the interior of a cave, the former by photogravure and the latter on albumenised paper, both being taken by magnesium. The author opens by giving an historical account of magnesium, and gradually leads on to the construction and uses of various flash lamps, several of them being known to English readers, although some are conspicuous by their absence. Several pages are devoted to the relative merits of lenses for employment in portraiture with magnesium light.

The book is a useful contribution to photographic literature, and we can only regret that it is printed in the German language, else would it secure many readers in this country. It contains fifteen cuts, has sixty-two pages, and sells at three marks.

MARINE PHOTOGRAPHS.

FROM Mr. James E. Goold, Newcastle-on-Tyne, we have received two large and fine photographs of H.M.S. *Victoria*, being respectively bow and stern views. They are taken while the ship is under full way, and while the guns in the turret are being fired. Mr. Goold's efforts to capture this man-of-war have been entirely successful.

PATENTS COMPLETED.

IMPROVEMENTS IN OR RELATING TO PRINTING PHOTOGRAPHS, ESPECIALLY "BLUE PRINTING," AND IN APPARATUS THEREFOR.

No. 16,715. ARTHUR RICHARD BROWN, The Park, Harrow, Middlesex.—*November 2, 1889.*

THIS invention relates to improvements in the method of and apparatus employed in photographic printing. The objects of my invention being to make a portable apparatus for photographic printing, and one more simple, cheaper, and much lighter than the frames at present used; at the same time, to take out creases from a crumpled tracing, and also to enable two different tracings to be printed at the same time with one apparatus.

I effect this result by means of an air or fluid pressure cushion or bag, preferably made of indiarubber or some such material, in combination with clips for stretching the tracing, thus doing away with the heavy plate glass usually employed. The sensitive paper is kept tight against the tracing by means of the air bag.

The clips for taking two prints at once may form a rectangular frame, open front and back. If one tracing alone is being printed it is then desirable to have pieces of webbing or canvas, &c., to form a back to the frame.

The frame when used is made in such a manner that it can quickly be taken apart and rolled up with the bag.

The air bag can if necessary be used with only a drawing-board or card-board to form a back for the bag, and the tracing pinned or fixed by means of clips to the board.

Also the bag can be used by itself for taking prints of letters from a letter book, or any book printed on one side, with a clip or its equivalent to hold the edge of the page down whilst printing.

The construction of the clips or frames, as will readily be understood, may be considerably varied, but I will describe some of the more likely forms.

Where a drawing-board is used simple spring clips may be employed in place of drawing-pins for fastening the paper to the board. Where the drawing-board is dispensed with and a frame of some kind has to be used, I prefer to employ light wooden longitudinal rods, say, for example, three, with cross bands of webbing where required, though in many instances the webbing can be entirely dispensed with. The papers are fastened by the ends, and for this purpose I employ any convenient form of preferably steel spring clips, which may extend across the whole length of each end, or may be divided, or several entirely separate clips may be employed; however, I prefer for this construction to employ a single long clip at each end, and so arrange it that the papers having been turned over a metal or other rod can be slipped in under the clips, which are sufficiently strong to prevent back-sliding; by this arrangement the papers are sufficiently firmly stretched, and the inflation of the bag will take out any unevenness, and also place the two papers in intimate contact.

If desired, a complete open frame may be made jointed at the corners, preferably by hinges with removable pins; a suitable groove or recess passes round this frame, and spring clips are so placed that when the papers turn round the rods are inserted in the groove, both rods and papers are securely held. Instead of using clips the framework may be divided at the groove, and when the rods and papers are inserted therein the divided portion of the frame may be brought together in any convenient manner as by screws and thumb-nuts.

Instead of the bands of webbing above mentioned a sheet of canvas or equivalent, paper or the like, may be used, and instead of the drawing-board a sheet of card or millboard can be employed.

Where it is desired to take two prints at once it will be understood that the bag is inserted in any suitable frame or clips, and lies between the two sets of papers, so that both are stretched as required.

The claims are:—1. A frame for stretching and holding papers, tracings, or other matter for the purpose, as described, of photographic printing or copying. 2. An indiarubber or its equivalent air or fluid pressure cushion or bag, for the purpose of pressing sensitive paper against tracings or matter to be copied or photographically printed. 3. A pad made thick at the centre and tapered away on all sides, of felt or other suitable material, for use with apparatus for photographic printing, or copying tracings, or other matter. 4. The use of a card-board, wooden board, or its equivalent, for the purpose of holding and pressing sensitive paper against tracings or matter to be copied or photographically printed, in combination with a suitable apparatus for stretching and holding the same, as described. 5. The use of a drawing-board or other board in combination with means for holding the tracings or matter to be photographically printed, as described. 6. The general combination of parts forming my improved apparatus for photographic printing, substantially as shown and described.

[Doubtless, the patentee is not aware that air cushions in the printing frame, for the purpose of keeping the paper uniformly pressed against the negative, have been in use for many years—nay, they have since thirty years ago formed the subject of patents, none of which, so far as we recollect, are now in force.—Ed.]

IMPROVEMENTS IN INSTANTANEOUS SHUTTERS FOR PHOTOGRAPHIC APPARATUS AND THE LIKE.

No. 18,150. EMILE TOURTIN and LOUISE PARSY, 8, Boulevard des Italiens, Paris, France.—*November 2, 1889.*

OUR invention is based on the observation of the following principle, the application of which by us is, we believe, entirely novel:—

If an opaque screen of any given shape is placed in sufficient proximity to a photographic lens, either in front of, at the back of, or between the system of lenses, like a diaphragm, the formation of images at the focal plane is not altered in any way; the sharpness remains as perfect, the luminous intensity only being reduced in the same ratio as that of the surface of the opaque screen to that of the lens.

If the screen so interposed in the direction of the luminous rays be in the shape of a grating, that is to say, with alternating plain and hollow parts, the above-mentioned fact will occur. In effect, the light rays emanating from an object situate at any distance greater than the focal length of the lens are in no way checked by the interposition of the grating, and are refracted in exactly the same manner as if there was no obstruction; the light rays striking against the plain parts of the grating are, it is true, lost, but the image remains quite as sharp although it is less brilliant.

If another identical grating is placed in front of the former one, the plain parts of one corresponding to the hollow parts of the other, and is made to slide against it, it will, at both the beginning and the end of the journey, act as an obturator, and meanwhile the openings of the fixed gratings will have been gradually opened and shut again, the greatest amount of light being admitted when the openings of the two gratings exactly correspond with each other.

If this apparatus is adapted to a lens placed in front of a camera, and is operated, the usual luminous impression will be obtained at the focal plane, with this advantage, that, as the displacement of the moveable grating may be made as short as desired by multiplying the number of bars, the duration of exposure is proportionately reduced and can be made to correspond to almost absolute instantaneousness.

But such a shutter, absorbing a great proportion of the light (a minimum of one half in the theoretical supposition of the bars and the hollows being of equal widths), could only be used for photographic purposes in the case of an exceptionally intense light being available. The same reasoning applies to a shutter with bars and hollows radiating from a centre, but the latter offers this disadvantage, that the central rays of light which are the more important would be intercepted.

The arrangements described would prove very suitable for photographic purposes if the substances used were of a sufficient degree of sensitiveness; but with the materials actually to be obtained in the market, we construct our

shutter with a series of parallel blades similar to those of a venetian blind, and which are acted upon by means of an appropriate mechanism; they turn together of a same angular motion and without losing their parallelism.

Each blade is mounted on two pivots, one at each end, lodged in the casing of the camera, and also provided with a pinion. All these pinions are in gear with a toothed rack, the forward and backward motion of which causes all the blades to simultaneously turn in one direction or in the other. The motion of the blades could equally be obtained by means of mechanical arrangements of any other description, such as pulleys and tape or string, articulated levers, &c.

If the rack or rod is pushed home in one direction, the blades are all closed, and a spring catch maintains the shutter so constituted closed until it is released by means of the ordinary pneumatic india-rubber ball, or any other contrivance; at that moment the rack or rod is shot to the other extreme position by means of a spring provided for the purpose. In the interval the shutter has been opened and shut again.

The tension of the spring and the consequent degree of instantaneousness which it is desired to obtain may be regulated at will by means of a thumb-screw, and is indicated on a dial by a pointer following the motion of the regulating thumb-screw.

The angular motion of the blades is about 180 degrees; they overlap each other so as to constitute a perfect obturator, and their number may vary from one single one to any number.

When the shutter is arranged to act in a vertical direction, the spring may be dispensed with if the weight of the rack or rod is sufficient to ensure the working of the system: the action of gravitation may even be retarded, if found too quick, by means of a brake or friction piece, dash pot, &c.

The shutter may be fixed in front or at the back of the lens, or even between the system of lenses; it is set in the centre of the apparatus by means of three set screws.

It will be readily understood that in our system of shutter the quickness obtained is greater than with the guillotine, either single or double, horizontal or vertical.

In the latter case, in effect, the light acts, at the same moment, upon the totality of the sensitised plate; small at first, it gradually increases to gradually decrease again, and the motion of the object to be photographed affects the plate from the beginning to the end of the exposure.

With our shutter the plate is only gradually affected, the luminous beam travelling in a direction opposite to that of the blades; the said beam is wider or narrower according to the distance between the blades and the width of the said. Consequently, should the width of the beam be equal to one half of the height of the sensitised plate, the same quickness as that obtained with a guillotine shutter will be obtained with our blade shutter in half the time.

Another advantage of our system is that its speed remains constant whatever the size of the lens, as the blades always travel the same distance.

As to the amount of light intercepted by the blades it is almost insignificant, not exceeding the proportion of about one in thirty.

Our shutter is applicable to other apparatus, such as magic lanterns, projection, and other apparatus intended for the instantaneous sending or receiving of beams or flashes of light.

What is claimed is:—The construction of an obturator or instantaneous shutter, for photographic or other purposes, and made of a series of revolving blades, substantially as set forth and illustrated.

IMPROVEMENTS IN AND CONNECTED WITH PHOTOGRAPHIC CAMERAS.

No. 18,403. PAUL JULIUS GUITON, I, Boulevard St. Denis, Paris, France.—
November 2, 1889.

With portable photographic apparatus, such as those used by tourists, there is always a difficulty in the replacing of the sensitive plates after each operation. This replacing takes some time and is somewhat difficult.

Now the object of my invention is to construct a multiplex sensitised plate carrier in which the changes of the plates can be quickly and readily effected. For this purpose I employ a frame divided into any suitable number of compartments, in which the sensitised plates or glasses are lodged. These compartments are uncovered in succession by an endless band furnished with slips of wood. A part of the surface of this band equivalent to that of one compartment is cut out, and at this place it carries the dark chamber. The dark chamber follows the movement of the endless band, and is therefore put in communication with each sensitised glass in succession; it is separated therefrom by a shutter which is drawn out at the time of the operation. At one of the sides of the frame I form opposite each compartment a notch, with which a small rod or stud fixed to the dark chamber engages. The chamber is thus guided to the proper position at each change, and its stability is ensured during the operation.

It will be understood that I can double the frame and have two rows of sensitised plates, and cause the dark chamber to turn around the frame; or I can give a rectilinear movement to the band and have any desired number of compartments; or the frame can be fitted to a fixed dark chamber, and in this case the frame would move.

The claim is:—A multiplex sensitised plate carrier constructed substantially as hereinbefore described for the purpose set forth.

A PHOTOGRAPHIC Society, to be called "The Blackpool Photographic Society," and which will hold its meetings at the Adelphi Hotel, Church-street, Blackpool, at Eight o'clock in the evenings of the first and third Tuesday in the month, has been formed in that town. The officers are as follows:—*President*: Alderman John Bickerstaffe, Mayor of Blackpool.—*Chairman of Committee*: Mr. Samuel Beverley.—*Committee*: Messrs. F. Gregson, T. S. Thompson, J. Wright, M. G. Wilde, W. H. Terry, D. Mitchell, and S. Beverley.—*Treasurer*: Mr. Isaac Wilde.—*Secretary*: Mr. S. Wolstenholme, Wellington Studio, Blackpool.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

NOVEMBER 26,—Mr. Chapman Jones in the chair.

Mr. A. Dawson, of the Typographic Etching Company, showed a number of works similar to those which had figured in the recent exhibition of the Society. They were mostly of rather warm tone, not unlike that at one time common with silver prints on salted paper. The negatives of some of the prints shown had been made with orthochromatic plates and a yellow screen, and he had been surprised at the remarkable efficacy of this plan in bringing out the dark colours of paintings that had been copied in this manner. The plates had all been worked upon before printing, either with the graver and burnisher or by protecting certain portions and biting in other portions more deeply with acid. It would be possible to produce plates which would serve without this manipulation, but in that case the relief would be low and the plate would not stand the wear of printing off, say, five hundred copies. There was some copper known as French, which was somewhat harder and would stand rather longer than that used in England, but in any case if many impressions were wanted the plate must be bitten in deeply in places.

Mr. LEON WARNERKE inquired where a yellow screen had been used, and being informed that it was in connexion with the lens, asked if definition was not thereby seriously interfered with.

Mr. DAWSON replied that definition was somewhat injured, but for the class of subjects in question not seriously so.

Mr. WARNERKE said that the best plan was to use coloured illumination. He employed a magnesium lamp with a glass front. This glass could be coloured of any required depth. Another advantage of using this lamp for copying, was that by placing it during half the exposure on one side of the picture and for the other half on the other side, the unevenness of surface did not show. Thus a paper with folds and wrinkles might be copied without these irregularities being visible. Another advantage of the lamp method was that a definite exposure could be given, independent of the fluctuations of the weather. There were some points of novelty contained in the lamp which he would bring to the next technical meeting of the Society. Had Mr. Dawson encountered difficulties with those caverns in the copper which were so troublesome in etching processes, and which he (Mr. Warnerke) had found especially vexatious, and to what cause would he attribute them?

Mr. DAWSON said that sometimes they were due to holes in the negative, sometimes to holes in the copper, but generally to cracks in the gelatine.

Mr. WARNERKE said that in Vienna copper deposited by galvanic action was principally used for photo-etching work. He had heard that sometimes there were particles of iron in English copper, which would account for holes being formed. It was also a fact that English brass wire was not so good as that made abroad; after a short time it became so brittle as to break readily.

Mr. J. A. HARRISON remarked that Bristol brass was much better in that respect.

Mr. ATKINSON inquired whether paraffin lamp light had been used for picture copying to produce orthochromatic effect.

Mr. WARNERKE replied that it had, and was very good, but for extreme cases was not yellow enough unless screened by a coloured glass.

Mr. Harrison showed us an historical curiosity, a Latimer Clarke stereoscopic camera, with one lens and moving camera.

Mr. Friese Greene produced some photographic prints by Victor Selb, of Antwerp. They were understood to be developed prints upon an emulsion containing starch. They were mostly of a nearly matt surface, but one or two were glazed. They were remarkable for the brilliancy and completeness of gradation in the shadows, being, as was observed by some of the members, the most perfect examples of deep gradation in prints without glazed surface that had been seen.

Mr. Montefiore then handed round some prints on albumen paper and one on salted paper, toned by Mr. Lyonel Clarke's formula containing chloroplatinate of potassium.

It was announced that the next technical meeting would be held on the fifth Tuesday in December—the 31st—as the fourth Tuesday would be Christmas Eve.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 21,—Mr. J. Nesbitt in the chair.

Mr. Kerr showed his detective camera, to which some improvements and additions had been made since it was last exhibited. The camera is one of the kind in which, after each exposure, the plate (fitted in sheaths) is drawn up by hand through the thickness of a cloth bag and placed at the back of the supply. The action of opening the lid was made to work simultaneously upon

movements that covered the plate, and drew it partly up so that it could easily be reached by the fingers, and that then set the shutter ready for use. Another improvement was that there was a blank or dummy sheath at the back of the set of plates (eighteen), and that this dummy was made so that it would not lift by the opening of the lid. The operator was thus informed that the plates had all been exposed and there was no danger of repeating exposures upon plates already used.

It was asked whether there was not a tendency to dust spots in cameras where the plate had to be manipulated through a cloth bag, and it was replied that in the present camera the cloth was of waterproof material with the rubber side in, and that no dust from the cause suggested had been observed.

The CHAIRMAN, noticing that the opening in the lens appeared to be large, inquired what was the ratio, and being informed that it was $f/5$, No. 24 on the universal system, said that anything larger than $f/16$ was useless for general views.

Mr. KERR replied that he had got very good results with $f/8$, and Mr. W. E. DEBENHAM recalled some very effective instantaneous pictures in the wet collodion times, when, generally speaking, no smaller openings would be practicable for such work. This referred especially to small pictures.

Eikonogen having been announced as a subject for the evening's discussion, Mr. A. COWAN said that he thought that eikonogen was destined to be as far in advance of hydroquinone as hydroquinone had been said to be in advance of pyro. It developed with a minimum of alkali, kept very well in mixed solution, and gave good colour; especially esteemed for lantern slides. It also gave the fullest detail without staining the plate, a result very liable to occur when using pyro and pushing development to the utmost.

Mr. W. COLLES remarked, with regard to the absence of staining, that the same thing was true of pyro when sulphite was used. He queried whether without sulphite there would be any advantage over pyro similarly treated. As to the quantity of sulphite generally recommended to be used with pyro, he thought it too great. With four parts sulphite to one of pyro, there was liability to excessive density in the lights, the details of which were thereby lost. He preferred two parts of sulphite, sufficient to prevent staining of the fingers.

Mr. J. H. B. WELLINGTON remarked upon the different qualities of the water found in certain districts, as affecting the character of the negative unless allowance was made. With soft water two parts of sulphite to one of pyro was sufficient in the constituents of the developer.

Mr. COLLES said that in one town he had developed plates without adding alkali. There had been some alterations going on at the waterworks, and there was sufficient lime in the water supplied to develop with the pyro.

Mr. ARCHER CLARKE said that when hydroquinone first came out he was not prepared for the length of time required in developing. The first plate put in the solution took a quarter of an hour to develop, and each succeeding one longer, until the sixth plate, which required an hour and a quarter.

The CHAIRMAN remarked that he could not have patience to rock plates during such long exposures, and if they were allowed to remain without rocking they became mottled. If a plate was developed in the light, the separation of the developer into mottled shapes similar to those seen on the developed negative could be observed.

Mr. CLARKE suggested turning the plate over to prevent mottling.

Mr. HADDON suggested that a vertical position of the plate would prevent mottling.

Mr. COWAN said that mottling took place with plates developed upside down. In one of a set of experiments that had been previously described, he had developed a plate in so weak a solution that it took fifteen hours. He had put the plate upside down in a basin, on the sloping sides of which the corners rested, but mottling had ensued. As to the new white eikonogen, he found that the solution after mixing did not oxidise so freely as with the original kind.

Mr. DEBENHAM inquired whether any member had had experience with the form of eikonogen developer recommended for insufficiently exposed negatives, both with and without the preliminary bath of mercury.

Mr. COWAN had noticed that with the latest issue of eikonogen the mention of the preliminary bath had been omitted. He had not found any advantage when using it.

Mr. TRAFF showed a transparency which had been intensified with uranium, and in which after an hour's washing the deepest shadows had become thinner, indeed, than the next tone.

Mr. DEBENHAM said that the deposit resulting from uranium intensification was slightly soluble, and therefore the process was not suited for gelatine negatives where a long washing was a necessity. With the thin film of collodion, which might be washed in a minute or two, the uranium process might be successfully practised.

CAMERA CLUB.

NOVEMBER 21.—Mr. Lionel Ashburner in the chair.

A paper, entitled *The Progress of Hydroquinone*, was read by Mr. A. MASKELL. The lecturer reviewed the advances made by hydroquinone in the past year. His own view of it was that, although pyro and ammonia was the more effective developer in the hands of the thoroughly practised, highest class of workers, hydroquinone proved a safer means of development for those not so highly trained in observation and practice. He considered it an advantage to be able, under some circumstances, to have one developer which would serve for negatives, transparencies, and bromide paper equally. Hydroquinone was found to be capable of this general use. The lecturer also exhibited samples of hydroquinone, and gave formulae and other practical notes, pointing out that hydroquinone might be found especially useful in enlarging, by first of all soaking the bromide paper in the developer and then exposing it wet for the enlargement. This would permit of examination of the print as the exposure proceeded, and local development or restraint would be possible.

Amongst other objects handed round in illustration of the lecture, were a series of negatives carefully tabulated and prepared by Mr. Swan (Messrs. Mawson & Swan), and a collection of excellent stripping-film negatives taken and developed by the Chairman (Mr. Ashburner).

In the discussion, Messrs. Stroh, Davison, Elder, Clark, Major Nott, the Chairman, and others, took part.

On Thursday evening, December 5, Mr. A. Horsley Hinton will read a paper entitled *The Standard of Excellence in our Art*.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

NOVEMBER 19.—Mr. G. J. Clarke in the chair.

Mr. J. Martin was elected a member.

It was decided to hold the annual dinner of the Society on January 21, and also to form a library.

Mr. A. MACKIE then gave a short explanation of the working of the optical lantern, and some excellent slides were afterwards exhibited on the screen, including a series of flowers by Mr. J. Carpenter, the negatives of which were taken on Edwards's isochromatic plates, the transparencies being on Thomas's lantern plates developed with eikonogen. The following formula was used:—

Eikonogen	1 ounce.
Sulphite of soda	2 ounces.
Water to make	50 "

Alkali:—

Caustic potash	1 ounce,
Water	10½ ounces,

one drachm of the alkali being used to each ounce of the eikonogen solution. Other slides were also contributed by Messrs. Mackie, Healy, Clarke, Brickdale, Purton, Powell, Walker, Grover, Coventon, Reader, Few, and Collins.

The next meeting will be on December 3, when Mr. W. Bishop will read a paper on *Lantern-slide Making*.

WEST LONDON PHOTOGRAPHIC SOCIETY.

NOVEMBER 22.—The President (Mr. Charles Bilton) in the chair.

The evening was devoted to the exhibition of members' slides by means of the lantern.

The SECRETARY announced that Mr. Stein would read a paper on *Hand Cameras* at the meeting of December 13. Those interested in the subject are invited to attend.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

NOVEMBER 15.—Mr. H. Banks in the chair.

Mr. E. Orme was elected a member.

Mr. MATHICE HOWELL gave an address on *The Early History of Photography*, illustrated by specimens of Daguerreotype and a large number of Talbotype executed by himself many years ago.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 14.—Annual meeting.—The President (Mr. Paul Lange) in the chair.

The SECRETARY read the annual report, after which the TREASURER read his statement of accounts, both of which were adopted.

The following officers and members of the Council were elected for the ensuing year:—*President*: Mr. P. H. Phillips.—*Vice President*: Mr. H. H. Williams.—*Council*: Messrs. H. Lupton, H. Wilkinson, T. S. Mayne, F. N. Eaton, W. Faltin, F. Hope-Jones, J. L. Mackrell, and Paul Lange.—*Auditors*: Messrs. A. Bradbury and G. A. Carruthers.—*Librarian*: Mr. J. A. Forrest.—*Treasurer*: Mr. E. M. Tunstall.—*Secretary*: Mr. C. B. Reader.

The awards made by the Judges in the annual competitions for 1889 were then read by the President:—"For the best set of six pictures over half-plate," silver medal: Mr. J. L. Mackrell. "For the best set of six pictures under half-plate," silver medal: Mr. H. Wilkinson. "For the best set of six instantaneous pictures," bronze medal: Mr. H. Wilkinson. "For the best enlargement," bronze medal: Mr. J. L. Mackrell.

It was unanimously decided to have a social evening, one of the members (Mr. W. H. Hunt, Mus. Doc.) having kindly undertaken the musical arrangements for the same.

A lantern exhibition of members' slides then followed, some of which were of very high merit.

BRADFORD PHOTOGRAPHIC SOCIETY.

NOVEMBER 19.—The Rev. Dr. Aston in the chair.

The PRESIDENT (Mr. A. Keighley) gave his inaugural address on *Photographic Printing Processes*. Having explained the general chemical principles involved in photographic printing, he explained the special ones in silver, iron, and chromium printing. Various chemical experiments illustrative of the action of these salts were made, and specimen prints by each of the different processes were developed, &c., before the members. At the close of his lecture Mr. Keighley called attention to the prints around the room, which would represent the capabilities of each process he had described. These prints were of excellent artistic and technical finish, and were greatly admired by the members.

The Committee has decided to give a *conversazione* on Tuesday, December 10, at which an exhibition of members' work, microscopes, stereoscopes, &c., will take place. There will also be a lantern-slide exhibition. Members and their friends are cordially invited, and tickets and other information may be obtained from the Hon. Secretary (Mr. Walter Leach), 50, Godwin-street, Bradford.

WALLASEY PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 6.—Annual meeting.—The President (Mr. H. Wilkinson) in the chair.

Mr. WILKINSON, in his opening address, stated that the Association was now in its fourth year of existence, and had steadily increased in numbers and

usefulness, and the members had attained a higher standard of work, as would be seen by the pictures hung round the room which had been sent in for the annual prize competition.

The HON. SECRETARY reported that the membership roll showed an increase of one hundred per cent. since last annual meeting; that twelve meetings of the Association had been held, at which papers of photographic interest had been read and practical demonstrations of the various processes given. The winners of the medals were Messrs. J. L. Mackrell, H. Wilkinson, J. W. Gregg, J. Gill, and C. B. Reader.

The officers for the ensuing year were elected, and are as follows:—*President*: Colonel E. T. D. Cotton, M.P.—*Vice-Presidents*: Messrs. Edwin Kite and J. W. Gregg.—*Hon. Auditor*: Mr. J. Hardsley.—*Hon. Treasurer*: Mr. J. Fullerton.—*Hon. Secretary*: Mr. G. Bredding, Church-street, Egrement. With a Council of six members.

CHELTEMHAM PHOTOGRAPHIC SOCIETY.

NOVEMBER 7.

Captain HARRISON exhibited a collection of marine and other views which he had taken, the former in the Solent from the deck of a steamer in motion. Two of the photographs shown had only received an exposure of one-one-hundredth of a second, and yet all the details were perfectly brought out. The developer used was composed of—

Eikonogen	15 grains,
Soda sulphite	15 "
Caustic soda	15 "
Water to	1 ounce,

and Captain Harrison stated that he had found this developer coax out detail which would not show itself under any other developer he had tried.

Mr. Nash showed bromide prints which he had developed with a ferrous oxalate developer, the iron solution being composed of—

Ammonio-sulphate of iron	1 ounce.
Meta-bisulphite of potash	2 drachms.
Water to	5 ounces.

This solution to be mixed in the usual proportions with the oxalate of potash solution. The peculiarity of this developer is that it dispenses with the acid water wash after development, and gives a fine blue-black tone unattainable by the ordinary oxalate developer.

Mr. PARSONS handed round some cabinet portraits which had been toned in a borax bath, and in answer to a question as to how he managed to obtain such purple tones with borax, he said that he found the addition of half a drachm of strong liquor ammonia to one gallon of water, for the last washing before toning, enabled him to obtain the good purple tone noticed.

THE PHOTOGRAPHIC SOCIETY OF JAPAN.

SEPTEMBER 27 (at the Masonic Hall, Yokohama).—The chair was occupied by Lieutenant Bull. The meeting was of a technical character; that is to say, it was for the purpose of exhibiting anything that might be considered in any way new in connexion with photography in Japan.

The following gentlemen were elected members of the Society: Messrs. Kusaka, M. Nakashima, B. Hayashi, B. H. Pearson.

After some formal business had been concluded, Mr. Kajima exhibited several cameras of English design and Japanese manufacture. These were cheaper than the corresponding English cameras, and the workmanship was generally pronounced to be very creditable.

Mr. K. Ogawa showed some remarkably fine collotype prints, and briefly described the process. The printing is done in a press directly from a plate that has been prepared with a sensitive surface of gelatine and bichromate, and that has been exposed under a negative. The parts that have been insolated will take a fatty ink, the others will not, and it is thus possible to ink up the plate and to draw proofs from it. Several hundred proofs can be drawn from one plate, and an indefinite number of plates can be made from one negative.

Mr. C. D. West showed an arrangement that he had designed for taking photographs of one boat from another. The arrangement consists essentially of a bracket that can be fixed to the main or foremast of a sailing boat, and a universal joint with arrangements for holding a camera which may be aimed at any object, and caused to follow it till an exposure is made. Some examples of photographs taken by the aid of this apparatus were shown.

Mr. W. K. Burton showed silver prints made on Whatman's drawing paper and on very thin Japanese paper. The process consists in coating the paper with an emulsion of resin and gelatine, in which is dissolved a small quantity of a soluble chloride. The paper is then dried, and is sensitised with an ammonio-nitrate of silver solution, the sensitising being twice repeated in the case of the drawing paper.

Mr. Kajima showed some Japanese fans which were decorated with photographs produced directly on the paper of which they were made. These were much admired.

Messrs. Cocking & Co. sent a large and interesting exhibit of lenses and other photographic apparatus. Amongst the things shown were a very fine camera by Meagher & Co. of London, and lenses of Suter and of Dallmeyer, the latter including several of the new "rectilinear landscape lenses."

Mr. Konishi showed a sample of the new developer "eikonogen," and the CHAIRMAN promptly ruled that it should be appropriated by the Society, and that certain members should be appointed to experiment with it, and to report to the Society on the results of the experiments.

Messrs. K. Ogawa and W. K. Burton were instructed to undertake the experiments.

The meeting concluded with a vote of thanks to the lender of the hall and to the Chairman.

The next meeting will be held on October 13. It is to be a camera field-day, and the place selected is Kamakura. No particular hour is fixed, as it is hoped that some will be able to come early in the morning, and there is no reason why camera work should not be kept up through the whole day. Probably some members will extend their trip to Enoshima.

Correspondence.

Correspondents should never write on both sides of the paper.

ELECTRIC LIGHT IN THE LANTERN.

To the Editor.

SIR,—My only reason for any reply to Mr. Baker's letter is that, if I make none, some of your readers may gather from it that there are difficulties which really do not exist in availing themselves of a light which, for those who have current available, is singularly handy and convenient for making enlargements. To take size first, my own lantern is large enough as it is; but if it were not, surely it would never occur to any one but an optician to build another special lantern, when it is so easy to remove the slide-tray and elevate the lantern on some little wooden base. Of course, if any one is buying a new lantern and all, he would have it an easy size; but people need not and should not write of "special" lanterns for such ABC matters as this, as if there were real difficulty to be overcome in using this light.

I have been pretty familiar with electric lights of all sorts for years past, though my efforts have chiefly been directed to finding a perfectly steady arc light with only one luminous point, in which I am glad to say I have succeeded. Hence I was not so much surprised at the heat of a 100-candle incandescent lamp, as Mr. Baker appears to have been. But I do not consider the radiation so great as that of an 800-candle jet which I use at times; and there need be no fear of it in any lantern with proper space and ventilation for an oxy-hydrogen jet. The lamp is hardly likely to be used in a binnial, but is essentially a single-lantern light; and it is also to be remembered that, as there is no combustion and no ascending vapour, but simply radiation, the lanternist can open and alter his top or his chimney in any way he likes with no difficulty. The whole matter would be a case of *soloitur ambulando* with any one of common intelligence. We do owe, I am glad to learn, to Dr. Fleming credit and thanks for inducing the Company to put on the market an optical lamp made on the grating system—but that being done for us, the object should be to spread knowledge of the convenience, and not to hedge it about with difficulties that do not really exist. Few would have gathered from Mr. Baker's first letter that the light could be got by any one from the vendors for a few shillings, or otherwise than by purchasing a "special" lantern and apparatus from Messrs. Steward.

London, November 22.

LEWIS WRIGHT.

FOG ON DRY PLATES.

To the Editor.

SIR,—May I be permitted herewith to thank Mr. Lyonel Clarke for his communication to THE BRITISH JOURNAL OF PHOTOGRAPHY of the 15th instant, on *Another Cause of Fog on Dry Plates*?

Curiously enough, the day after reading the above I was asked to examine a number of negatives taken by a gentleman in the country. It appeared they were very unsatisfactory, would not print, &c., and he was beginning to think "Photography a failure."

They certainly were all badly fogged, and as the exposures, developer, and dark-room lamp ("perfection") were all seemingly correct, I was puzzled to account for the cause. Then, suddenly remembering the article in your JOURNAL, I asked to see the camera, and there, sure enough, were several patches of green mould, about one cubic millimetre square.

These were then immediately removed with a dry cloth, and we went out and made several exposures, and developed in same manner as before. The results were entire freedom from fog; and so I think, with Mr. Clarke, that all will do well (especially this damp weather) to examine camera interiors very carefully and keep them in a dry place.

As to the action of the fungus on the sensitive salt, I am divided as to opinion at present. That it acts most powerfully and instantaneously I have found by a few experiments. I rather incline to the notion that mildew possesses luminosity, which, though practically invisible, is highly actinic, probably down to the ultra-violet end of the spectrum. Many fungi are distinctly luminous; touchwood, for instance, which is wood eaten up by the mycelium of fungoid growths, is so. Further, is it not a fact that a magnet is photographable by a light it emits? also a boiling kettle? Well, as the boiling kettle is to the red end of the spectrum, so, I have an idea, is this fungus luminosity to the violet end.

I should be deeply gratified if such great experimentalists as Captain Abney and others, with their vast resources for conducting experiments, would investigate this matter, and let us have the benefit of their experiences.—I am, yours, &c.,

A. HOWARD BENHAM.

66, Wigmore-street, W., November 25, 1889.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—Mr. W. Durrant says he has read my letter, but he seems to have forgotten that I therein profess to be but an indifferent worker with the

* This because I could find no traces of any spores on the film with the microscope.

camera. He further says that when he has seen my work he will be better able to determine whether my criticism of Mr. Robinson's is worth consideration.

If I grant, for argument's sake, that my photography is altogether bad, what has that to do with my opinion of other people's? Without being able to make a sovereign, I may know one from a counterfeit coin when I see it. Unless he proves that I have made statements which are not strictly and altogether true respecting the works of Mr. Robinson, his letter, I think, will have no value in the esteem of unprejudiced readers. If I have said of them what is true, then they have no claim to be considered works of art. Did an artist ever paint a picture in which different objects therein are represented as throwing sun shadows in different directions? And would a painter who did so be regarded as an artist by any one possessing common sense, to say nothing of artistic knowledge and feeling?—I am yours, &c.,

The Arts Club.

BARR. ROUS.

PROPOSAL FOR A NATIONAL PHOTOGRAPHIC UNION.

To the Editor.

SIR,—I enclose a copy of Resolutions unanimously adopted at the last meeting of the North Surrey Photographic Society.

I may say that these Resolutions are the outcome of deliberations of some months past amongst our members, which have assumed a more definite form, owing to the notice of the Society being called to a proposal in circulation for an institute founded on lines strongly objected to by the members.

At present there exists no body representative of photographic interests to be consulted either for legislative or other purposes.

As examples of the utility of such an Union, attention need only be directed to the great advantages derived from similar bodies at present existing in the Angling and Cycling worlds.

With a view of convening in London a preliminary meeting, all those willing to co-operate in the movement are requested to communicate with me at 369, Norwood-road, S.E.—I am, yours, &c.,

J. LARCOMBE, Hon. Secretary.

I. At a meeting of this Society, held on the 19th November, 1889, it was resolved that it is desirable to found a National Photographic Union, so constituted as to fairly represent all photographers in the United Kingdom. The object of such Union being to benefit photographers and all those connected with the art by watching over their interests generally; and being made representative by inviting every society to send delegates to sit on its Council. The scheme of its work to be drawn up by the delegate representing the societies.

II. That the foregoing Resolution be forwarded to the Photographic Press and the Photographic Societies; and that the latter be requested to give their opinion on the question, and to say whether they are prepared to co-operate in forming such an Union.

A PHOTOGRAPHIC BLUE BOOK.

To the Editor.

SIR,—I am glad to be able to throw some light on the authorship of the book described by Mr. William Lang, jun., in your issue of October 25, to which my attention has just been directed.

"A. A." were the initials of Mrs. Atkins, who lived for many years at Halstead Park, Kent, and died there in June, 1871. She was the daughter of Mr. John George Children, Assistant Librarian (i.e., keeper of the zoological department) of the British Museum from 1816 to 1839. On his retirement he lived with his daughter at Halstead; he died January 1, 1852, and a memoir of him by Mrs. Atkins was privately printed in 1853. Mrs. Atkins had a large collection of British plants, which, at her death, was bequeathed to the British Museum, and is now incorporated in the British herbarium there. She also collected a little in Normandy.

We have also, in three volumes, each prefaced with title and list of species, the collection of cyanotype impressions described by Mr. Lang. The first volume contains one hundred and sixty-two plates, the second one hundred and fifty-one, and the third ninety-eight, making a total of four hundred and eleven, as against three hundred and seventy-seven in the series seen by Mr. Lang. The interesting prefatory matter quoted by Mr. Lang does not appear, except the last paragraph, which stands at the foot of the Appendix to the third volume; it is followed by a page of "errata." The date in our copy is, I think, "1853," not "1859" as given by Mr. Lang.—I am, yours, &c.,

JAMES BRITTON.

Department of Botany, Natural History Museum, Nov. 22, 1889.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—Perhaps you will allow me to say a word or two on this vexing question. Time was when the greater number of amateurs were wealthy men with leisure, who found in photography a congenial occupation in one or other of its branches—scientific or industrial. Now the "cheap set" trade has opened the way to the multitude, and instead of having to reckon with a gentleman, the professional of to-day has very often to put up with the impertinences of a snob.

The following short dialogue may be taken as a type of what often occurs in the middle of a business day.

Enter "cheap set" man, after long inspection of your specimens. "Aw not a bad thing that of—; what time of the day did you get it? I am photographing about here, don't you know. Down for my holiday. I am in one of the departments of the Customs. I have got some splendid pictures. Do you mind developing a few negatives for me? Whose plates do you prefer—developer, lenses, cameras?" &c.

You get rather riled to hear your picture, which may have cost you a long hunt to get, called a "thing," but your usual courtesy to a brother-photographer holds you back, and you probably end by giving up your dark room for a couple of hours to the upsetting of all your own business system, and probably one or two stock bottles.

By-and-by you are repaid by seeing a series of caricatures of your best work appear in the shop window as cheap opals, or in the guise of birthday cards, and these you recognise as the work of your amateur friend. I presume your correspondent, J. Storey, would call this "honest labour, to put bread and butter into the mouths of his family;" and he would say to the professional, "Providence has not intended you for the vocation. Go, seek work of another kind." Oh, Chadband! But, you see, these public offices are not open to us yet.

I must take exception to the statement that professionals have done little to perfect the art. Why, the journals for the last thirty years teem with the experiences of the best workers—experiences which it is the fashion nowadays to dig up and serve as a new discovery by your trading amateur.—I am, yours, &c.,

LINTERN.

To the Editor.

SIR,—Since this discussion upon the amateur question has waxed so warm, there have been many hard things said on both sides. There have been some capital common-sense letters. Your correspondent indeed must strike a tender spot in the consciences of some of our professionals. I say advisedly "some," for, thank goodness, they are not all alike. Are not almost all inventions in photographic matters originated by amateurs who give not only their money, but the best years of their life, to the advancement of the engrossing art-science? And who benefits by the inventions of amateurs? Why, professionals, of course. They do not even try to perfect or improve upon a process, but simply wait until the whole process is published in detail with the latest improved formulae. I cannot but think that the root of the bitter feelings that are expressed towards amateurs is attributable principally to jealousy, for many professionals turn out work which would put to shame a second year's amateur. Professionals should not fear much harm at the hands of amateurs, for, as a rule, the most he can get in the way of remuneration is "costs out of pocket." Then how can professionals expect that dealers are going to help them to "squash" the unfortunate amateur? Where would eight out of ten of the dealers be if it were not for this class of man, whose every photograph, I might say, costs him treble what he could get one professionally taken for, because he is not satisfied with the colour of this or the density of that; or the picture when mounted looks unimportant, and should have been mounted on a "plate-snuk" mount or a plush one? Then he must spend more money in repeating the print and getting another frame. If the professional can only swallow his petty jealousy and acknowledge the truth, he would say that the amateur is "not quite so black as he has endeavoured to paint" him.—I am, yours, &c.,

London, N.W.

FREDK. W. MUNCEY.

To the Editor.

SIR,—A correspondent suggests that in order to do away with the amateur difficulty, that the four developing agents—pyro, oxalate of potash, quinol, and eikonogen—should be highly taxed. For some reasons, perhaps, this might be a desirable thing, inasmuch as it might prevent amateurs aiming so much at quantity at the expense of quality. But would it not affect the professional quite as much as the amateur, especially considering the number of positions they are in the habit of taking one in nowadays? Your correspondent must also have overlooked the fact that the developer is, after all, only one of the minor items of expense.—I am, yours, &c.,

A. F. JONES.

The Lindens, St. Leonards-on-Sea.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange quarter-plate set, complete, for half-plate camera or set, complete.—Address, K., 189, Southampton-street, Reading.

James's triple flash lamp, good as new, in exchange for whole-plate printing frames.—Address, J. DAVIS, 31, Cambridge-road, Barking, Essex.

A Boston Humber tripper tricycle (suit either sex) offered in exchange for a light 15x12 camera and lens.—Address, PHOTO, Museum-parade, Matlock Bath.

Good head and body-rest, a metal chair ditto, office copying press, half-plate box, camera, and back; want shutter and tripod.—Address, W. C. CHIFFIN, 39, Highgate-hill, N.

Ross's wide-angle stereoscope lens; will exchange for half-plate camera, two or more double dark slides, reversible back.—Address, BROS & SON, Chemists, &c., Halstead, Essex.

Double lantern objective of large diameter wanted in exchange for three-draw telescope, one and a half inch object glass.—Address, GRANGER, Photographer, Rotherham.

Wanted, posing chair with two or three backs; will exchange portrait lens by Pain, of Cambridge, eleven inches focus, lenses three and a half inches diameter. Wanted also, some 15x12 or 12x10 dishes in exchange for portrait lens, six and a half inches focus, lenses two and a quarter inches diameter.—Address, FELLOWS, Old Court-house, Enfield Town.

Answers to Correspondents.

* Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

G. W. Webster, Chester.—Two photographs of Master Taylor.

P. S. Lankester, Tunbridge Wells.—Two photographs of group of shooting party.

AULD REEKIE.—1. In Japan only, we believe.—2. Write to Liesegang, Dusseldorf; he will, no doubt, supply the article needed.

WOODPECKER.—One lens will have nearly double the rapidity of the other, supposing both to be worked with their full aperture.

WILTS.—The marks on the two plates are due to the coating. Evidently they were coated by machinery which was out of order at the time.

P.—For general cabinet work the No. 2 of the maker named will prove more useful to you than his No. 3. The 5p will serve for the larger heads.

INSTANTO.—The only secret in taking first-class instantaneous pictures is a quick-acting lens, a good light, a very sensitive plate, and a rapid shutter.

J. E. G.—The yellow spots appear to be sulphide of silver, caused by the hyposulphite of soda not having had equal access to all the surface during the operation of fixing.

TRANSFERO (York).—Yes. Bichromated gelatine paper can be printed by the electric light. Of course the arc light must be employed. The exposure will be somewhat long.

GEM.—1. Perforating machines are supplied by those who deal in printers' materials.—2. Paint the design required on a light frame with an opening, and suspend in front of the sifter.

49.—1. Neutralise the solution with carbonate of soda and then make it distinctly acid with nitric acid.—2. Yes. Better get the citrate of soda. Bicarbonate of soda is doubtless meant.

ALICE ROBERTS.—As we said in the article referred to, the paper is not at the present time an article of commerce; therefore, we fear, you will have to prepare it for yourself. This you can do according to the instructions given.

B. MOREY.—From a feeble negative which will not yield a bright silver print it will be impossible to obtain a good print by the platinotype process. Vigorous prints may, however, be obtained by using bromide paper, with care in the exposure and development.

A. B. (Wood Green).—The only method of recovering the platinum is to burn the paper and send the ashes to a refiner to be reduced; but unless you have a considerable quantity it will possibly not pay for the trouble. Platinum is a very refractory metal to deal with.

A. FRASER.—If you mean collotype printing, try the London Stereoscopic Company or Waterlow & Sons. We cannot give an estimate of the comparative prices in London or Paris, but we think this country will, as regards favourable terms, hold its own against others.

W. J. CARTER.—There is very little doubt about it. The marks or bands on the plates which have been kept so long in the slides are due to the leather or other material of the hinge. Better return the slide to the maker to remedy with fresh hinges of a different material.

S. C. BOYES.—The only suggestion we can make with regard to the "pyro solution which has gone bad" is to throw it away and make fresh. At most it did not cost more than a few pence. It is, as a rule, false economy to attempt to doctor any solutions which have become deteriorated.

A.—If the quantity of liver of sulphur added is not sufficient to precipitate the whole of the silver, more must be employed. You say the addition of "the liver of sulphur does not have the desired effect." If by this is meant that no precipitate is produced, then there is no silver in the solution to throw down. We do not remember what the previous query was.

LANTERN.—None of the ordinary four-inch condensers of commerce, at any rate, none that we have examined, will properly illuminate the corners of a slide the size of which measures a little over three-and-three-quarter inches diagonally. It would, however, be possible to construct a condenser that would do so, especially if the slide was placed very close to it.

W. BELL writes: "I have an old portrait lens by Voigtlander, which does not work to focus, but I have been told how much alteration to make after focussing. With such a lens, is it possible to take as good pictures as if its optical and visual foci were coincident?"—If the right adjustment be made—after visually focussing—all things being equal, quite as good results will be obtained.

VERAX.—1. We do not know where the Japanese varnish can be procured.—2. Full accounts of the Wothly method of uranium printing will be found in our volumes for 1864 and 1865. The Wothlytype process was worked commercially by the United Association of Photography, a company which ceased to exist more than twenty years ago. The prints were silver prints, the uranium acted merely as a species of developing agent.

G. KERSHAW.—The most successful block process is, perhaps, that of the Meisenbach Company. These blocks are well adapted for printing with type. The process is not published, nor, indeed, are the details of any of the most successful block processes. Collotype plates cannot be worked with type. The other process mentioned is, we think, a collotype. Collotype is worked under several different names by different firms. Obtain Mr. Wilkinson's book.

E. B. asks: 1. When gas cylinders are used is it more economical to work the mixed jet than the blow-through jet?—2. Is it quite safe to use the mixed jet with the gas in cylinders without pumice chambers or other similar contrivance being employed?—3. Is the safety of the jet affected by the gases being under different pressures?—In reply: 1. Light for light the mixed jet is the more economical.—2. Not if governors are used on the cylinders.—3. Yes; very materially.

GEO. CLEARY has been experimenting in albumenising paper, and sends some examples. He wishes to know the cause of the defects—streaks and want of gloss. He says he used pure white of fresh eggs only.—The streaks are due to the albumen not being sufficiently beaten. It should be entirely converted into froth, so that when the vessel containing it is inverted nothing will run out. Unless it is got into this state in the first instance unevenness must be expected. The lack of gloss is due to the paper. This appears to be a common sample of printing paper—not photographic paper—which has absorbed the greater portion of the albumen instead of retaining it upon the surface.

J. T. LEON writes: "I have a photograph which has been stuck on a sheet of glass and framed with a glass in front of it. Probably owing to damp, mildew has appeared on the surface, and also a number of yellow spots, going right through the paper. The photograph is a silver print on albumenised paper, and as it is a valuable one I should be glad if you could suggest any means of removing the yellow spots. They are like yellow spots which occur during toning and fixing."—Probably the print has been kept in a damp place, and the cement used in mounting contained mildew germs. There is no remedy. The best thing to do is to copy the picture and touch out the defects in the negative.

C. A. says: "I have just purchased a lantern with a three-wick lamp for paraffin oil. The light is fairly good, but the fumes from it are most unpleasant. Of course one expects this when the wicks are turned too high, but this lamp smells when the wicks are at the right height. Can anything be done to avoid this?"—A great deal depends upon the management of the lamp. The wicks must be kept trimmed perfectly even with the tubes. If there are projecting pieces smell is almost certain. The outside of the lamp and wick tubes should be kept scrupulously clean. Most of the smell arising from paraffin lamps is due to oil on the surface, which with the heat is evaporated, hence the unpleasantness.

DAVID GREEN writes: "Can you help me in explaining the nature of the spots on the enclosed prints? They have been shut up in the cigar-box, and have made their appearance during the last six months. It is quite impossible that any foreign matter could have fallen on them, as they have been locked up in a cupboard, and only handled by myself. Two distinct brands of paper have been affected alike, while prints from the same sheets of paper, not packed in the box, remain unchanged. The spots have formed apparently on the albumen side of the paper. The prints were not rolled together, but thrown in loosely in the box; about two dozen prints, every print spotted. I may say that I am a most careful worker, and have forwarded you the identical box in which the evil has taken place. If you can solve the mystery I shall be very grateful."—In reply: There is an exudation from the cedar-wood cigar-box in question, which would congeal in resinous globules on the prints; but there is, in addition to what the cedar itself is capable of, the further exudation from the essential oils with which cigar-boxes are impregnated and the cigars themselves frequently well sprinkled in addition, for the purpose of imparting Havana and similar characteristic flavours.

PHOTOGRAPHIC CLUB.—Subject for discussion, Wednesday, December 4, 1889, *Dark-room Appliances.*

Great Thoughts, a weekly journal which has much attracted our attention of late by the excellence of its portraits of famous men and women, no less than by its sound literary merits, is to commence its new volume by a serial story by Dr. Joseph Parker, of the City Temple, London.

RECEIVED from Marion & Co.:—*A Complete Treatise on the Art of Retouching Photographic Negatives, and Directions how to Finish and Colour Photographs*, by Robert Johnson. Also received:—*Revised Formulae for the Production of Transparencies on Cowan's Chloride and Chloro-bromide Lantern Plates*. A review of these will appear in our next.

A new society has been formed in Bolton under the name of "The Bolton Camera Club," to hold its meetings every Wednesday, at half-past seven p.m., at the Studio, 21, Bury New-road, Bolton. The officers elected are:—*President*: Mr. John Johnston, M.D.—*Council*: Messrs. Thomas Parkinson, sen., Jonas Royle, James Turner, Walter Russell, and Joseph Berry.—*Treasurer*: Mr. Jabez Boothroyd.—*Hon. Secretary and Librarian*: Mr. Thomas Parkinson, jun., 117, Westbrook-street, Bolton.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1544. VOL. XXXVI.—DECEMBER 6, 1889.

MEANS OF PRODUCING HEAT.

THE rather sudden advent of weather that is unusually cold prompts us to look at this from a photographic point of view equally as did a high thermal range several months ago.

Cold is altogether inimical to many chemical operations, in particular to those relating to photography, and one evening lately, when things were not proceeding in our laboratory as they ought to have done, it needed but a glance at the thermometer to indicate the cause. It is now axiomatic that all chemical action is aided by heat; and it is *per contra* retarded by cold. As cold may be produced by the admixture of certain substances, so may heat by means analogous. In a former article we showed in what way solutions which in a torrid climate acted prejudicially upon a sensitive plate when in course of development and subsequent treatment could be cooled down to any degree desired; and antithetically we now go on the opposite tack and show that by certain additions to water, whatever its temperature, a considerable degree of heat may be obtained.

The best of all substances for this purpose of which we are aware is happily also one of the cheapest. Out of its calorific properties arose a species of trick experiment known to all schoolboys who dabbled in chemistry. Having obtained a very thin glass bottle, half fill it with water and give it to a friend to hold firmly in his grasp; now pour slowly into it ordinary sulphuric acid. The effect will be that such a degree of heat will have been engendered, that long before the bottle has been filled the holder will have set it down.

The knowledge of this may prove useful to some who desire ready means of intensifying the action of either developer or fixing solution which have become sluggish, if not altogether inert, owing to their low temperature. We have tried both developing and fixing negatives by means of solutions of the excellence and certainty of action of which at ordinary temperature we were well assured, but which at the time of our trial had been suffered to fall to about two degrees above the freezing point. Chemical action seemed as if arrested. The solutions had been placed in two thin, flat dishes made of well-spanned tin ware, and each was placed in a larger vessel containing water. A few drops of sulphuric acid were now poured at short intervals into the outer vessel containing the water, and it soon began to tell upon the solutions in the trays, developing and fixing proceeding as when normal temperature prevailed.

We here throw out a suggestion that a small condensing tub having a worm composed of leaden pipe running through it might at times be found convenient by some who have no appliances handy for raising the temperature of any fluid—

spirit lamps, bunsen burners, or similar calorific appliances being assumed to be absent at the time—for by an admixture of sulphuric acid and water a considerable amount of heat could thus be obtained. The ingenious photographer will soon discover various ways in which to apply this system.

Some substances retain heat much longer than others. A few years ago a metallic case filled with acetate of soda and then sealed was much employed as a means of retaining heat for a long time, and numerous applications of it were suggested at the time. When immersed in boiling water for a time and afterwards taken out, it was found to retain its heat for a longer period than any other means hitherto tried. We well recollect at the time heating up a copper vessel filled with the acetate and afterwards transferring it from the boiling water to a small Norwegian stove to find that the day following it was still quite hot.

But there are other salts which are known to require, when in saturated solution, a higher temperature to raise them to the boiling point than acetate of soda, chloride of calcium surpassing it in this respect. The boiling point of the calcium salt is found to be 355° Fahr., which exceeds by nearly 100° that of the soda.

It is not, however, our intention to here enter into the domain of physics further than indicating as we have done a simple way by which the photographer, when other agents are absent, may be enabled to work successfully in even the coldest weather.

NEGLECTED PROCESSES.—BLACK VIGNETTES— DENIER EFFECTS.

THE above might possibly be classed as neglected styles rather than "neglected processes." Yet there was in each style a sufficient departure from the ordinary method of working to warrant both being alluded to in this article. Moreover, now that popular taste in photographs is undoubtedly undergoing a marked change, it may be worth consideration as to whether, if these were again introduced, they, the latter especially, would not meet with a certain amount of success commercially.

We shall first allude to the pictures of Bergamasco. About twenty years or so ago this Russian photographer exhibited in this country a novel style of portraiture. It was a large size vignettied head and shoulders, the head being some three or four inches, and sometimes even larger. The peculiarity in the pictures was that the figure instead of being vignettied into a white ground, as usual, was shaded into a black or nearly a black one. The lighting of these portraits was bolder and more vigorous than usual, so that the contrasts were strong and

forceful. Furthermore, the pictures were always mounted in dark and massive frames; hence the portrait itself looked exceedingly rich and brilliant. The negatives were said to be vignettied in the camera, therefore the prints were as readily produced as ordinary non-vignettied ones. Of course, the same result could be obtained by double printing, instead of taking a negative specially for the purpose. The principal features in Bergamasco's pictures were their large size and their force and vigour, to which effect the dark vignetting and style of framing largely contributed.

The Denier pictures were a decided novelty at the time they were introduced. They were of a somewhat large size, but the peculiarity in them is difficult to describe. There was a certain softness, or indistinctness, about them, yet if they were closely examined they appeared to be perfectly sharp. This characteristic gave them the appearance of being on porcelain rather than on paper. Perhaps the effect may be better described if we liken it to a picture made on the transparent side of a thin piece of flashed opal glass. The pictures were certainly very brilliant, and were generally admired for their artistic qualities. How they were produced was never published, that is to say, with the authentication of the introducer. It was a "secret process," and it was the intention of Denier to sell it as such in this country to a certain number of subscribers. But these were never obtained.

When the pictures were first shown, there were many suggestions as to how they were produced, several of which we shall now allude to. The method most credited as being that used by the originator was that two negatives, duplicates of each other, were taken and developed only to half the requisite density had they been used separately. These two negatives were then superimposed, the one upon the other, and the print made from the compound negative. Another suggestion was that the plate was sensitised on both sides with a thin film, so as to secure a sharp image on one side and an out-of-focus one on the other. One plan was that of making part of the exposure with the image in focus and a part with it out of focus, both backward and forward: for example, by giving half the exposure with the lens in focus, and a quarter with it racked a little inwards, and the remainder of the time with it a trifle outwards of the sharpest focus. By this means we at the time obtained results analogous to those of Denier.

Here is another method, and it answered well:—Make a portion of the exposure with the lens, a portrait combination, stopped down, and then remove the stop and finish the exposure with the full opening. This produced a pleasing effect, particularly if the lens possessed a considerable amount of spherical aberration. One proposition was to give a part of the exposure with the camera stationary, and a portion with it in a state of vibration. This was to be managed in the following manner:—A cord was strained from the camera to a rigid object, say the floor, and then, when part of the exposure had been given, the cord was put in a state of vibration by drawing a violin bow across it and the exposure continued. The interposition of a sheet of glass between the lens and the sensitive plate was also suggested.

The following method was used for producing these pictures, and it is one by which we have obtained results equal in every respect to those of Denier, while it has the advantage that any negative already in stock can be utilised:—The print is partly made with the paper in close contact with the negative. It is then removed, and a thin sheet of glass, or one or more thicknesses of transparent gelatine, interposed, and the printing

afterwards continued to the requisite depth. By varying the depth of printing with the paper in contact with the negative and the extent of the separation afterwards, any degree of sharpness or softness can be obtained at will. In America specially constructed printing frames were introduced for producing this effect. Those who essayed this class of picture when it was first introduced mostly confined their efforts to small sizes, and for these this style is certainly not well adapted. Its special province is that of large portraiture.

At the present time excessive sharpness—crispness—in large portraits is not so much sought after as it formerly was; therefore, if the Denier style of picture were now reintroduced there would be a fair prospect of its proving a commercial success. With this process very little retouching of the negatives is necessary, and every portraitist knows that the retouching of large heads is an important matter; for unless it be skilfully accomplished the picture, as a picture, is utterly ruined. This has undoubtedly been the case with many of the large direct portraits which have appeared in recent exhibitions. Much of this would be obviated by adopting the Denier style.

THE occultation of Jupiter by the moon, on September 3, occurred in this country at a time eminently unfavourable for observation or photographing, but in America the conditions were more suitable, and we learn that at the Smith Observatory, Geneva, New York, Mr. W. R. Brooks obtained several good negatives of the phenomena. That gentleman states that the relative apparent size of Jupiter and the moon as seen upon the sky is well shown in the negatives, and by comparison of different views the motion of the moon towards Jupiter is impressively recorded. Although the image of Jupiter is so small the belts may easily be seen in the negatives by the aid of a magnifying glass.

It has often been attempted to introduce into photographic views of evening effects, or of pseudo-moonlight pictures, a representation of that luminary herself, and, of course, it is a common expedient of the artist-painter. Yet how rarely is the result a success! The circle of white always looks artificial, and invariably seems to want some unknown alteration to produce the appearance of nature. The deficiency really consists in a want of true proportion in the representation. Few observers have the slightest idea how large the moon appears to them; in other words, what object held at arm's length and compared with the moon would appear to the eye as of the same size? If the question is asked it is very unusual to receive a correct reply, the usual comparisons varying from a dinner plate to a half-crown piece. As a matter of fact, an ordinary sized pea so held is the nearest approach to a true comparison.

A STANDARD of light is as much a necessity for the scientific photographer as to the gas manufacturer; but the latter is compelled by Act of Parliament to standardise his products, while public demand alone affects the former. This demand, however, is sufficiently strong to cause the dry-plate maker to cater for its supply, and he in consequence either calls his plates so many times quicker than the standard of wet plates, or, more scientifically, refers them to M. Warnerke's well-known standard, and gives upon the label the number of the sensitometer they develop to. Some of our readers have, doubtless, been amused by quotations in print of "35" or "40 sensitometer," still more, have been perplexed to understand the meaning intended in some cases by the sensitometer number attached, plates by different makers varying in sensitiveness as one to three (and sometimes more) being labelled by one and the same sensitometer number. The molten platinum standard is not a practical one, and, taking all points into consideration, the pentane lamp has most promise. These, and others,

are succinctly and well described in *Practical Photometry*, a work recently published at the office of the *Journal of Gas Lighting*.

QUITE lately still another method of testing the power of light has been invented, and described by M. G. Lion, who utilises the decomposition of nitrogen iodide by light. This preparation, which, when dry, is a most powerful explosive, is quite innocuous under water, and is made by digesting iodine in ammonia at a temperature of 22° C. According to this gentleman, it is decomposed exactly in proportion to the strength of the incident light, and the amount of decomposition is measured by the volume of the nitrogen gas disengaged, which is exactly proportional to it.

THE users of electric light for photographic purposes, in common with others, will have received a shock in reading how it is looked upon as certain that one of the most disastrous fires ever recorded, even in America, has been caused by the wires in connexion with the electric lighting in a warehouse. Of course, these risks are no new discovery, and the proper way to encounter them, to provide against danger of fire, has been long ago enunciated. It is to be hoped that the insurance companies will not make it a pretext for increasing their premiums to the long-suffering photographer, who is now far more heavily rated than the risk warrants. Can any of our readers explain why the risk in a photographer's premises is looked upon as so great? Although he has barbed, in the majority of cases, the dangerous ether, no relief of his rates is vouchsafed.

At a meeting of the Queckett Club about three years ago, Mr. J. D. Hardy exhibited an arrangement he had devised for photographing an object under the microscope without having to alter the position of the instrument in any way. It was, however, of metal, and too heavy for use; but at the Royal Microscopical Society's meeting last month he introduced a variation in form and material in the shape of a somewhat similar instrument made of wood, and weighing little more than an ounce, which it may be anticipated will be of real use.

WE draw attention by way of record to a long paper upon *A New Process for the Volumetric Estimation of Bromine in Presence of Chlorine and Iodine*, by Mr. Norman McCulloch, in last week's *Chemical News*. The paper, which is unsuitable for abbreviation, is interesting and useful. As, however, a small number only of our readers are likely to take a special interest in the subject, which, in some instances, would be of great value to the experimenter and investigator, we content ourselves with reference to page 259, *et seq.*, vol. lx., of that journal.

PREPARING AND MARKING SLIDES FOR THE LANTERN.
MUCH confusion formerly prevailed relative to the placing of the slides properly in the lantern. Not unfrequently they were seen upside down on the screen, or back side foremost, causing a reversal of the image. To obviate this some makers adopted one system of marking their slides, but as others adopted a reverse system, confusion became still more confounded when the unhappy demonstrator was called upon, often at a moment's notice, to exhibit a collection emanating from various sources, and marked in a heterogeneous manner.

The Photographic Club, which is composed of members of various societies in London, set themselves to reform this by adopting a general standard, and this system is now becoming generally adopted.

We are pleased to find that an influential body in the provinces—the Birmingham Photographic Society—have in their Annual Report given a “deliverance” on this subject, and it is so concise and good that we extract it in full:—

“Attention is again directed to the marking of slides. The proper method of labelling a lantern slide is to attach the name or title, so

that it may be seen on the front of the picture—preferably at the top—when viewed in its correct position. An example is given in the sketch:—

“All slides for exhibition should be three and a quarter inches square and properly mounted. They should bear the title legibly written.”

Here the whole matter is so well stated that we have only to urge upon our readers all over the world its general adoption.

COLOURED PHOTOGRAPHS.

XV.

IN our last paper we have arrived at a point which brings us face to face with the actual work of painting a picture. As I before suggested, we must look upon the presence of the photograph as we would upon a most elaborate sketch. Needless to say, in this regard the photographs will present some difficulties, such as the heaviness of many of the shadows, and the general colour of the print, the latter being not at all advantageous. This, however, may be obviated if we have everything under our control, as we may then select a method of printing which may afford little, if any, disadvantage. Suppose we had to paint a head and bust on porcelain, we can have the same printed on a carbon tissue, either in photographic tint or the more delicate and, if I may so express it, *friendly red tint*. This latter is somewhat the colour of the old red chalk drawings. If, however, we have not the option, and are obliged to work on a carbon film having the image printed in photographic tint, we can *rub down* this image to such an extent as to remove all its objectionable qualities. By *rubbing down* we can secure a perfect sketch, and of such delicacy that the tone or tint of the photograph will but little, if at all, interfere with the successful working of our colours.

When our photographic base is on, say, *albumenised* paper, matters are different, but our difficulties are not overwhelming. We have many ways of treating this kind of picture. We can use, if the picture be very dark, a little Chinese white with our first wash of colour, which will tend to remove the heaviness, and enable us in after work to secure better and more natural tones in our flesh. As I have already said, in a former paper, that the use of Chinese white should be very limited, especially in this respect, I wish it to be understood that what I have just said must not be taken to disprove the same. A photograph of the density to render its use *almost* indispensable is but seldom presented to an artist for colouring, but when such is the case I think it may be considered allowable to use it. I always prefer pure colouring if it can be successfully carried out, and in most cases *strength* of colour will be sufficient to kill the neutral and anything but life-like tone of the photograph, and in its place leave one that will truthfully represent nature. These remarks apply also to pictures printed in platinum, bromide, and such-like cool tones.

We will pursue the system of colouring as though we had made our sketch, and compare from time to time in order to thoroughly appreciate how much of this style of work is honestly applicable to colouring a photograph. We will find that nearly all the rules for painting (when the sketch as well is our own work) will apply to our colouring of a photograph, although, perhaps, not in the same order of working. To explain this point before we go any further, I will give an example. Where we make our own sketch, our first task with colour would be to secure the outline in appropriate colours, and then apply what we may term the dead colouring. Now, with a photo-

graphic base this would not be so: we should rather give our *broad wash first*, which would give a good warm tint to all the flesh, and then proceed with the colouring of the outline and other portions, as we might find most desirable.

It may not be amiss to divide the process of colouring, whether it be on a sketch or a photograph, into three distinct parts. The first of these we may restrict to the outline and the placing of the local washes representing the *masses* of colour. The second consists of what we may term the painting or working out of all the delicate details of the portrait. And the third may be set down as the finishing of our work in every detail, both as regards general effect as well as style of manipulation.

It is rather difficult to carry on this comparison, so I hope my readers will kindly be more disposed to follow the spirit of what I set down than try to find out a weak point in it. We will, supposing we understand each other up to now, proceed with the colouring of a head of a fair subject.

In the case of a sketch, we would find in all probability that our outline was rather strong; we would, therefore, reduce it by rubbing a little bread or indiarubber over it, so as to leave a very faint indication, but not to obliterate it. In this condition the colour of the pencil will not interfere with the purity of the colours when applied. In a carbon on porcelain the treatment would be somewhat the same. We are almost certain to find the *print* too strong, a fact which would, if not altered, injure the purity of our colouring. We would, therefore, proceed to rub it down with eraser, working it slowly and carefully, until we had but a faint indication wherever great delicacy of colour was necessary.

In the sketch, we would now make a firm outline with the brush, of course laying the proper colours on each part as we proceeded. We should also try to do this in such a way as to represent the full strength at once; we should also be very careful to represent faithfully the various forms, and, if possible, improve the drawing. As an example of this, should the eye be a blue one, put the iris in with cobalt; this we can lower in tone for a grey eye with sepia, or Vandyck brown for a dark eye. The pupil we can paint with sepia, should it not be too dark. The eyelashes we can paint also with sepia, and indicate the eyebrows as well. If the nose be in more or less shadow, it will be found advantageous to mark it out with brown madder. The ear may be outlined with the same beautiful and useful colour. The same colour may be used for the nostrils, but it will be found of considerable advantage to mix a little pink madder with it. This latter combination may also be used for the deep shadows of the mouth.

The leading and most characteristic shadows and other markings of the face should now be put in, and this, too, as near their full strength as is possible. A general shadow colour which is well suited for this purpose may be made by a combination of Indian red and cobalt, care being taken not to allow the latter to predominate and so produce a slaty tint. I do not think there is any better, more useful, or cleaner colour for painting in the shadows on flesh than that resulting from the judicious combination of Indian red and cobalt. The most important shadows to require treatment are those which indicate the sockets of the eyes, the lower parts of the nose, and also that below it, under the chin, and below or behind the ear. In working these shadows we should use considerable judgment, as beautiful effects may be gained by a skilful combination of washing and hatching. If there be a bluish shadow under the lower lip, put it in with cobalt.

The lips come next for treatment. These we paint with a mixture or tint composed of vermilion and pink madder. As a rule, it will be found best to stipple on this colour; we can secure the lights on the lips by either leaving them in the first instance or taking them out afterwards with a wet brush. This done, we give a general wash of Venetian red or light red all over the face, excepting only the eyes. Now, while this is drying we can outline and wash in, with sepia, the most prominent markings in the hair, securing any peculiarities that may happen to be there. It will be advisable to begin with the darkest and most decided forms, and so proceed until we have put in the entire of the hair in touches as nearly of proper strength as possible. If there be white linen next the skin it will be well to now outline it with a delicate tint made by mixing cobalt and sepia. All the rest of the objects in the picture should now be outlined in their respective colours, and then washed in. To do this, the best way is, as before, to start with the decided tones and leading touches which indicate the form of the object, and then give a general wash over all.

Having gone thus far, we have secured, I will presume, an accurate and coloured outline in which all the leading shadows and principal details are fully defined. It is a very uphill struggle to complete a successful picture by means of shadows and colours, if we have to a serious extent failed in correctly carrying out these preliminary points.

On the contrary, if we are successful in the execution of this portion of our work, we can rest assured we have secured the resemblance as well as the general effect at the very beginning of our picture.

Before going further, we will see how far all this can be successfully applied to a photograph. Really there is but little to do except to somewhat alter the rotation of our work. On the sketch, we painted in our leading shadows and details and then placed a general *wash*, while on the photograph we must do exactly the reverse. On the photograph, our masses of colour must be washed in first, our leading shadows after. There are many reasons for this being necessary. On the majority of papers used for photographic pictures, the colour rests too much on the surface, and is too likely to *lick up*, to admit of the same treatment as a water-colour on the ordinary Whatman or other papers, which absorb and hold the colour firmly. Of course, there are some papers where this is not the case, and in such we are at liberty to do as we may each think best. On a platinum base either may be worked, so also on bromide or salted paper, but on carbon or albumenised paper it would be next to an impossibility. I feel sure this will be self-evident to all beginners on the very first trial.

By the time we have carefully finished outlining and massing the shadows on the hair, dress, and other objects, the wash of Venetian red will have dried upon the face and be ready for further work. It will be found advisable now it is dry to hatch over the entire face with the same colour. Let your colour be *thin* and flowing, taking care at the same time that it is not too wet. It is best to begin this hatching upon the forehead, and directing your strokes in such a manner as to indicate the roundness which this part of the face has in nature. Much of the breadth and vigour of the head, as well as its roundness and beauty, depend upon our accomplishing this treatment successfully.

This process of hatching having been *once* completed, we must do it again, only this time we must *cross* the hatching by slightly altering the direction of our strokes. It is not necessary that the lines should cross each other much, but, above all, care must be taken to avoid crossing them at *right angles*. To cross at right angles would be simply fatal, as nothing soft or graceful could ever result from such a treatment. This method of laying on colour should be practised until a certain facility is gained, as it may be laid down as a rule that in painting flesh all the colours used must be *hatched* and not *washed*, save and except in the first instance, when we give a *wash* of venetian red. In the case of men's portraits it will be found necessary, at times, to hatch a rather light tint of Indian red over the lower portion of the face in addition to the Venetian red.

Let us see now where we are, both as regards the portrait whereof we have made the sketch and also the photograph. It is laid down that we must secure all our outlines and leading shadows in the various colours of nature, or those that represent that effect as nearly as possible, then lay a wash of Venetian red over the face and leave to dry. When dry, we cross hatch with Venetian red until a certain degree of power, roundness, and warmth is secured, which may be said to be the successful termination of our first painting. I think if this be closely considered, all these points can be carried out successfully in painting a photograph. The fact of our being almost obliged to give the *wash* first, instead of later on, will not to any material extent alter the beauty or truthfulness of our portrait, or render the treatment of our picture less artistic. Indeed, the order to be observed in painting a portrait on a photographic base, say carbon tissue on porcelain, can be equally carried out with success upon Whatman's paper. I think it may be fairly set down as a matter of *expediency* which we adopt, and not be considered as in any way interfering with the value of the portrait from the point of its artistic merit.

As I say, our *photographic outline* (for as such we can truly look upon it) can be so thoroughly brought to suit the requirements of an artist about to make a painting, that we can treat it according to all the best rules laid down by the most eminent authorities for the production of a so-called legitimate painting. REDMOND BARRETT.

COMPARISON OF EIKONOGEN AND PYROGALLOL DEVELOPERS.

[Abstract of an article read before the Chemical Society of Washington, U.S.A.]

THE ordinary photographic developer is composed essentially of a reducing agent—pyrogallol, hydroquinone, &c.—and an alkali. A new developing agent has recently been introduced, under the name of eikonogen. This is the sodium salt of amido-B-naphthol=B-sulphonic acid, $C_{10}H_5\begin{Bmatrix} HSO_3 \\ NH_2 \\ H \end{Bmatrix}$

The comparison of developing agents should be made with reference:

to the quantity of alkali required to develop a properly exposed plate. Pyrogallol being the agent most generally in use, it was chosen for comparison with eikonogen. Experiments showed that about three times the weight of pyrogallol was a good proportion of eikonogen; hence the following formulae were made out, which, on trial, proved satisfactory:—

PYROGALLOL SOLUTION.—P.

Pyrogallol	2 grammes.
Sat. sol. sodium sulphite	50 c.c.
Water to make	300 c.c.

EIKONOGEN SOLUTION.—E.

Eikonogen	6 grammes.
Sat. sol. sodium sulphite	50 c.c.
Water to make	300 c.c.

ALKALI SOLUTION.—A.

Potassium carbonate, dry	20 grammes.
Water	200 c.c.

For development, mix three parts of P or E with one part of A. This gives developers containing in each 100 c.c.

Pyrogallol	0.5 gramme.
Eikonogen	1.5 "
Alkali	2.5 grammes.

The comparisons were made by exposing plates in the camera, cutting them vertically across, and developing the halves in the different developers. Development was carried on for the same length of time for the halves of each plate, and they were passed through alum bath and hyposulphite together. The negatives and prints were shown.

The results are summed up as follows:—

1. Eikonogen, used in the proportion of 1.5 gramme to 100 c.c. of mixed developer yields denser negatives than pyrogallol used in the proportion of 0.5 gramme to 100 c.c., the quantity of alkali being the same in both developers.
2. When the proportion of eikonogen is reduced to one-half the quantity given above, using the same amount of alkali, the density of the negative is not quite equal to the density given by 0.5 gramme of pyrogallol.
3. There is no difficulty about getting any desired degree of density with eikonogen; the plates do not become stained.
4. Eikonogen negatives print much quicker than pyrogallol negatives of apparently the same density.

ROMY HITCHCOCK.

THE IMPROVEMENT OF FAULTY NEGATIVES.

No. II.

In a previous article I referred to such faults in negatives as those showing opaque and transparent appearances, and instanced a case of the former kind. I now proceed to describe a method of working which I have found most serviceable in the way of removing those faults that are opaque in the negative.

Whenever it happens that a flaw assumes such a shape as to be next to impossible to deal with or overcome in the negative, perhaps there is no better way of proceeding than by making a transparency of the same size, but little consideration will be required to understand that, when this is done, such opaque faults will assume a transparent appearance in the positive, and, as I stated previously, it is nearly at all times a matter of much simplicity to deal with a fault when it assumes a transparent shape. It then comes within the scope of most amateurs to deal with in the usual way of spotting or retouching out with a lead pencil, or, in stubborn cases, the aid of a fine sable brush and a little colour will generally be found useful. In the course of my practice I find it is not this working up of the transparency that gives my pupils so much thought, although doubtless there are numerous gentlemen who at first consider modelling a negative quite beyond them. Still, when they get a little insight into the practice of retouching, they soon find out it is quite within their power to do a considerable amount in this way. I find it is the pulling off and getting a good transparency of the same size that gives them most trouble. Here, doubtless, the rule with most amateurs is to put a dry bromide plate into contact with the negative in an ordinary printing frame, and, by a quick exposure to daylight, or a somewhat longer to artificial light, make the transparency. And here is just where they begin to go wrong in this class of work. I am no believer in the making of a transparency by contact. It is so simple, some say, and so much easier than by the roundabout method of exposing through the camera, that doubtless many are found who never

try the more scientific way of going about the operation. Still, I think but little consideration will be required at the hands of my readers to see that, when doing this work by contact, and using a fast bromide dry plate, an operator is almost powerless to cope with many of the imperfections, such as thinness in some parts of a negative, or over-density in others, both of which are quite easily dealt with in the case of slow printing by shielding, or printing up, dodging, &c., but which, when working with a fast bromide plate in contact, gets completely beyond his power to satisfactorily cope with. Were there no other objections to contact work, this alone, in my estimation, is quite sufficient to show that, in but few cases, can any one expect to turn out such good results by contact as by the more scientific way of working through a camera. I am quite aware that it is not every worker who is provided with a copying box to enable him to go about the work as I suggest, but the rigging up of copying box is such an easy thing to do that no one need really advance such an objection. In the making of a copying box there need be no launching out into an expensive article. I find some of my friends get along first rate with the rough-and-ready, home-made article, which is nothing more or less than a suitable box with an aperture cut in the bottom, against which the negative is supported with the aid of a few tacks. Armed with such, an amateur can go ahead and produce from faulty negatives transparencies of much evenness and pluck, for there need be no difficulty, after a single trial, in hitting off the correct time. In the work we are considering very much depends in being able to pull off from a faulty negative a really good transparency. By this I mean a positive showing the finest details, and one that on development gives full range of tone from high lights to detail in shadows. And, to do this, I know for certain there is no better way of going about the work than by the aid of a copying box and camera.

Where is the worker who can at all times depend on having all his negatives right in the way of equality in thickness of the films? When printing such through a copying box it is a matter of much ease to so shield off the thin parts with the aid of a little bit of paper by wafting it in front of the negative in such a manner as to equalise the amount of light that is passing through. There is no difficulty in doing this when a camera is brought into requisition and a small stop used, even should the worker be exposing a runaway dry plate, for by stopping down, and, if necessary, interposing a sheet of ground glass or tissue paper between the light and negative, matters can be easily arranged so as to permit of exposures ranging well on to a minute through the camera, if, in fact, in many cases even much longer time will not be required, so that an operator has his hands quite free to shield or dodge up his exposures. Not so, however, when attempting this work by contact. So much, therefore, in the matter of the best way of making a transparency. Now just a few words as to what, in my opinion, is the most desirable plate to use. In my practice I invariably use collodion, but I am quite aware not one in fifty amateurs or professionals either, for that matter, could now be found who know how to work a wet plate—more's the pity. If a bromide dry plate is the most convenient, or, in fact, the only opportunity an operator has of doing the work, by all means let him get as slow a plate as he can, and by a tentative system of development let him do all in his power to produce an A 1 transparency. When he has obtained this he is master of the situation, and any faults in the original negative now apparent in the positive must now be dealt with. In my previous article I referred to a case of opacity that had to be removed. A very little consideration will now suffice to show my readers that in the case referred to the removal of the fault becomes so easy in the transparency as to be quite within the scope of any one; in fact, all that is required being a few judicious touches of an ordinary lead pencil. This done, the positive is again placed in the box, and another sensitive plate inserted in the slide. This time a negative is pulled off, and on this any little retouching or modelling that may be required is done, the result being a negative free from the original flaw or eyecore, and very likely in some other respects much superior also. It is quite wonderful what an amount of improvement can be effected on a negative by working on the lines I have laid down.

I have instanced a case of faulty posing, but it is not in this alone in portraiture that we meet with cases of opacity which become an eyecore, or at least faulty in the finished print.

In the matter of lighting we frequently find errors are committed which can also be overcome quite conveniently by the method I have stated. I quite recently met with a case of a gentleman whose tender point was his grey hairs. Like every one else, he felt years did bring a few, but in the picture sent him, owing to faulty lighting, his hair came out on one side snowy white, and this was more than he could stand, so he returned the proof, saying he knew he had a few grey hairs, but was not quite so far gone in that direction as the photograph showed; in other respects the picture gave satisfaction.

I can remember well pulling off a transparency, dodging it up, printing a new negative, and sending a picture entirely free of grey hairs, and, need I add, it was prized very much. Such are a couple of cases that have come within my own experience lately in portraiture where flaws of opacity have been entirely overcome.

At present I am dealing with a somewhat similar trouble in the shape of a case of halation. Here a splendid negative of an interior is much marred by a glaring case of this annoying trouble. From time to time one hears of this and that preventative in the shape of backing the plates previous to inserting them in the slide, &c. I do not know whether or not I am singular to others in my experience, but I have always found the best way to prevent halation is to deal with the offending light that comes through the window. I am no believer in the backing of a plate as being a sure preventative. In my opinion the only way to get entirely rid of this nuisance, in the case of interiors, is by so blocking out the light as not to cause the offence. But in cases where any one has to make the best of what they have placed before them, I know much may be done to mend matters, if not, indeed, entirely remove the results of halation, by carefully working up the positive previous to pulling off the final negative. In attempting this, however, it is not at all times an easy matter to fill up broad spaces of halation with the aid of a pencil or stump. I often, in such instances, get along first-rate by flooding the glass side of the positive with ground-glass varnish and working in same with the aid of a sable brush and a modicum of Chinese white, working in with pencil, &c., as much as can be done on the film in the way of detail. This sort of work takes a little patience and neat-handedness, but the worker gets his reward when he looks with pride on the success which finally attends his efforts. In my next I hope to refer to a few other cases.

T. N. ARMSTRONG.

AMATEUR LANDSCAPE WORK IN PLANE PERSPECTIVE.

THERE is strange perversity in human nature, or, at least, in some types of it, and the amateur photographer occasionally exhibits forcible examples thereof. That the eyes can see only the amount of their trained capacity is an oft-repeated truism, but it has rarely been so well exemplified as in a recent case, which may point a moral, if it does not adorn a tale.

A landed gentleman having an estate in the North of Scotland, bitten by the photographic craze, began it, and with the pertinacity of a Scotsman, determined to become as good a photographer as he had already made himself a banker, a farmer, arboriculturist, &c. So far as the most lavish outlay, the best text-books, and assiduous practice could do to help a person naturally clever, he succeeded in being able to make very presentable negatives of the wild mountain scenery around his highland home. During the currency of his last year's residence there, among many others he had secured one which he considered his best photographic attempt, and which embraced several cherished bits of scenery he had never seen previously depicted. The subject was a wild highland valley, or rather mountainous gorge, through which a peaty burn came rushing and tumbling: here over a pebbly bed, there over a miniature fall, and anon dashing itself into spray against the huge rocks bounding it on either hand, till coming nearer the foreground they narrowed almost to a crevice, through which it rushed; and comparative smoothness was secured by a strongly built curved embankment forming a roadway, which was partly cut out of the slope of the mountain side and partly sustained by this built up from the bed of the torrent, by which comparatively easy access could be got to a favourite, deep, still pool—the delight of his heart—and from which he had inveigled many “a lusty trout.” The scene was closed in the distance with the high-towered mansion perched above the densely wooded slope, on which it had been built with a fine eye for the picturesque outlook from the smoking room which formed the upper storey of the tower, one side looking down the burn, which in spate was a rearing torrent, and the others commanding views of the more or less varied mountain scenery around it. Altogether it was a charming spot, and the picture, as a negative, beautifully executed but for one slight defect. In order to get in the house and surroundings with a peep of sky, while keeping in the favourite pool in the foreground, the lens had been strained to its utmost, and the camera had been slightly tilted, and, what was not so much noticed, in the small upright *carte* print it had also been deficient in the true horizontality. This, however, he did not see, or his eye had been accustomed to the defect.

Our amateur friend, pressed by his family, determined to have an oil picture painted from one of the remaining copies, the negative having come under the usual fate of favourites—got broken or destroyed; and he gave the commission to an artist, of whom he had had

several landscape pictures, with strict injunctions to keep to the photograph. It was in vain that the latter stated that he had never been in that part of the country in any of his sketching trips, and so could not do justice to the subject with its local colour and other such items, but, as stated, with no effect. Was there not the card, the verisimilitude of the place, and from a point on which no artist would dare to perch himself by choice? and did it not show every stone, and pool, and shrub, and tree, and the mansion itself? and then it was the only photograph which had ever been taken from that point, and being a photograph, and a good one, it must be all right. The additional remarks that he liked the artist's work so well that he had selected him in preference to others who were mentioned, together with the injunction to put his best efforts on the picture and charge his own price, were quite temptations enough, and the commission was accepted.

In order to be as exact as possible, the artist, Mr. W—, a well-known man, determined to get it enlarged photographically to about three feet in height, thus necessitating a new negative and transparency, which allowed of careful drawing in of the landscape portion of the work, as the tilting and unevenness of the original did not much matter, for the rocks or river on which that sort of error occurs does not tell so severely. A slight tilt more or less to the already contorted strata, or an inclination of a degree or two to the trend of the trees, did not much affect the general truthfulness of the picture; but the enlargement showed the defects mentioned on the building, and after some consideration he decided to have that portion of the subject photographed and printed on the canvas, which was done from a 14×12 negative.

In order that the lines should be kept true and square, and for reference in finishing, true square lines were drawn crossing each other before printing the house in its place. During the progress of the work the client called several times, but could not, or would not, see the defects in the drawing of the building, and ultimately insisted on it being finished as he had photographed it, thus proving the assertions at the commencement of this article, which amount to the old proverb, “That there are none so blind as those who won't see.”

The artist, like Mr. W—, who is no photographer, thought he could improve the foreground, and did so with considerable addition to the picturesque effect, in my own judgment and that of others quite as fitted to criticise and accustomed to judge; but this also had to be erased, and the original faulty photograph followed as closely as if it had been absolutely correct.

The slightest knowledge of the principles of plane perspective would have insensibly trained the eye and formed the judgment of our amateur picturist and saved the perpetuation of what is really wrong in depiction, no matter whether executed by the camera or drawn and painted by the artist.

W. H. DAVIES.

A NEW PLATINUM TONING PROCESS.*

I WILL assume, therefore, that paper has either been bought or sensitised at home, and the proof is in the printing frame. It is, of course, evident that the progress of the print can be watched in the usual manner, but the extent to which printing is to be carried on to compensate for loss in the subsequent substitution process demands a few words.

There is but slight loss from this cause in this process. Some diminution of tone is, of course, observable, but in giving working directions, I should say that the loss is about the same as that in gold toning, and I print therefore till the high lights just show signs of degradation. However, in the demonstration with which I will conclude this paper, you will be able to see for yourselves the actual loss of detail. It must also be remembered that plain paper prints always lose in intensity proportionally more than albumenised prints. This loss takes place in the preliminary washing to remove the free nitrate. It therefore follows that these papers should be printed somewhat deeper than albumenised ones.

On removal from the printing frame the print should be well washed in several changes of water till all the milkiness disappears. The presence of these free silver salts do not in any way injure the subsequent toning processes, but they render the toning solution, which is used in a somewhat concentrated state, somewhat dirty and cloudy. I therefore prefer to wash thoroughly.

The toning solution is made up as follows:—

Stock solution A, chloroplatinite of potassium 60 grains.
Distilled water 2 fluid ounces.

This is the ordinary solution as given by the Platinotype Company:—

Take of A 1 drachm.
Water up to 2 fluid ounces.
Nitric acid 2 or 3 drops.

* Concluded from page 782.

I prefer to add HNO_3 to the solution to ensure its being in an acid condition, the least trace of alkalinity being sufficient to considerably retard the action, but with many papers it is unnecessary.

For those workers who do not use the platinotype formula, I would point out that the above solution means two grains to the ounce of water, and, therefore, the sixty-grain tube can be at once made up to thirty ounces and duly acidified.

If the weather is cold, I prefer to warm the solution, say, up to 80° Fahr.; this has always an accelerating effect, but too much heat should not be applied to a strong solution, as it will eat away the half tones.

The prints can either be immersed in this solution, or if only a few are to be done, can be floated on a small quantity of the solution poured over a levelled plate-glass dish. With the above strength, the toning process takes place very rapidly, in from two to five minutes, according to the tone it is wished to obtain. If stopped at an early stage, the prints have a brownish colour, whilst if carried on till all redness, as viewed by transmitted light, disappears, they become of the well-known platinum black. If several prints are to be toned at once, it is perhaps best to still further dilute toning solution, or its action will not be under proper control. In fact, in all cases where it is wished to obtain warm tones, and to have the action well under control, I should advise a considerable weakening of the developer, and to make it up as follows:—

Stock solution A.....	1 drachm.
Water up to	8 fluid ounces.
Nitric acid	2 or 3 drops.

Several prints can then be immersed in the above bath, and turned over and watched as the toning proceeds.

After removal from the toning bath, the prints should be placed in a basin of water rendered alkaline by carbonate of soda or ammonia; this is to neutralise the free acid of the toning bath, which, if carried over into the hyposulphite, would cause a precipitate of sulphur, and a probable yellowing of the high lights of the print. Where only a few prints are being manipulated, the hyposulphite bath itself can of course be rendered alkaline. In the fixing bath, if the toning has been complete, the prints should not change colour and lose nothing in intensity; but if the toning has been stopped at the reddish purple stage, they will change to a brownish black, this colour depending, however, somewhat on the process by which the print has been prepared. This change of colour is due to the silver salts that are left in the paper being altered in colour by the action of the hyposulphite of soda. When, therefore, it is desired to match any given tone, it is advisable to treat the prints before toning with a weak solution of salt in water. The action of this is to dissolve out all the purple subchloride, and leave only the red or brown suborganate of silver. As I have mentioned, in the early part of my paper, this has no action on the toning action, if we except a very slight general reduction of intensity.

The several prints handed round to you have been prepared with the idea of showing some few of the different tones that can be obtained by different salting and sensitising mixtures in connexion with different materials. They are on silk, nainsook, satin jean, Whatman's rough surface drawing papers, Creswick paper of 1865, having a slightly yellow tinge; also a thin bank post paper, that appears to promise excellent results, and is almost thin enough to permit of its being mounted in printed books without bulging them too much. Many samples on ordinary commercial barium salted paper are also shown, and some on Watson's matt-surface sensitised paper. Generally speaking, I may remark that the English animal-sized papers tone with more difficulty than the starch or resin-sized German or French papers. This is probably due to the fact that the decomposed sizing is in an alkaline condition, in which case a preliminary bath of citric or acetic acid would appear to be advisable.

Before I proceed to my demonstration, I presume I must say a few words as to the permanency of this process. I had hoped to find that the substitution of the platinum was complete, but I am obliged to confess that this is not so. It is possible to replace the silver to a very large extent, but not completely. This is equivalent to saying that the process is not as permanent as the ordinary platinotypes of Willis.

I have here silver prints toned by gold by my own process, and a print by the cold-bath process of Willis. These proofs were torn into strips and subjected to (1) chlorine gas, formed by the addition of hydrochloric acid to bleaching powder (hypochlorite of lime); (2) chromic acid; (3) sulphuretted hydrogen (formed by the addition of sulphuric acid to a soluble sulphide); (4) bichloride of mercury; (5) alum $\text{AlK}(\text{SO}_4)_2$, slightly acidulated with sulphuric acid (to represent the condition of a sour paste containing alum). I must here bear witness to the remarkable stability of the cold-bath platinum prints, which passed through the above ordeals absolutely unchanged. The gold-toned prints (gold chloride and car-

bonate of soda) were unaffected, or only slightly affected by the mercury, showing that the toning was pretty complete; but the chlorine had entirely eaten off every trace of the image, leaving only white paper. The sulphuration first somewhat darkened, but then yellowed, the colour of the deposit. The alum also had a very decided lowering of the tone. In the prints prepared by my own process, the mercury had not the slightest effect; the moist chlorine had, however, considerably damaged the image, but still there was a very considerable amount left; the sulphuration and the other tests had very much the same result as on the gold prints, but in a less degree. Some similar prints on plain fixed chloride, and developed bromide of silver papers, were, with the exception of the sulphuration and alum tests, of course absolutely destroyed.

From the above results I deduct, therefore, that prints prepared by my process, although vastly inferior to the ordinary platinotype prints, are yet a good deal more stable than those prepared in a similar manner, but toned with gold and vastly superior to developed bromide papers. Looking at the well-known longevity of such prints, when carefully prepared, this may be assumed to promise them a fairly long life.

LYONEL CLARK.

[Mr. Clark then proceeded to tone some prints that had been previously printed on some of Watson's matt-surface sensitised paper. The toning dish consisted of an ordinary glass-bottomed dish, provided with three levelling screws. This dish was first levelled by means of an ordinary level, and four ounces of toning solution were poured on it. With this some twenty 12×10 and 10×8 prints were rapidly and successfully toned.]

AMATEURS AND TONING.

OF all the various operations connected with the production of pictures by photography, perhaps there is no other that presents more difficulties to the amateur than that known as "toning," and yet an amateur who devotes any appreciable amount of time and care to the art he loves should, as a matter of fact, be able to tone as well as the professional, or, we will say, the average professional. That the general run of amateurs find the operation a veritable stumbling-block in their path is clearly proved by the number of letters weekly received by the editor of this paper, and which he states usually enclose examples "showing an entire misconception on the subject of toning generally." The failures he attributes mainly to over-toning, and to the manipulations, the paper employed, and lastly, but not least, to the negatives themselves.

On the subject of taking the negative, it is not my intention to write in the present paper, as I believe a fairly good tone can be obtained whenever a fairly good print is given to operate upon. With regard to the paper I would decidedly say a few words, and herein I consider lies the cause of the majority of amateurs' failures to obtain a good or pleasing tone. Most amateurs, in fact fully ninety per cent., use commercial ready-sensitised paper for their prints, and though there are a few brands of this that both print and tone well, there are also many with which it is next door to an impossibility to obtain anything like a decent tone. I speak from experience, having had many prints produced by amateurs sent to me to tone and finish. The presence of acid in the paper, while tending to improve its keeping qualities, has just the reverse effect when the operation of toning is considered. The amateur who does his or her own toning had better by far go direct to the photographer for sensitised paper which, if it will not keep colour so long as the dealers' ready-sensitised, will at any rate tone much more easily, and at the same time yield much better results.

Another prolific cause of failure is the use of too new or too strong a toning bath. An amateur who has a few prints to tone, as a rule pours a little water into a dish, adds thereto a little gold and a little acetate of soda, and forthwith commences the operation of toning, with the result that his prints go mealy, and tone at the edges before the centre is touched. I once pointed this out to an amateur as the cause of his failure, and was astonished to hear that in his opinion so long as the gold had been in solution for twenty-four hours he might mix the bath and use it at once. In case others might share this opinion I would specially impress upon them that even though the chloride of gold has been in solution for twelve months, the acetate of soda toning bath must be made up at least twenty-four hours before use if it is desired that good tones are to be obtained, and, what is more, it will act far better if it has been made up twenty-four days instead of twenty-four hours.

Too strong a bath has an equally bad result as one that is too new; true, it tones more quickly, but here the old dictum of "more haste, less speed," well applies. Even if the prints be good, the paper and the bath all that can be desired, it is still possible to fail in obtaining

a good tone, and many such a failure is attributable to the insufficient washing of the print before immersing it in the toning solution.

The prints to be toned should be washed thoroughly in at least three changes of water, in fact, until no milky appearance is given to the latter: failing this the tone is sure to be degraded, and the whole print will have a muddy appearance—the dirty brown or murky grey which many amateurs recognise only too well.

As it is justly observed in the sub-leader on page 679, "The particular toning bath employed has very little influence on the colour of the print." The toning agent in all is chloride of gold, and whether it be combined in solution with acetate of soda, carbonate of soda, borax, or what not, almost identical tones can be obtained with each and every bath. However, the general requirement of the great body of amateur photographers seems to be for a good and reliable formula, and one that is easy to make and easy to use; hence I am induced to give for their benefit the following formula, which I have used for years, and which, if good prints are given printed on good paper, I have never known to fail in giving satisfactory results:—Into a gallon stone jar break a fifteen-grain tube of chloride of gold, and add half an ounce of acetate of soda, and a small pinch of chloride of sodium (common salt), pour on this about a pint of boiling water and let it stand for an hour or so, then fill up the jar with rain or distilled water, and let it stand for at least twenty-four hours before using. When the bath is required for toning, pour into the dish just the quantity required for present use, and when the toning is completed throw the used solution away. That in the jar will keep good for years, and as no used-up or partially used-up solution is poured back, it can be used to the last drop without requiring the addition of fresh gold, added to which it cannot become contaminated by anything which might find its way into the toning dish, or that portion which has been used therein.

The best way of judging the colour of the print is by holding it up to the light and looking through it, as some papers acquire a surface-tone very quickly, which disappears in the fixing.

C. BRANGWIN BARNES.

EXPERIENCES OF AN AMATEUR PHOTOGRAPHER.

I SHOULD lead you through a tangled maze were you to follow me into even a casual reference to the innumerable experiments which have been made to simplify and popularise the processes by which a photograph is brought to its conclusion. The literature of the subject is at once exhaustive and exhausting.

Within a few years the wet plates have largely given place to the dry, and it has been delusively suggested, possibly by a far-sighted commercial enterprise, that any one can take a creditable picture. As a consequence, a host of amateurs have arisen, who have ignorantly worshipped the sun, and coaxed him to do a great deal of work of which he is probably ashamed. This host infest the highways and byways of creation, making nature almost sorry that she ever condescended to show her face, and sick at heart that she can possibly look as she is sometimes represented. For myself, I confess to having had in the past a desire to look into the scientific elements of the problem more thoroughly than is common, but my ardour was somewhat dampened when I found, after meditating on this simple theorem for a couple of hours,

that it did not present itself to my mind with that lucidity which I am apt to enjoy on some other subjects. I safely concluded that the gentleman who made the equation was entirely correct, and that it would be verging on impertinence to even corroborate his statement by any little demonstration of my own. The originator of this puzzle is Lecturer on Photographic Chemistry at the Imperial Technical Academy of Vienna, and is accustomed to deal in axiomatic truths, of which this must be one, as every thoughtful mind will instantly discover. I have no desire to doubt his statement, not the least in the world, for I have great respect for mystery. Acquiescing, therefore, in the most cordial manner in the profound and beautiful truth contained in the above hieroglyphics, and inspired thereby to exercise my own creative faculty, I have produced a proposition which, it seems to me, is equally self-evident, viz., $\text{A M A T E U R} + \text{O U T F I T} = \20 . This equation interested me exceedingly, and I proceeded at once to investigate the intricacies of the chemical combinations of the white of an egg and washing soda.

My personal experiences must needs be sung in the minor key. Had I not been possessed of qualities which somewhat resemble obstinacy of purpose I would have sunk into a photographic grave long since.

Fired with zeal to put all the beautiful nooks and corners of the world into one vast picture-book, I hid me to a large dealer in cameras. Perhaps it is unnecessary to say that I was received with flattering consideration, for I took my wallet out at the beginning of the interview, and was immediately assured that modern invention had at last reduced photography to a mere matter of routine. All one needed to do, so I was

assured, was to follow the instructions laid down in the manuals, and he would soon find himself the astonished and happy possessor of numberless mementoes of a summer vacation. Mistakes were sometimes made, but they were the result of an unpardonable carelessness, and in my case that was not supposable. I had absolutely nothing to do except to expose the plate properly, develop it with judicious care, print from it, tone and fix the prints skilfully, and then I should be master of the art. All this fell on my unaccustomed ear with a sweetly solemn sound, and I forgot for the nonce that I had yet to learn the meaning of the words—developing, toning, fixing, and printing. With a dim feeling that the impatient world had waited long enough for me to show it what a real genius could do, I purchased everything necessary to a complete outfit, and quite a number of articles which I have up to this moment found no earthly use for, and probably shall not while my eyes are strong enough to focus a landscape. The liberality of my commercial friend in advising me concerning what I ought to have was simply astounding. At the end of a very delightful interview my wallet had a lean and hungry look, and I was still indebted to my "guide, photographer, and friend" to a considerable amount. I had purchased a fine camera and lens, a dozen dry plates, a cartload of chemicals, and innumerable *et cetera*, and I retired with the boundless hope of a resplendent future. The wheels of my chariot had not yet touched the corduroy road which lay between me and the achievement of my purpose, and which was destined to jolt every bone of my body out of place, and reduce me morally to the consistency of a jelly-fish.

My home for the summer was on the shore of Casco Bay, in Maine. With twenty or thirty rocky and sandy islands in view, it was easy to find lovely spots which seemed anxious to be transferred to glass. I restrained my impetuosity, however, until I had gleaned from my manuals some indistinct idea of the conditions to be observed before a picture could be obtained. I knew that after the sun had done his part of the work, the oxalate of potash and the protosulphite of iron and the hyposulphite of soda were to be skilfully harnessed, not abreast by any means, a mistake to which beginners are too prone, but tandem, that they might drag the unwilling image from its hiding-place in the nitrate of silver on the dry plate; but such malignant circumstanced got control of me that I actually tried twenty-two times before I succeeded in producing any picture at all. Whether I was unusually stupid—an intimation to which I am not over-hospitable—or whether the cunning powers of the air took especial pains to balk me, I cannot say. Time and again, so frequently that the harrowing remembrance of those unhappy days almost makes each individual hair stand on end, I put the plate into chemical number one, carefully prepared according to the formula which my friend the merchant assured me admitted of no possible mistake, and watched with anxious delight the outlines of beauty as they leaped with astonishing rapidity into view; and just an equal number of times my heart sank, and I expressed an opinion remarkable for its candour, though it need not be repeated here, when a dull grey cloud gradually overspread the plate like a thick sheet of lead, and my picture disappeared into the regions of the unknown. I tried to resuscitate it by pouring a portion of every chemical I had upon its face, but in no instance was I able to call it back. I sighed, I even spoke of myself with opprobrious epithets, but it availed not. On other occasions the developer did its work more deliberately, and I was charmed with the bit of landscape that became visible, but when I put the plate into the soda a change occurred, and it grew blacker and blacker, until at last, when I removed it and held it up to the light, I had a 5×8 pane of clear window glass, with not a vestige of anything on it. The length of exposure was, of course, my first stumbling-block, as it is to all amateurs. I sought information very diligently on this subject, but somehow photographers always evaded it; and though I discussed the matter with a very eminent artist for a full half hour, I came away with a dull feeling of dense ignorance in my heart. I was told that everything depends on the time of day, the state of the atmosphere, the cloudiness of the sky, and many other things which I have forgotten; and when I insisted that he ought to be able to tell me within sixty minutes of the right time, he grimly smiled, and answered that in one instance his camera was in position in gloomy Trinity Church for twenty-four hours before the light made its impression; and that in another instance a perfect picture was taken by the flash from two Leyden jars, or in about the twenty-four-thousandth part of a second.

With these two extremes in mind, I focussed my lens on a dwelling-house, removed the cap, and waited fifteen minutes. It was a bright, cloudless day, and the sun was shining in a blaze of glory at my back. The picture which was the result of the experiment was not in every respect a success, as my fellow-artists can easily guess, for when it came out of the developing bath it looked like a thin coating of disgusted clay, with here and there a splash of black, but with the house so far in the remote background that it was quite invisible. My perplexity was increased by this experience. Being far removed from any professional friend, I could not decide whether the exposure had been too long or too short. I reasoned from the slender premises at my command that the sun ought not to be tinted as to time, and if I was generous with him, he would, in turn, be generous with me, and do the work thoroughly well. The grossly ignorant may not be aware of the fact that the sun had finished his task at the end of about three seconds, and he spent

the remaining fourteen minutes and fifty-seven seconds in spoiling the picture out of revenge for my stupidity.

I try to get one afternoon a week for a photographic tramp, and it refreshes me for all the other days of sedentary toil. Within half an hour of my residence there are little nooks and corners waiting to be copied on sensitised paper. I pack up my valuables, rush for the cars, and enter at once on a new life.

Let me describe one of my trips, and perhaps some forlorn and shipwrecked or health-wrecked brother will go and do likewise. It was a beautiful day in December, and the air had a crispness in it which made one's blood tingle. I was in the midst of some frightfully tangled work. I had tugged at it with desperate earnestness, or rather earnest desperation, but it was obstinate, and would not allow a single ray of daylight to penetrate. My brain felt as if it were slowly undergoing ossification, with the process pretty well advanced. As I stood looking out of my window, which commands a view of the Jersey hills, I felt an indefinable drawing. "Perhaps," I said to myself, and then I cast my eyes inquiringly on the tripod, that, too, seemed to say "Perhaps," and my camera really looked as though it were languishing for "a day out." So I at once set about packing-up, not enthusiastically, but with a feeling that I must have a change in order to stop this transmutation of my brain into molten lead. Half an hour afterwards I was on the Weehawken ferry boat.

I had somehow got the impression that at Weehawken I could take the cars up the river—the present station had not then been built—for a dozen miles or so, but I soon found out my mistake. I made inquiries, and found that there was no station and no railroad, and that I had wandered into a section of Deutschland. Not even a condemned vessel was in sight on which to try my "prentice hand," nor a specially ragged netchin to griu at me while I took his picture. Here was a dilemma indeed. Shanties there were, but they were dreadfully commonplace. In my despair I sought information in a beer saloon, which seemed to be so filled by a leviathan of a woman and an ichthyosaurus of a man, that there was hardly room for me to sit down. They paid no sort of attention to me at first, regarding me, perhaps, as a peddler wanting to barter his wares for Schweizerkase and Schwarzes Brod.

"Is there any stable near by?" I ventured to ask.

"Nein," replied Leviathan, in a voice which seemed to say that I was in good condition to be served up as Kalbfleisch.

"But," I persisted, "isn't there a horse in this region I can hire?"

"Only one, and be list mein," answered she.

"Could you have him tackled up, and convey me to the nearest railroad station?" I asked.

"Yah," very deliberately; "p'raps."

"How much?"

She looked at me, wondering whether I was peddler or prince, and then, as though she had struck an average, replied, "Two tollar."

"Good! Fetch him along, and I'll be off."

The boy driver and I reached Schnetzen Park in due time, traversing the dreariest road, and meandering through acres of swamp.

"Good place for fever and chills," I suggested.

The little sphinx at my side gave the horse a resounding blow with his whip, and simply answered, "You bet!"

When we reached the park I persuaded the youth to stand at the horse's head, and in a few minutes I had a picture of the funniest boy, the largest horse, and the most dilapidated wagon imaginable.

Then came the hunt for subjects. I saw a group of men standing on the platform of the station-house, so I brought my lens to bear on them, and cried out, with true professional emphasis, "Gentlemen, one instant, if you please."

One, two, three, and the work is done. "Thanks, gentlemen;" and I began to pack up.

Then I took a bit of winding road, at a point where two arching trees interlaced their branches, and it was no sooner done than up came a troop of wild, laughing girls from the silk factory, on their way to lunch. They gathered about me like so many bees.

"Shall I take you girls?" I asked.

Such a scream! and off they scampered. The feminine gender, however, has peculiarities which no mere man can comprehend, and in a few minutes they came rushing back, stood together in a very pretty group, and said, in chorus, "Mister, you may. Of course I complied."

By this time I was tired, healthily and gloriously tired. The sun was bright, the air was brisk and fresh, and the appetite, which had been dormant, began to resemble that of the *Uroa Americanus* in the spring, after winter's hibernation. My whole interior being—moral, physical, and intellectual—began to feel the effects of the tramp and the new experience, and I almost renewed my youth. I am assured that a photographic apparatus, with its delightful allurements, is a more valuable possession than Aladdin's lamp, or an ounce vial of the alchemist's *elixir vite*. Well, I had just one dry plate left. I was wondering what I should do next, when I heard a voice behind me, attuned to the true Celtic accent.

"Say, misther! say, misther!"

I turned to find a youngish woman, meanly clad, but with a bright gleam in her eye and great eagerness in every feature.

"Well, my good woman, what is it?"

She summoned all her resolution, and while the blood mantled her cheek, she asked, with an outburst of motherly affection, "Misther, will ye tak me babby?"

I confess to being touched by the pathos of that appeal. I had suddenly come into contact with a genuine bit of the best kind of human nature. Of course I melted at once.

"It will give me great pleasure, madam, to take a picture of your baby," I answered.

She actually cantered on her way back to the shanty which the husband and child had converted into a home. One thing, however, and a very important one, she had altogether forgotten. It did not occur to her, so great was her eagerness, until she nearly reached the house, and then she came to a standstill as suddenly as though she had run against a stone wall. I felt in my heart that some strange contiguity had arisen, and the feeling was confirmed when, with pathetic tremulousness, she cried out, "Misther, how much will it be?"

The desire to have the picture of that "babby" had partly crowded out the fact that this is a mercenary world. I determined that the mercenary side should not be visible on this occasion at least, so I screamed back, "Nothing, madam; nothing at all."

She started once more into the canter, but I heard her say, "Thank God, chape enough!" and I chuckled to myself at being taken for a professional, seeking the dimes and quarters of poor people.

I took both mother and child, and the picture is one of my best, and also one of my most valuable souvenirs of travel.

When I reached my study in town I was thoroughly worn out and jaded. The sun had dipped below the Jersey hills which made my horizon line, and I was gloriously and refreshingly used up, with a five hours' jaunt behind me. I had a good story to tell my friends who called in the evening, six pictures which I wouldn't part with for money, and the precious memory of a happy mother's face. The fresh air was in my lungs, and that night I slept the sleep of a man who has done his duty to his fellows and to himself. When I wrestled with the tangled problem the next morning, I was surprised to find that it was not so much of a problem after all.

I have but one bit of advice for all men of sedentary habits, viz., go and do likewise.

GEORGE H. HARWORTH.

—Harper's Monthly.

INVISIBLE STARS.

ST. GEORGE'S HALL, London, was crowded on Sunday afternoon, when the last of the first series of lectures to be delivered under the auspices of the Sunday Lecture Society was given by Sir Robert Ball, F.R.S., L.L.D., the Astronomer Royal for Ireland, on "Invisible Stars; the Use of the Camera in the Observatory." The lecturer commenced by describing how the number of stars visible to astronomers had been increased. At first about 6,000 were counted with the naked eye, but then on taking a small telescope places in which before only a few gleams of light could be seen were found to be studded with thousands of stars, while other places which had appeared to the eye quite barren, in turn glittered with innumerable specks, but even with the small telescope as many as half a million of stars could be discerned. On a mountain site, however, and using the largest and finest telescope procurable, it was seen that the stars numbered millions, and were as numerous as the population of one of the great nations of the earth. Even that, however, did not content the astronomer, as no matter how large his telescope was, he found there were yet points of light which were only just brought into view, and which indicated the existence of new stars. It was, however, impossible for opticians to give any more assistance, but photography had been pressed into the service with the most wonderful and satisfactory results.

An interesting description of the plates and telescopes and the methods of employing them followed, and was illustrated by a number of views exhibited by the aid of a lantern. The plates, which were so extremely sensitive as to be capable of receiving an impression in the one-hundredth part of a second, were placed in the telescope, and allowed to remain there in some cases for hours, the observer meanwhile using a twin telescope and keeping the portion of the sky under observation within range. When these plates were developed millions of stars which were before invisible, could be seen, whilst the most wonderful and important facts concerning others which were before entirely unknown had been ascertained. The action of the light from the stars was, of course, extremely slight, but as it was cumulative it gradually had its effect on the plates, and now at a very moderate estimate the number of stars known to exist was 100,000,000; but if his hearers in relating the points of his lecture liked to add a nought or two, no doubt they would be well within the truth. Each of these stars was probably a sun, and the centre of a planetary system like our own. Photography had also enabled astronomers to obtain some very beautiful views of the various nebulous bodies, some of which, including several photographs of the nebulae of Orion, Andromeda, and the Pleiades, were given on the screen. In attempting to give an idea of the immense size of these bodies, Sir Robert, speaking of one which, as it was shown on the screen, appeared to be nearly two feet in diameter, said the tip of his wand would cover a surface of something like two hundred millions of miles. The concentric rings which

were found round some of these nebulae tended to confirm the theory that they were gaseous masses of fire gradually cooling down, and would in course of time become suns and centres of systems of their own.

The lecture was listened to throughout with the greatest attention by a most appreciative audience. Next Sunday the first of the second series of lectures will be delivered by Mr. William Lant Carpenter on "The Wonders of the Yellowstone Park, the Recreation Ground of America."—*Chronicle*.

MY FIRST 'YACHT STUDY.'

EARLY in the summer I was asked by a friend whether I would care to spend a part of my holiday on board his father's yacht, in which he, with two of his brothers and some friends, intended taking a fortnight's cruise round the coast. I had made no arrangements for my vacation, which was then near at hand, and spoke truly when I said that I'd be delighted to take advantage of his kind offer.

'Don't fail to bring your photographic outfit along, old man,' he said, as we parted, after chatting further of the intended trip; 'you will be certain to find work to do with it. The fellows will ask you to take a group of them, or I'm much mistaken, and you must try, too, to get a picture of the *Go-ahead* for the governor. He intended giving the work to a professional photographer, but won't need to do that, I'm sure, now that you have promised to come with us.'

I had started photography only a year previously, but suppose that there were few more enthusiastic amateurs than I had already become. Commencing with 'baby' Willie, I had, within a week of the purchase of my 'kit,' exposed plates upon every member of our household, not forgetting (and I promise you that I, for one, shall not easily forget) 'Thomas,' the cat. The resulting negatives were not, in every case, entirely successful. The baby's, for instance, would have turned out much better had not the stupid little fellow lost his balance, and fallen from the table upon which I had seated him almost immediately I had removed the cap from the lens. In consequence of this mishap the picture necessarily suffered somewhat, as indeed (if one might judge from the absurd uproar he made) did Master Willie himself.

But these early attempts of mine have nothing whatever to do with the matter in hand. Mistakes in manipulation I had made without number from the very first, but in store for me there lay a far more serious trouble than any I had yet encountered, and it is of this that I want to speak just now.

Details of my meeting with the cutter's 'crew' would be out of place here, and, for the same reason, I omit all description of the first week of our 'voyage,' very pleasant though it proved to each of us.

I must say a word, though, about the groups. They were disposed of on the second day, but did not turn out as well as I could have wished. The two first were capitally sharp, but I unfortunately omitted to reverse my dark slide after exposing No. 1, and so took them both on one plate. Had it not been for this little slip on my part I believe they would have printed well. Nos. 3 and 4 were slightly out of focus; but, as I explained to the fellows, who did not seem altogether satisfied with the 'rough proofs' I showed them later, the fault, if indeed it could be so called, would tend only to give a more artistic appearance to the finished picture. They would notice, too, I went on, that it imparted an atmospheric effect seldom to be found in the finished pictures exhibited by professional photographers.

All this might be very true, admitted one of the men; but at the same time he thought that in this particular case the atmosphere had been somewhat over-done. 'Why,' he went on, 'I've been puzzling for quite a while as to whether I am represented here' (pointing to one of the prints) 'by this blur in front, or the smudge farther back towards the side.'

'The "blur," as you are pleased to term it,' I answered, 'is the foot of the mast, round which you will remember you grouped yourselves.' Then I saw that he was laughing at me, and, feeling a bit sore, went on, 'I should say that the "smudge" is your photograph, old man, and I'll ask our friends here if they do not agree with me in thinking it a most excellent likeness.'

This seemed to be a fit point in the conversation to air one of my pet art references, and I was not slow to take advantage of it. 'The true artist,' I said, 'invariably leaves something to the imagination of the spectator.'

'Then,' said he, with a quiet smile, the meaning of which I couldn't begin to understand, 'old fellow, I apologise! Looked at from that point of view, this picture of yours can put forward really the strongest claims to be called "artistic." The subject was then dropped.

We had dull weather for three days after this, and I almost hoped that the idea of photographing the yacht would be abandoned. No such luck!

'How will this morning do for your work?' asked the 'skipper' when the sun was shining brightly again.

'Well enough,' I replied, 'and if you'll make your preparations I'll set about it at once.'

It was finally arranged that I should take up my position in the 'dingey' which was being towed astern. My traps were handed over to me, and, after some difficulty, I managed to fix my tripod in the little boat.

'Are you quite comfortable?' shouted one of the fellows.

Now, standing, as I was, at the extreme end of the unstable little craft, a double dark slide under one arm, the other fully occupied with the

camera cloth, and much of my attention devoted to keeping the camera itself in position, I was in considerable doubt as to whether I really was feeling quite unconcerned and happy. But, not wishing to delay further (failing, in fact, to see any real advantage in so doing), I said all was right, and asked that the rope holding me to the cutter's side might be paid out. The tide was 'running strong' (I didn't even guess this was so until told of it afterwards by the 'skipper'), and with my head under the focussing cloth, doing my best to get the image centred on the ground glass, I was carried swiftly away from the *Go-ahead*. Just then I saw my picture—every line true and sharp, all as it should be—on the ground glass screen. This much I remember most distinctly, and I shall always believe that, had time been given me in which to decide whether the better negatives would be obtained by (1) 'exposing' before placing in position the slide carrying my plates, or (2) pushing the dark slide home to uncap the lens without first withdrawing the shutter of the former, that the result would have been—well, to say the least of it, surprising. But, alas! time for reflection there was none; and though interested as much, perhaps, as any one there in all that was going forward, I am not able to recall with clearness anything that happened immediately after the focussing of my picture.

The 'skipper'—and his word is borne out by the crew—told me later what it was that so suddenly cut short my operations. 'While you had your head smothered up in that black cloth,' said he, 'and just when you called out, asking us to "keep steady for a moment, please," the painter holding you to the yacht was drawn taut (the dingy having drifted away from us with the tide) and we saw you—by Jove, how scared you looked!' ('Yes; quite upset, poor fellow,' interrupted the man whom I had chaffed about his portrait in the group), 'that concertina-like square box, and the three sticks attached to its base, and the mahogany case you held under your arm—make a wild dive backwards over the stern of the boat. Our "first mate" here jumped over with a rope, and we soon hauled you both aboard, but I'm afraid, dear boy, that by this time your complete outfit's puzzling the fishes.'

'Yes,' I said, going downstairs ('below' is, I believe, the more correct term) to find a dry suit of flannels, 'and the "pro," will have to do the job after all. I've read often of its various manipulations, but until to-day had no idea that an instantaneous result was so easily obtainable by the so-called "wet process!"'

NOTES FROM NEWCASTLE.

Our local Society had before them at their meeting the other night a proposal for an exhibition of photographs at an early date, and a small Sub-Committee was appointed to consider the matter. I hope for a favourable report at the next meeting in December, but should have been more sanguine had the Committee been a little larger and somewhat differently constituted.

At the same meeting a collection of photographs, the result of the amateur photographer 'Hayfield' and 'Animal Life' prize competition, was shown; they do not call for much comment. Several new members were enrolled, and the new rule reducing the amount of subscription was passed.

The local craft have no reason to complain of business just now. Every photographer I meet tells me that business is splendid; very good; pretty fair; or not so bad: so I conclude things are prosperous.

I cannot congratulate the *Graphic* on their reproduction of Mr. Gould's photograph of H.M.S. *Victoria* gun trials; it does very little justice to the original.

Mr. Arthur Brown, artist, and one of the oldest of our photographers, gave his lecture on the yellowstone region (United States) the other evening at the Y.M.C.A. before a good audience, and illustrated the same with some capital slides, most of them reproduced from his own negatives and drawings, and very good they are. Mr. Brown is a capital lecturer, complete master of his subject, and full of anecdote. I have often wondered the Newcastle Association does not invite Mr. Brown to give a lecture before the members.

D. D.

Foreign Notes and News.

THE Council of the Italian Photographic Society are making arrangements for holding a public competition of instantaneous photographs, in which all amateurs, both Italian and foreign, will be invited to take part. All the views sent in will be exhibited at the sittings of the Society, and the public will be admitted. A special announcement will appear later on to indicate the exact date of the competition, in which so large a number of competitors have already stated their attention of taking part that its success may be looked upon as already assured.

THE Germans have been finding "Nuktigonia" out. Dr. Vogel exhibited the substance at the last meeting of the Verein zur Förderung der Photographie, *apropos* of which Dr. Miethe points out in the *Wochenblatt* that

the special tip recommended in the prospectus consists of employing a changing box with sleeve, a contrivance which, as he very correctly remarks, has been in use for the last twenty years. "One thus sees," continues Dr. Miethe, "that the whole business is neither new nor particularly ingenious, especially on discovering that Naktigonia is nothing but a concentrated solution of a well known reddish-brown azo colouring matter, otherwise known as 'Tripaolin.' This," he concludes, "ought to be sufficient warning to our readers to keep clear of the Naktigonia Company and their productions."

THE Circolo Fotografico Lombardo has opened an exhibition with the first of this month, consisting of the following divisions:—

1. Composition, landscape, architecture (size 13×18).
2. Studies from nature (sizes 9×12 and 13×18).
3. Instantaneous photographs (size 9×12).
4. General division, consisting of any exhibits displaying the application of photography to industrial and scientific purposes.

THE Bulletin de la Société Photographique gives an excellent receipt by E. Gosselin for reducing too intense negatives. The negative must be first washed for half an hour and then immersed in a bath of the following composition:—

Water.....	100 c.cm.
Sulphuric acid	4 "
Chromate of potash, solution three per cent.	6 "

The reduction takes place very rapidly without causing spotting; and subsequent intensification, if necessary, can be easily accomplished.

THE connexion between electricity and photo-chemical action has been now for some time thoroughly established as the result of a variety of observations. For instance, it has been frequently shown that when an electric spark has passed across an ordinary dry plate its path becomes visible on developing. Mons. Philippe Braham in a recent communication to the *Journal de l'Industrie Photographique*, has, however, shown that a magnetic action can, under certain circumstances, take place upon the sensitive film. Mons. Braham placed a rapid plate in the field of a powerful electro-magnet, the poles of which were fifteen millimetres apart. The circuit was then closed for a certain time and the plate subsequently developed. On development, a dark spot surrounded by a nebulous halo appeared at that spot through which a line joining the poles would pass. The discovery, which certainly forms an interesting contribution to the theory of connexion between the different molecular forces, will, it is to be hoped, be followed by others in the same direction.

ON December 14 Herr Theodor Primm, one of the best-known portrait photographers of Berlin, will celebrate the twenty-fifth anniversary of the establishment of his business. The occasion is to be celebrated in the convivial manner dear to the Teutonic heart.

MESSERS. GILLES and MESS. SCHNEIDER & Co., of the great Crenset iron and steel works, who recently electrified the industrial world by their plans for a proposed bridge across the Channel, read at the Paris meeting of the Iron and Steel Institute, have recently distinguished themselves still further by constructing a new photographic apparatus, which is a triumph of mechanical skill. It would be impossible to describe this rather elaborate device at length, but it may be mentioned that the camera can be pointed in all azimuths with equal facility, that the front and back portions have independent movements, that each of the three parts of the camera can be separately removed, and also pointed at different angles, and that the ground-glass focusing plate can be moved about quite independently of the camera box. The apparatus appears to be specially designed for taking architectural views.

A DAY IN THE PRINTING ROOM.

To speak of the printing room, in many cases, even in otherwise excellent and large establishments, is an euphuism, the glamour of which disappears the moment we cross the threshold of the doorway. I have seen a stable utilised for the purpose; also an underground cavernous den, where the water would occasionally well up through the floor and flood to the depth of two or three inches; a staircase at the top of the house; a rough tumbledown shanty in a corner of the yard, where the rain would pour in almost as through a riddle, &c.; and all these where a high-class and, in some cases, extensive business was carried on. Such things as these are disgraces which should be blotted out, for surely some means might be found to improve them out of existence. The poor printer is supposed to be able to flourish in any out-of-the-way corner, and to produce his things of beauty which are to provide joy, if not for ever, at least as long as they can reasonably be expected to remain so, under circumstances which in such cases are almost sufficient to tempt him to commit suicide; or, at least, to look upon photography as being the handmaid of despair.

In different establishments the printer's duties somewhat vary, as for instance, Mr. A. will only expect him to attend to the printing and its concomitants proper; but Mr. Z. will also expect him to work out all negatives for orders, spot them, put them into condition generally, assist in mount-

ing, spotting, rolling, &c. &c.; these, however, are but smaller matters, which we need not here stay to consider. We, therefore, will only take note of positive duties. These duties should really commence the previous evening by taking stock of the amount and character of the work likely to be required to be done; then strengthen the silver bath from a stock bottle kept for that purpose, and see that it is in a neutral condition. The ordinary strength of the silver solution should be about fifty grains per ounce of water, certainly not less than forty-five. After each three or four sheets have been prepared, add from the special stock bottle as much as will restore the bath to its pristine strength, remembering that each sheet will extract from it about twenty grains. See also that the albumenised paper, especially if it be doubly albumenised, as much as will be required for use, is put into an absolutely cool and, if possible, damp place; the reasons for which, as well as for other things herein stated, I cannot enlarge upon here further than to say that my experience of twenty-six years has shown me how necessary they are under many circumstances for successful and harmonious work. Strengthen the toning bath, too, with gold solution, so as to ripen for the next batch of prints, always keeping two working baths, and using them on alternate days. I have never found anything, in all things, to equal the old acetate of soda bath, consisting of three grains to the ounce of water. For stock solution to strengthen with, I put one ounce of acetate of soda and two tubes of gold to eighty ounces of water. This, too, keeps up the quantity of the bath, and allows the sludge to be cast aside, which may be allowed to accumulate in consideration of the residues.

Commence the day's labours with the preparation of the paper, in the intervals of which place the fresh negatives in proper frames, fitting up vignettes, &c. &c. Every printer, of course, knows the details of these things, but system is half of the work. When the paper is dry, carefully roll it all up, surface outwards, on a clean roller, with clean hands, keeping it in a cool place, and taking it off sheet by sheet as it is required for use. Cut it all up, especially that to be used for portraits, in one direction of the sheet, the lengthway of the sheet to be used upright in the frame; that is to say, from head to foot of the portrait, as when wet it expands more in one direction than the other, producing in some cases manifest distortion of the features. If it be possible, let all the printing be done in the shade, but especially portraits and thin negatives. For dense negatives, but particularly those showing violent contrasts, it is better to prepare the paper upon a weaker bath; and inversely for weak negatives, it should be prepared upon a stronger bath, say quite twenty-five grains less and more per ounce each way. In winter, when the light is feeble and bad weather prevails, the sensitive paper will speedily discolour, especially when two or three days are required for one print. Backing it up in the frame with sodic paper will wonderfully preserve it, but is somewhat troublesome, as it absorbs moisture from the atmosphere, and will be in danger of ruining the negative; therefore, it must occasionally be taken out and dried before the fire. Backed up, too, with old and discoloured silver paper will greatly assist in keeping it in condition, and is not any further trouble; but if, notwithstanding, it should become much degraded, even until apparently worthless, it may be saved by putting it, before toning and afterwards, into water which contains about one to fifty of its quantity of ammonia, and also a little ammonia in the bath: the restoration is truly wonderful.

As the prints are taken out of the frames, keep them flat under pressure, the advantage of which will be found when the operation of trimming comes into hand, which should be accomplished before toning, as it saves both time and gold, and is then more easily and readily performed. In cold weather keep the toning baths and, in fact, all solutions, which have to be used in connexion with the prints in a tolerably warm place, as then their action is more free, even, and successful. Even in the preparatory washings see that the water is not absolutely cold, both for comfort and keeping all things in an even balance. Put them into the water one by one, changing it repeatedly, until no further milkiness is observed; for the more perfectly the silver is washed off previously to being toned, the less they will change in colour when placed in the hypo. When well washed, put them for a few minutes into water slightly acidulated with glacial acetic acid, rinsing them again before toning; from the toning bath drop each print into salt water, as it prevents the further action of any gold which is carried with them. See that the fixing bath is neutralised from any possible taint of acid by adding to it, say, half an ounce of liquor ammonia, which will also exist in quelling any insubordination in the shape of blisters. This bath should consist of two ounces of hyposulphite of soda to each pound of water. Allow the prints to remain in this solution not less than a quarter of an hour, keeping them in motion all the time; as, in fact, they should be in every operation, with plenty of room to move about freely. When properly fixed, never lift them out of the bath nor pour it out from them, but have salt water of the same temperature in readiness, gently pouring it into the dish and gradually flooding the hypo out; then, after a few minutes, let the water through a pipe from the tap also gently flow through them, so that the change of heat be not violently arrested, when they may be finally disposed of to wash for the night. Having prepared the hypo for the following day, proceed as previously directed.

Let every operation be conducted with the strictest regard to cleanliness, and let there be a perfect isolation of every chemical, in solution or otherwise. Keep the hands scrupulously clean and dry, and see that

every utensil is well washed out, both after using and before using again. Have a separate dish for every purpose, and let it not be used for any other. I have seen in a large place of business one dish used for every operation but that of toning. What wonder if stains should appear, or even a whole batch of prints be ruined? And the proprietor of that establishment had a well-deserved reputation throughout England.

Let all things be done with care, assiduity, and intelligence; and let both master and servant continually bear in mind that in no small degree the credit and reputation of the business they represent are in the hands of the printer, even though he be relegated to a "back slum," and but too often the recipient of the splenetic wrath of those that surround him.

G. H. E. SUTTON.

[The foregoing was written for the ALMANAC, but being received late had to be considerably condensed. We now give it in full.—Ed.]

Our Editorial Table.

THE ART OF RETOUCHING NEGATIVES AND FINISHING AND COLOURING PHOTOGRAPHS.

By ROBERT JOHNSON. (London: Marion & Co.)

ALTHOUGH not so stated in the volume itself, this book is really a second edition of the one which, under the same name, was published by Messrs. Marion in 1886, being enriched by the addition of eight extra chapters, which refer to artistic composition, and which occupy between forty and fifty pages in themselves. We may here reiterate that the portion of the work devoted to retouching is written in a very lucid style, and the various working directions are given with full detail, the whole being enriched by numerous illustrations, and tending to make a good retoucher of any one who will take the pains to read and carefully study the work and follow the directions therein given. In the portion devoted to artistic composition, Mr. Johnson endeavours to answer the question—"You say such a photograph is artistic and such another is the reverse. Why is the one artistic and not the other?" In his chapter entitled "The Eye Compared with the Lens and Camera" the author does not quite show his realisation of the fact that the portrait lens, equally as much as the landscape lens, shows everything in perspective, and that the representation of the front elements in a group of persons on a scale very much larger than those at the back does not depend upon the employment of any special class of lens, but is a necessity of linear perspective. Many useful hints can be obtained from the chapters on "Accessories," "Perspective in Backgrounds," and "Simplicity in Composition," and we commend their perusal, together with the other portion of the work, to our readers.

WE have also received from Messrs. Marion *Revised Formule* for the production of transparencies, by which cold, warm, or extra warm tones can be obtained at pleasure, either on Cowan's chloride contact lantern plates, or on chloro-bromide plates.

FURTHER, and from the same firm, we have received one of their "Norser" vignettters, which is capable of printing a vignette of any size within the limit of the frame for which it is intended. By adjustable masks the opening is adapted to the shape of the print desired, while provision is made to place these as near to, or far from, the negative as considered desirable. When once fixed and adjusted, which occupies only a few seconds, it serves for an unlimited number of prints.

MR. A. R. WORMALD sends us samples of some "symmetrical" lantern masks he is issuing. In these we are glad to see that he has adopted Mr. Pumphrey's system of having one side of the mat white, while the other is black, by which the "sorting" of the slides is facilitated. Mr. Wormald adopts various forms of aperture.

PATENTS COMPLETED.

NEW OR IMPROVED HOLDERS OR LIFTERS FOR PHOTOGRAPHIC PLATES, FILMS, AND PAPERS.

No. 7675. THOMAS STANWAY, 24, Cauldon-road, Hanley, Staffordshire.—*November 9, 1889.*

My invention relates to holders or lifters for photographic plates, films, and papers; and my said invention has for its object a new or improved method of constructing same, whereby said plates, films, and papers may be easily manipulated without risk of injuring them.

My invention consists in making holders or lifters for photographic plates, films, and papers, in the form of loops which fit on the ends of the plates. Each loop is made with a suitable handle or finger hole to lift it with, and also with one or more stops to keep said holders or lifters at the ends of the plate being manipulated.

In using holders or lifters constructed according to my invention, one is held in each hand and slipped on the ends of the plate. The holders or lifters are then slightly pressed towards each other to prevent them slipping off the plate. The plate is then manipulated in the ordinary manner. When they are used for papers and films, said papers and films are first damped and laid upon a sheet of glass, and manipulated as before.

Claim:—A holder or lifter for photographic plates, films, and papers, constructed in the form of a loop provided with a suitable handle or finger hole to lift it by, and one or more stops to keep it in position, substantially as herein set forth and shown.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 28.—Mr. Archer Clark in the chair.

MR. P. EVERETT discoursed on the subject which had been announced for the evening—*The Action of Ferricyanide of Potassium on Developed Negatives*. He said that an experience which he had had two years ago had caused him to take the matter in hand. He had wished to make a positive by superposition, and had trusted to rapid opening and closing of the dark room to give the exposure. The negative proved, however, to be greatly over-exposed, probably on the point of reversal; on this he added, as he supposed, more pyro to the developer, and, to his surprise, found the image gradually disappear. He then found that he had taken, in mistake for pyro, a solution of ferricyanide of potassium; so he rinsed the plate and applied fresh developer of pyro and alkali. An image then reappeared, but this time it came not as a positive, but as a negative, although printed from a negative. The plate was foggy and weak, but the result (which was shown) struck him as being so peculiar that he had preserved it and endeavoured to trace this action of the ferricyanide. He had started by immersing a negative in a solution of ferricyanide. There was an action, but it took a very long time to complete—about thirty-six hours. He then repeated the experiment with the addition of a small proportion of bromide of potassium. The image was now changed in about a quarter of an hour. He had also repeated the experiment with iodide and with chloride in place of bromide; in each case the conversion was sufficiently rapid, but the chloride was much slower than the bromide. He then tried redeveloping with pyro and sulphite, and found that the bromide and chloride films rapidly yielded, but the iodide did not. There was a difference in the results obtained with bromide and with chloride. With the latter the image redeveloped darker and browner in colour, and he thought, therefore, that if the original negative had been a grey one it would be found to have gained in printing density. Another point which he had noted was, that with a plate which gave much iridescence this iridescence disappeared when thus bleached and redeveloped, enabling one to satisfactorily use plates which, from age or other cause, were liable to this defect. The plates shown illustrating the various experiments had been treated with a mixture of one ounce each of ten per cent. solutions of ferricyanide of potassium and bromide, chloride, or iodide of potassium, as the case might be, diluted with two ounces of water,

and, with one exception, they had all been exposed for twenty-five seconds at a distance of five feet from an ordinary gas burner. The exceptional plate had been exposed for four minutes at the same distance, and would illustrate the advantage of special treatment for such a case of gross over-exposure. This particular plate flashed up, of course, in the developing, and was then washed and bleached with the mixed solution of ferricyanide and bromide. It was again washed and a fresh developing mixture applied containing five times the normal amount of pyro and but little ammonia. There was now so much density that it had to be reduced after fixing with ferricyanide. It would be seen that this transparency, although so much over-exposed, was the densest of the series.

Mr. W. E. DEBENHAM inquired whether Mr. Everett had tried the bromide treatment without ferricyanide for saving an over-exposed plate. That was a recognised method, and it would be interesting to know by a comparative experiment what influence was due to ferricyanide in this case.

Mr. EVERETT had not made the comparative experiment referred to.

Mr. G. W. ATKINS inquired whether the colour of the bleached but not redeveloped negatives was permanent.

Mr. EVERETT replied that at all events it was so for some weeks.

The CHAIRMAN said that in that case the solution should prove to be a good reducer instead of bichloride of mercury, which was sometimes used for the purpose, but the results of which changed in the light.

Mr. A. HADDON remarked upon the yellow stain which appeared upon the plates that had been submitted to the treatment described, which stain was characteristic of ferricyanide.

Mr. A. COWAN said that that was so, but that it could be removed by acid.

Mr. EVERETT said that he should like to have an explanation of the reversal of the image in the plate which he had first shown.

Mr. HADDON would explain it thus:—The plate had been, owing to over-exposure, subjected throughout to the action of the light; the upper portion of the film had, however, developed first, and to depths corresponding to the amount of action of the light. When washed and treated with ferricyanide and the bromide contained in the developing solution the reduced silver had been restored to its original unexposed condition, so that when a fresh developer was applied the lower portions, having been affected by light generally, developed up to form the reversed image. He added that Mr. Everett had set a good example in retaining, instead of throwing away, the result of an abnormal experience, and bringing it forward at that Association.

Mr. DEBENHAM fully concurred in the last remark, also generally in Mr. Haddon's explanation of the reversal of the image; but he thought the explanation might be supplemented by the suggestion that the action of the ferricyanide and bromide was more rapid upon the developed image than upon the exposed but as yet undeveloped image. Ferricyanide and bromide was supposed with the latter to restore it to its original unexposed condition, but if it had done this as rapidly as it converted the developed image, Mr. Haddon's explanation would not hold good.

Mr. HADDON acquiesced in Mr. Debenham's suggestion, and the meeting terminated with a vote of thanks to Mr. Everett.

CAMERA CLUB.

On Thursday, November 28, the usual monthly exhibition of lantern slides took place at the Camera Club. A very large number of slides were brought up by members.

Mr. Elder exhibited a series illustrating the River Thames from London round to the Essex coast, giving an interesting description with the photographs; Mr. Hansard contributed pictures of Spanish and Algerian life, scenery, and architecture; Mr. Laurie, some instantaneous views; Mr. Howlett and Mr. Williams, sets including very excellent work; Mr. Rodgers, slides from negatives taken on the Down-river Excursion; and Mr. Humphrey, transparencies from hand-camera negatives, including one picture of a scene by the St. Gothard Tunnel, very weird in character. Capital slides were shown also by Messrs. Pemberton, Sands, and Charters White. A few sent by Mr. Gale concluded the exhibition.

The subject on Thursday, December 12, will be *Tinting Shutters*, when Mr. Charlton Wollaston will open the discussion.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE annual meeting of the above Society was held at the Club Rooms, Grand Hotel, Colmore-row, on Thursday, November 28, Mr. W. Jerome Harrison, F.G.S. (Vice-President), in the chair. There was a large attendance.

The HON. SECRETARY (Mr. J. H. Pickard) read the annual report.

The average attendance at fourteen oratory meetings held at the new rooms has been seventy-four, and at three at our late room, sixty-three.

The papers read and special meetings held during the year were as follows:—*A Tour in Italy and Switzerland* (illustrated with lantern slides), A. Pumphrey; Special Meeting (new rooms); Lantern Display (members' slides), Lantern Committee; *Daguerotype*, W. S. Horton; *Kodakian*, W. Griffiths; *Photomicrography*, J. Hall Edwards; *Holiday Trips with the Camera*, E. H. Jaques; *Various Printing Processes*, W. Griffiths; *Lichenhead and Ulster* (lantern slides), Lantern Committee; *Cameras and Appliances*, B. Karleese; *Composition*, C. T. Cox; *Platinotype*, J. C. Huxley, M.D.; *Portrait Painting as applied to Photography*, J. J. Scatchall; *Light, Stops, and Lenses*, J. Edmonds; *Lantern Slide Making*, E. H. Jaques; *Lenses and Stops*, W. Griffiths; *American Lantern Slides* (per favour of Camera Club, London), Lantern Committee; *Hints to Beginners*, E. C. Middleton.

The Annual Exhibition was held in the Young Men's Christian Association's rooms, Needles-alley, on December 14, 1888. There was a good attendance of members and their friends.

The annual exhibition for 1889 has been unavoidably postponed until January, 1890.

Special rules have been issued by the Council for the government of future competitions.

During the season of 1889 fourteen excursions were arranged for. Prizes were offered by Mr. W. J. Harrison (Shakespearean Villages), Mr. J. H. Pickard (Dovedale), and Extension Committee (Shrewsbury), for the best pictures

taken upon the whole-day excursions. Bearing in mind the experience of past years, the Committee suggest that the number of excursions be materially reduced, and consider it desirable to limit them to one per month.

Your Lantern Committee has pleasure in reporting a successful year, with a numerous attendance at all meetings at which the lantern was the prominent feature, showing that this method of exhibiting photographs is becoming one of the most popular.

A letter was read from Dr. Hill Norris:—"It is with great regret that I feel myself compelled to resign the Presidency of your Society, which I have held uninterruptedly since its foundation. The cases of medical practice and the pursuit of original work in the brief intervals of leisure which the former affords leaves me but little time or strength for public life. I feel, too, that your ship has now grown to such dimensions as to require not only good subordinate officers, but also a captain at its head capable of carrying it through all weathers; this I am no longer equal to; and if you will allow me to retire in favour of younger blood, and come among you occasionally as an irresponsible social unit, freed from the tension of official position, I shall feel very grateful. Wishing the Society every possible success in the future, I am, yours faithfully, RICHARD HILL NORRIS."

Resolved, "That Dr. Norris's resignation be accepted with regret, and the hearty thanks of the Society be given to him for his duties as President for the past five years, and that Dr. Norris be elected honorary member of the Society."

The election of officers and Council was next proceeded with, and the result is as follows:—*President*: Mr. J. B. Stone, J.P., F.I.S.—*Vice-Presidents*: Messrs. W. J. Harrison, F.G.S., E. H. Jaques, and B. Karleese.—*Council*: Messrs. J. J. Buntin, A. A. Bonehill, W. S. Horton, S. G. Mason, E. C. Middleton, Dr. Nicol, William Rooke, and G. A. Thomason.—*Librarian*: Mr. S. J. Holliday.—*Treasurer*: Mr. T. Taylor.—*Hon. Secretaries*: Messrs. J. H. Pickard and A. J. Leeson.

Votes of thanks were given to the Treasurer, Librarian, Mr. Rooke (late co-Secretary), and Mr. J. H. Pickard, for their services during the year.

Mr. W. S. Houghton (Exhibition Committee) stated the postponement of the date of the exhibition till January, 1890, was owing to structural alterations being made in the building where the same will be held, and that circulars announcing date and particulars will be posted in a few days.

The HON. SECRETARY read a circular calling attention to a special meeting of the Society on December 11, when Mr. W. Jerome Harrison, F.G.S., will read a paper on *Photo-surveys*.

On the proposition of Mr. A. A. BONEHILL, that a subscription should be made towards the fund for a lantern, a number of members present subscribed together a sum of over 10*l*.; this, with the fund in hand, leaves the Society with over 14*l*. towards the purchase of a first-class optical lantern. Resolved, "That members be solicited to add further subscriptions to enable the Council to provide a lantern at once."

BATH PHOTOGRAPHIC SOCIETY.

NOVEMBER 27,—Mr. W. Pumphrey in the chair.

Miss Ashley exhibited a number of large direct photographs representing scenes in Colorado, Wyoming, and Mexico, the work of Jackson, of Denver.

Mr. FRIESE GREENE drew attention to developed prints made with an emulsion containing starch. He complained of the suken appearance, and attributed this to the base or coated surface being unsuitable.

Mr. J. Dutton showed some old wet-plate negative films transferred from glass to paper.

Circulars anent the formation of a Photographic Institute were distributed, also copies of *Scripts* and other trade price lists, which had been sent for that purpose.

Mr. H. M. SMITH, lecturer and demonstrator for the Eastman Company, then discoursed upon the subject of *Enlarging on Bromide Paper*. He commenced by describing the methods of illumination available, giving preference to an arc lamp of two-thousand candle power, next in sequence the oxyhydrogen jet, then paraffin containing a small proportion of camphor. When daylight is used, a darkened room where light can be admitted from the north was said to be preferable. Then an ordinary camera could be used, it being merely necessary to insert the negative from which an enlargement is desired in an opening just large enough to admit of it and through which light is allowed to enter. Then the adjustment of distances—camera from negative, and camera from focussing screen—was easily found, either by the tables in the *Year Books* or experiment. The question was often asked whether an ordinary magic lantern was suitable for making enlargements, and he answered yes, if the negative is not over three inches in diameter and the lantern is fitted with condensers of four and a half inches diameter; but if it be desired to enlarge from a half-plate, then the condensers ought not to be less than eight inches in diameter. Attention was drawn to such details as warming the apparatus before use, the result of a smoky flame, and of oil spilt about the burners, the advantage of a rectilinear type of lens, and the employment of a negative fully exposed. Under-exposed negatives, said the speaker, are no good at all for the purpose, they are sure to give a chalky-looking enlargement. The question of permanence was then dealt with, and the chances of fading from well-recognised causes plainly laid down. Supposing the paper to be a pure sample, the emulsion pure, and the manipulatory details which follow exposure carefully carried out, there was no reason why silver prints on bromide paper should not last as long as any other. Mr. Smith then explained the processes of developing, clearing, fixing, &c., and demonstrated these before the audience. Finished specimens were also handed round. Mr. Smith next drew attention to the new celluloid negative films which the Eastman Company will shortly place on the market. They appeared to be about the same thickness as the well-known "stripping film negatives," but more transparent and of less weight. The advantages of the new Kodak detective camera were also explained; there are several improvements in construction of lens, shutter, and general get-up.

The CHAIRMAN hoped that celluloid would replace the paper in the roll holder; it would be much more easy than the plan of film stripping, without increasing the weight, a most important consideration with tourists.

Several questions were then submitted and replied to.

The CHAIRMAN having formally thanked the lecturer, an adjournment took place to the dark room, where an enlargement was made by means of an optical lantern, and developed, &c.

The next meeting will take place on December 18, when the President will give an illustrated lecture on *The Cities of Italy*.

At the thirteenth annual exhibition of vacation sketches and paintings, opened at the Jubilee Hall, Bath, December 3, the special prizes awarded to pupils studying at Mr. Harbutt's Art Studio for series of artistic and skilful photographs were as follows:—First prize, Mr. G. Thomas; Second prize, Mr. J. Stillman Gill. Messrs. W. Pumphrey and W. M. Ashman adjudicated.

BRIGHTON PHOTOGRAPHIC SOCIETY.

NOVEMBER 26,—Mr. D. E. Caus in the chair.

The evening was devoted to an exhibition of pictures taken with detective cameras and also of detective cameras, seven being contributed by Messrs. Harcastle & Co., and several members showing theirs.

The next meeting (December 10) will be a lantern night.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The twenty-sixth annual meeting was held in the Association's Rooms, No. 3, Lord-street, on Thursday, November 28. The President (Mr. A. W. Beer) occupied the chair. There was a large number of members and friends present.

The following gentlemen were elected members of the Association:—viz., Messrs. John Woolfall, R. McGowan, and R. H. Webster, L.R.C.P.

The Treasurer's report shows a balance remaining to the credit of the Association of 48*l.* 13*s.* 8*d.*, after investing the sum of 194*l.* 14*s.*, and writing off 14*l.* 5*s.* 4*d.* as depreciation on club-room furniture, &c.

From the Secretary's report, there has been an accession of seventy-four members during the year, this being the highest number of new members since the formation of the Association. There are now two hundred and thirty-eight members.

The following gentlemen were elected as officers for the coming year:—viz., President: Mr. Paul Lange.—Vice-Presidents: Messrs. William Tomkinson and W. D. Mead.—Auditor: Mr. A. Bradbury.—Librarian: Mr. J. McDonald Bell.—Treasurer: Mr. Joseph Earp.—Secretary: Mr. Walter Hughes.

The competition prints sent in by the members had been adjudicated upon by the following gentlemen:—Messrs. G. W. Webster, John Finnie, and E. R. Dibdin, who had awarded the Association's medals as follows:—"For pictures (in sets of six) over half-plate size," Messrs. J. L. Mackrell and D. Cunningham. "For half-plate and under," Messrs. T. B. Sutton and William Tomkinson. "For set of two enlargements," Messrs. F. K. Glazebrook and J. L. Mackrell. "For the best single picture," Messrs. F. Anyon and J. L. Mackrell were bracketed equal in merit.

Lantern slides were judged by Messrs. G. E. Thompson, E. L. Grundy, P. Lange, and W. D. Mead, medals (for the best and second-best set of six) being awarded to Messrs. A. J. Cleaver and T. B. Sutton.

The whole of the slides (one hundred and thirty-eight) were then shown in the lantern.

Announcement was made that a "Social" or smoking concert would be held on Tuesday, December 17, at half-past seven p.m. A nautical sketch, entitled *All at Sea*, written and arranged by Mr. A. J. Nicholls, would be given. Also that the celebrated pictures of Mr. H. P. Robinson (Tunbridge Wells), consisting of about seventy frames, would be on view in the Rooms, No. 3, Lord-street, from December 16 to the end of January.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

NOVEMBER 6,—The President (Mr. Frederic Graff) in the chair.

After the exhibition of two Eastman cameras, and the election of new members, Mr. JOSEPH M. WILSON related some interesting experiences in connexion with a trip made through several European countries during the past summer. He carried with him a Scovill hand camera and material for about seven hundred exposures, most of which was made use of before his return. The camera, in which several ingenious modifications and improvements had been made by Mr. Wilson, was shown, and also a light and convenient alpenstock tripod of his own design, which had been carried throughout the trip.

Dr. C. L. Mitchell showed a Blaf Compact Camera mounted on a single leg or "Unipod," for use in instantaneous work in situations where a regular tripod could not conveniently be set up, and where more steadiness was desirable than could be maintained by holding the camera in the hand. With a large camera on board a yacht, or in street work, when setting up a tripod would attract a troublesome crowd, the unipod had been very useful.

Mr. Wilkinson showed Dr. Krüger's hand camera obtained by him in Germany.

Mr. FRANCIS BURROWS also showed a new hand camera of his own design, which he described as follows:—I present to you this evening another candidate for your favour, "The Ultimate," a 4×5 hand camera. It is compact, measuring 5×5½×9 inches, and yet, by drawing out the telescopic front, it will accommodate an eight-inch focus lens. The front of the box opens, allowing access to the lens and shutter, while in the rear of the lens a flap shutter may be closed during this operation. This box is fitted with a 4×5 pantagraph lens of five and three-quarter inch focus, and working *f*-6 approximately. The shutter is of the rotary type, but is peculiar from the fact that its movement is always in the same direction. A small crank on the front board sets it by a part revolution, and a little farther movement of the same exposes; by this means the shutter is set without exposure of the plate, and generally at the last moment. With the spring at this tension the exposure is rapid enough to make all ordinary work, including landscapes, marine views, or animals. However, the shutter disc is double, and by releasing this small catch one-half may be revolved independently of the other, thus, you see, making the effective opening in the shutter one-half, one-quarter, or one-twenty-fifth of its full size, and so giving the same fraction of the ordinary time of exposure. By releasing the spring the disc may be entirely revolved by hand, and the

exposure timed. The opening and closing by this method being one simple movement, it is practicable to make the exposures very short. On the bottom of this box you will notice a tripod plate and fitting for a finder. They do not belong to the box, but were placed on this, my model, for experiment. For those who wish such additions nothing can be more simple. The rear compartment, opening at the bottom, contains a new locking arrangement, which holds one plate holder rigidly in place, while the other three drop loosely in back of it. A slight pull on this lock loosens the plate holder and lifts it out, while a strong pull draws the entire mechanism from its place, and makes place for a 3½×3½ Eastman roll holder, which slides into its bed with slight pressure. The plate holders are of new design, very small, and of metal; they are double, and are loaded by removing both slides and the moveable plug from the top. As any lens from four and a half to eight inches in focus may be fitted, the question of focussing comes up. With this lens the front is drawn out about three-fourths of an inch, and there is a line drawn. In this position the lens cuts sharply to within about twenty feet. With an *f*-8 or *f*-11 stop everything beyond this distance is very sharp. Practically, I make all views at this point. About one-sixteenth of an inch back of this is another line. When drawn out to this we get better foreground effects, but the horizon will not be quite distinct, and should not be allowed to show unless it is possible to use a stop, as for instance, a well-lighted subject, or one allowing time exposure. In case I find it necessary to time a plate I am generally able to find something to place the camera upon—a railing, bench, or stone; or I have made very sharp photographs of several seconds' exposure by holding the box firmly against the side of a house or tree. For those who will carry a tripod I can suggest nothing better.

Correspondence.

SAMUEL FRY & CO., LIMITED.

To the Editor.

SIR,—We are informed by several customers that representatives of competitive firms are circulating the report that we are no longer undertaking the production of argentic-bromide enlargements, for which we have obtained some reputation.

We ask the advantage of your wide circulation to state that this is a most unscrupulous attempt to injure our business, and that the report is absolutely devoid of a vestige of truth.—We are, yours, &c.,

SAMUEL FRY & Co., Limited.
A. E. HAYMAN, Secretary.

EXHIBITION MATTERS.

To the Editor.

SIR,—I have read with pleasure the correspondence on the above subject by "Old Medallist," and would like to make a few remarks and give my experience as a young exhibitor who has not yet received a medal. This year I sent some pictures to the Exhibition, and although they were taken direct on plates 18×15, received no notice whatever in your JOURNAL. Four were hung, but would have been just as well at home, with one exception. This one being about knee-high, could sometimes be seen when not eclipsed by trousers or skirts; the remainder (all landscapes) being all "skayed," could scarcely be seen.

This year the Exhibition has been a great success as regards the number of visitors and the money taken, and, if the Exhibition is to continue so, I am convinced that steps must be taken by the Society to secure a larger room, or limit the amount of wall-space to each exhibitor, so that more justice can be shown to all whose exhibits are worth hanging, only a few being now seen to advantage as at present hung; and, as previously remarked by a correspondent, exhibitors' pictures are separated, except a favoured few and those who take the precaution to frame their exhibits in one frame. I also had half the number sent for exhibition "Middlesex Hospital way" (one rightly so, having had the glass broken in transit); not from any desire, I should think, of the Hanging Committee to disqualify them, but crowded out, I should imagine, as I received them back with numbers on the glasses, as though they had been catalogued and then displaced by later exhibits received.

I also notice with regret that preference is not now given by the Judges to photographs "untouched," but to artistic productions more or less produced by the paint-brush. This is, I think, a retrograde movement, which will not tend to improve the photographic art. I noticed also a picture conspicuously marked on the frame as untouched with a rose leaf painted in. Such representations as these may deceive some. Such photographic "lies," I think should hardly be allowed to be hung, especially on the line, as a deceiver to the innocent public.

I also think it would be well not to award medals to exhibits that have been taken for some length of time and on sale by the dozens. Such an example I also observed this year, it being an enlargement on "bromide paper" from a negative, prints of which have been on sale in London for about two years; so at least I was informed by the printseller in the City, from whom I bought a platinotype 10×8 print for 2*s.* 6*d.* of the identical picture (*Head of Derwentwater*).

Names and addresses inscribed on the pictures, I think, would be better omitted altogether until after the awards were made, and then, if attached afterwards to the exhibits, should be the privilege of all, and would save visitors a great deal of reference to catalogue. I think, if I remember right, that this rule was overlooked in the medal pictures, *Artists at Home*, the full business address appearing on each picture.

Provincial exhibitions are not yet all that could be desired. One matter I have in mind in connexion with the last Cornwall Exhibition, referred to in a previous letter, i.e., the non-publication of the names of those whose office it was to judge the various exhibits, which, I believe, was the case with this exhibition. I should like to touch on several other subjects, but fear I have already encroached too much on your valuable space.—I am, yours, &c.,

W. SCORER.

Harant, December 2, 1889.

"BRITISH PHOTOGRAPHIC UNION."

To the Editor.

SIR,—I notice a letter in your last issue from the Secretary of a proposed "National Photographic Union." The proposition therein only extends to the formation of a representative body to watch over the interests of the art and profession; but if the object of the Organizing Council develops into the foundation of a *Trade Union*—that is to say, an organization open to every operative photographer, in any branch, subject to a technical qualification, founded for the support of the workmen in trade disputes—then I claim priority for my proposal in the approaching number of *The British Journal Photographic Almanac*. The copy of my article therein was sent in on November 6, and the proof received and returned in a few days. The subject that I treat of in it has been discussed by me with the well-known trade unionist, Mr. Tom Mann, since last December.

I take this opportunity of asking all who favour the idea of a *boni fide* Trade Union, on similar lines to the Trade Unions in the kingdom, to read my article in *The British Journal Photographic Almanac* for 1890; and also to be so kind as to send me particulars of trade customs, &c., after the manner suggested in the article.—I am, yours, &c.,

Maidstone, December 2, 1889.

ARTHUR G. FIELD.

ELECTRIC LIGHT LANTERNS.

To the Editor.

SIR,—Just a few words in reply to Mr. Lewis Wright to say that, with your permission, I will shortly give the results of certain recent experiments made with both incandescent and arc-light lanterns, which will, I think, quite justify my previous statement as regards the proportionate heat of the two. I trust it will be also sufficient excuse for touching what may be considered the A B C of the subject, because to a number of your readers it is probably an elementary matter, from the fact that few have had facilities for getting the current to use either a powerful incandescent or arc electric light. My experience with arc lights dates back many years, and, in fact, during one of the earliest of the series of South Kensington Exhibitions, I carried out for the late Sir Francis Bolton some experiments with the most powerful electric-light lanterns with a view of projecting pictures on the cascade from the island in the pond from whence the prismatic fountains were worked; so I may fairly claim to know something of the subject, and am in a position to communicate results of trials or modified apparatus that in your opinion may be interesting to the readers of the *JOURNAL*.—I am, yours, &c.,

G. R. BAKER.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—the question 'Amateur versus Professional' is a very simple one—one not at all difficult to solve.

Let the advocates for the claim to monopoly which they give to the professional photographers prove their right to that claim, and then the whole question is settled. The claim must be a just one or an unjust one; it must be an honest one or a dishonest one. It is an old saying that a feather shows which way the wind blows, and writers who advocate this professional claim to monopoly from assumption without proof of their right to it sadly expose themselves. The public will judge them. I shall, therefore, only say that they are unworthy the attention of any man. The professional's right to such a claim is beyond my ken. I have photographed for thirty-nine years and never heard of such a claim till, I may say, recently from correspondence in the journals. Photography owes its existence to amateurs, and to amateurs we look for all future advances. Josiah Wedgwood, Sir Humphry Davy, Niépce de St. Victor, Henry Fox Talbot, and Louis Daguerré, the founders of photography, were amateurs; their labours were given to the world—free to all men. F. Scott Archer was an amateur, and he gave us collodion. Messrs. Kennett, Bennett, and Dr. Maddox were amateurs, and they gave us gelatine—all free.

What, then, have professionals done for photography? And what has photography done for professionals?

I endorse most emphatically every word in that sound good letter from Mr. Wm. Caldwell, of Partick, in your issue of the 22nd.—I am, yours, &c.,

November 30.

F.

To the Editor.

SIR,—Mr. A. F. Jones's letter of last week calls for a reply. He asks "Would it not affect the professional quite as much as the amateur?" Certainly not. To prove this, we must take the difference between an amateur and a professional. The professional of to-day is a man of skill; he knows how to use his brains, and with these his chemicals. On the

other side, the amateur makes a loss. I can count amongst my acquaintances six amateurs, who, were it not for the cheapness of chemicals, would leave it with the expression, "It is too expensive."

During my experience of photography, I have always found the professional to be a man who very seldom made any waste. I had a little talk with an amateur the other day in his own dark room. What do you do with these (indicating a pile of clean glass plates)? Oh, they are spoilt dry plates. How come you to make such a waste? By under and over-exposures. Now, take an all-round professional. Do you think he is troubled with the exposure of plates? Would the public pay what the amateur would be compelled to ask for, sooner than have it properly done at a professional's? Generally, a professional takes two positions; this, compared with the amateur, who gets one good negative out of three exposures, would, in the long run, tell heavily to the advantage of the professional; and sooner than waste the time and money in "studying it by oneself," go straight to the professional's, pay his price, and learn it there and then. We can only stop the "cheap set" man by increasing his costs. This can be done by making him pay for his ignorance. If the chemicals named in my last letter are only minor items of expense, it will greatly help to reach the end desired.—I am, yours, &c.,

23, Cattell-road, Birmingham.

H. VICTOR PAOR.

To the Editor.

SIR,—May I venture to suggest as a remedy the taxation, not of developing agents, but of photographers, both amateur and professional? If a Government license was required, and heavy penalties exacted from those proved to be photographing without a license, two good ends would be served—the Exchequer would be a gainer, and photographers who have legitimate establishments to keep up would secure their much-needed protection.—I am, yours, &c.,

Derby, December 4, 1889.

KAKABEKA.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—I crave a small space in your *JOURNAL* in answer to Mr. Bart Rous's letter in to-day's issue.

There are, I believe, about seventy of Mr. Robinson's pictures shown at the Camera Club. Now as Mr. Rous has chosen to condemn all these photographs as inartistic and untrue to nature, and as he deals only in generalities, will he be good enough to go a little more into detail and point out a few examples in which the "shadows are going in different directions," "combinations impossible," &c., and let us see if he be really a close student of nature?

He must pardon me in saying that when one, unknown to the profession either as a photographer or art critic comes forward and denounces in such a sweeping manner works that have been awarded the highest honours by art-judging committees in nearly all parts of the world, it is not unreasonable that we should wish to know what claim he has to do so. I think, therefore, that he is bound to substantiate the assertion he has made, and let it be seen what the pictures can say for themselves.—I am, yours, &c.,

W. DURRANT.

Torquay, November 30, 1889.

POSITIVES ON CELLULOID.

To the Editor.

SIR,—Referring to your article in to-day's *JOURNAL*, permit us to say that we now supply our sheets finished, polished one side and matt the other, without any increase in price, so that either surface is available, as the photographer's taste or fancy may wish. We think unless very great care were used in cleaning with alcohol or spirit, the finish, either matt or polished, would be destroyed, and in its place the rough unfinished cut celluloid would appear, as in sample enclosed.

We also enclose you samples of our new sheeting, and you will see we are now making it in $\frac{1}{16}$ -inch thick, and upwards by two-hundredths. We also make a sheeting $\frac{1}{32}$ -inch thick, but this we are unable to finish on both sides; either matt or polished one surface can be had, though to cut up it is easiest to score with a knife and bend the reverse way.—We are, yours, &c.,

S. GUITERMAN & Co.

5, Hart-street, Wood-street, London, E.C., November 29, 1889.

Exchange Column.

10x8 oak retouching desk, two and a quarter inch cabinet lens, half-plate box camera want good wide-angle lens.—Address, W., 39, Highgate-hill, N.

Will exchange imitation stone garden seat (reversible), with pillar and vase, for posin chair having three or four backs.—Address, C. E. WEALE, 4, London-road, King's Lynn.

Books on photography (for amateurs) and a few cabinet photographs in exchange for Wormell's *Mechanics* or Ganot's *Physics*.—Address, J. RIGBY, Howick House, Harrogate, Yorkshire.

Will exchange about four hundred BRITISH, AND LIVERPOOL, AND MANCHESTER PHOTOGRAPHIC JOURNALS, dating from January 1, 1857, for a burnisher.—Address, LOU MAX, Photographer, Rotherham.

Will exchange 7½ x 5 bellows camera, six double dark slides, Dallmeyer's triplet lens, and solid leather case, for Ross's or Dallmeyer's cabinet portrait lens.—Address, L. VARNET, Bridge-street, Buckingham.

Will exchange 9 x 7 bellows camera, brass bound, rack and pinion, and three double dark slides with cabinet carriers, for good half-plate bellows camera and dark slides. Address, J. P., Warwick House, Kidderminster.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

J. Owen, Newtown, North Wales.—Three photographs of the Right Rev. Alfred George Edwards, D.D., Lord Bishop of St. Asaph.

M. BARNES.—See reply to "J. Berryman."

J. T. C.—Yes, there is much excellent matter stored away in the old volumes of this JOURNAL.

A. B.—Using the water slightly warm will make no difference; it will not account for the discrepancy.

W. A. WILLS.—Albo-carbon, if properly arranged, is best; next is paraffin with an Argand burner of small diameter.

E. L. W.—Better leave the lens as it is. However, any skilled optical brass worker can remove the bruises from the mount.

OAKLEIGH.—Both forms of limelight are good, but we prefer employing the oxyhydrogen to that in which ether plays a part.

W. E. DOWSON.—There is no reason whatever why the Eastman transferotype paper should not strip properly under the conditions mentioned.

RECTIGRAPH.—There will be no disadvantage in using the larger condenser if the slide be kept sufficiently away from it so as just to be filled to the corners by the cone of light.

CHEMICUS.—Mr. Wellington has, at page 588 of the ALMANAC for next year (published this week), supplemented what he wrote on silver intensification in the last one. To this we refer you.

C. BETTS inquires how the patent scenic backgrounds are prepared.—We do not know of any "patent" in connexion with backgrounds of the kind mentioned. Can a more explicit description or title be given?

A. S.—1. The corresponding lens by the other maker is the No. 3B Cabinet.—2. By purchasing a new lens you ensure the latest improvements, if any, and avoid any risk that pertains, more or less, to second-hand goods.

O. C. J.—No difficulty exists in obtaining permission to photograph anything in the British Museum. Write to the trustees, stating your wishes, which will be readily acceded to. There is a studio there which you may obtain the use of if requisit.

XENO.—We have not seen the work in question, so cannot answer your query. If you will send the book to us, which will be returned at once, or will extract the article, we shall give you every assistance. We strongly suspect you have misread.

R. G. EWINS.—The apparatus mentioned is well worth the money charged for it; but you must not for a moment imagine that it is to be compared with those of the more expensive kinds; nor, indeed, do the makers profess that it is. Still, we repeat, it is good value for the money.

NORTH RIDING.—The "Universal" having a larger angular aperture than the "Symmetrical," is necessarily the quicker acting of the two. There is little, if any, difference between the carte and cabinet lenses specified, and there is no difference between the No. 1 and No. 2 as regards rapidity when worked with full aperture.

LENS (Highbury).—1. The lens you desire is known in the trade as a deep periscopic, and is obtainable from any dealer in optical or spectacle-makers' sundries.—2. Much better employ two such lenses of twelve inches focus each, separating one from the other to the extent of two inches, or a little more or less, as determined by trial.

CORVIST.—Patent plate or British plate glass is useless for a mirror of the very highest class for taking reversed negatives. The glass must have an optically plane surface, which is seldom met with in commercial plate glass. Glass suitable for the purpose has to be ground and polished by an optician with the same accuracy as a lens, and it is more troublesome to do.

PANEL.—Lenses of the "rapid" type are used by many photographers for large direct portraits. Compared with portrait lenses, provided both are worked with their full opening, the former will appear slow; but if the portrait form be stopped down to the same ratio as the full aperture of the rapid—and this many portrait lenses require—their rapidity will be the same.

FERRO-CYPRIC.—The formula is quite explicit. Make a solution of the commercial perchloride of iron which registers the specific gravity given. This you will test with the hydrometer. Commercial perchloride of iron varies in the amount of water it contains, so that its weight cannot be taken as a standard. Use parts by weight. Ordinary *Saxe* or *Rives* paper. Both of these are well-sized papers and require no preparation.

W. S. writes as follows:—"Can you explain the cause of the light and white spots which continually show on my enlargements on bromide paper? You see by the pieces enclosed they render the work perfectly useless."—The spots are caused by air bubbles adhering to the paper during the development. If the paper be thoroughly and evenly wetted with water before the developer is applied the trouble will be avoided.

J. HOLMES asks why cameras are not made of ebonite, instead of wood, because it would be much lighter in weight and less costly.—Cameras have been made in this material, but chiefly in small sizes. But the material is not so well suited for large cameras on account of its brittleness under certain conditions. It is also more difficult to work than wood. If it were utilised we do not expect it would prove any cheaper than wood; and, when damaged, not so readily repaired.

J. BERRYMAN.—We cannot indicate the cause of the spots, seeing that we are not furnished with any details whatever of the method of working, or at what stage of the operation the spots first make their appearance. Such spots may be due to several different causes.

A. Z. A. inquires where the polished opal glass, such as that used some years ago in the demonstration of the "chromotype" process by M. Lambert, is to be obtained, as he says the only opal glass he can get is the matt-surface, such as that used for the pictures one sees in the shop windows.—The glass may be procured from any glass merchant who supplies photographic glass, under the name of "patent plate opal." It is a flashed glass ground and polished on the flashed side.

W. B. WOOD.—If we knew the size of the negative you wished to enlarge we could better aid you. If two condensers, one of them four and the other five inches diameter, will cover the negative, then it is needless waste of light and space to use the nine-inch one, as not only would it be of no good, but it would prove detrimental. But avoid the use of a cast-glass condenser, and procure instead one that is well polished. Better write again and give more details, together with a drawing.

SIGMA writes:—"Since your article on packing dry plates appeared, I put a plate in a dark slide with a piece of newspaper in front of it, but not touching, and after four days' exposure the plate fogged on development; while another plate, out of the same parcel, turned out perfectly clear under similar conditions of development." He says that this proves that much of the deterioration of plates by keeping may be due to the paper in which they are packed.—In the experiment, to be complete, our correspondent should have used a piece of the paper in which the plates were packed. The experiment with newspaper proves nothing, inasmuch as no maker uses newspaper for packing his plates.

J. STONE says, do what he will, his lantern lamp—a four-wick one—gives off most objectionable fumes. He wishes to know if there is any method of preventing it.—If the lamp is properly constructed it should not smell. That is, of course, if it be properly attended to. The chief thing is to see that the combustion is perfect, the flames do not smoke, but appear white and clear all over. The next point is to see that the lamp itself, and the wick tubes, are perfectly clean and dry when the lamp is lit. There is always a tendency of the oil to find its way outside the wick tubes and fittings, and this should always be carefully wiped off before attempting to light the lamp. Most of the objectionable fumes emitted by paraffin lamps proceed from the vapourisation of extraneous oil on the outside. To avoid unpleasant odours scrupulous cleanliness is essential.

PHOTOGRAPHIC CLUB.—Subject for discussion, Wednesday, *Orthochromatics up to Date*.

ERRATUM.—In the letter of Mr. A. Howard Benham in our last, *instead of* "one cubic millimetre square," read "one centimetre square."

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Ordinary Meeting, Tuesday December 10, at 5A, Pall Mall East, at eight p.m., when papers will be read by Mr. W. E. Debenham, *On the Estimation of the Efficacy of Plate Backing*, and by Mr. G. M. Whipple (Superintendent of the Kew Observatory), *Photography applied to Meteorological purposes*.

CAMERA CLUB ANNUAL SOIREE.—A most successful *soirée*, given by the Camera Club, took place at the Suffolk-street Gallery of the Royal Society of British Artists on Wednesday evening. We observed many members from all the leading London societies present. In addition to a few choice photographs arranged on screens, on the walls were displayed the British Artists' Exhibition of paintings; besides which one room was devoted to the phonograph, which sang, played tunes, and recited, to the delight and amusement of the crowds in attendance. In another room a series of short lantern exhibitions was given at frequent intervals. The large gallery contained many specimens of high-class mechanical apparatus, including lathes and tools, together with cameras of the newest and most choice design. The attendance was very large.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—At the meeting held on November 1, 1889, the following memorial was received by the Council of the Birmingham Photographic Society:—"That the Council be requested to call a general meeting (special) to consider the feasibility of a photographic survey of Warwickshire, the object being to secure an accurate and unbiased record of the scenery, monuments, life, natural history facts, &c., of our county as they now exist." This memorial was signed by eighteen members of the Society. In accordance with the rules, the Council have, therefore, resolved to hold a general meeting at their rooms at the Grand Hotel, Colmore-row, Birmingham, on Wednesday, December 11, at half-past seven p.m., to consider the question. The President of the Society, Mr. J. B. Stone, J.P., F.G.S., F.L.S., will preside, and Mr. W. Jerome Harrison, F.G.S., will read a paper introducing the subject, which will then be open for discussion. It is hoped that the other photographic and scientific societies in the county will render their assistance in the work, and they have been invited to send representatives to the meeting.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1545. VOL. XXXVI.—DECEMBER 13, 1889.

FLASHING COMPOUNDS.

COMPOUNDS which burn with the extreme of rapidity, and emit a light of dazzling intensity, are in season at present, when the light of day is all too short, and is withal of too murky a nature to permit of photography being practised with any overweening degree of success between the rising and the setting of the sun. This is emphatically the season for the employment of flashing compounds for evening or nocturnal photography.

To avoid misconception at starting, we will state that the flashing mixtures now to be spoken of do not trench upon the prerogative of the innumerable magnesium powder lamps now so well known, that is, those in which the light is produced by a small quantity of powdered magnesium projected into or through a flame either by a puff of air from a reservoir, a pneumatic ball, or the lungs, or by centrifugal force, but they belong rather to that class to one of which the suggestive name of *blitz-pulver* (lightning powder) has been given by McCollin of Philadelphia.

The characteristic of flash powder is that it contains within itself the elements by which the flash is produced and maintained, magnesium powder being mixed with them on account of its actinic luminousness when ignited under such circumstances.

Methods of producing quick flashing powders had long previously been known, but it was only in 1865 that Mr. Hadow, of King's College, suggested the admixture of a little magnesium powder with one of these, and the present writer believes that he was the first to apply this flash powder to the actual taking of photographs of objects in motion by its agency. In addition to an article published in the spring of 1865, and referred to later on, we read, on page 587 of THE BRITISH JOURNAL OF PHOTOGRAPHY for November 17 of that year, that he, at a meeting of the South London Photographic Society, "ignited a sample of some powder which had been employed by him in the production of photographs at night with an exposure nearly instantaneous. It was composed of sulphide of antimony, chlorate of potash, sulphur, and magnesium filings." Among the photographic feats recorded as having been secured by this powerful flash light were the photographing of an engraving when it was in a state of motion, the obtaining of groups of children at play, and subjects of a like nature taken long after sunset. But this powder was then introduced long before the times were ready for it, but those who have access to our volume of the year mentioned, together with the two succeeding ones, will find that *Photography by a Flash*—as an editorial article in one of them was entitled—was even in those remote times

un fait accompli. The subject lay dormant until two German chemists about three years ago obtained a patent for it, which in the light of what we had previously published was untenable, but which gave an impetus to the introduction of the now well-established modes of instantaneous flashes.

Flash powders of the class we are now speaking of require only the impact of a flame to cause their instantaneous ignition. One of the handiest means of igniting them is that adopted in the lamp devised by Mr. T. H. McCollin for use with his blitz-pulver. The body is composed of a metallic tube filled with cotton wool, which, after being saturated with methylated spirit, is securely corked at one end, the other end being soldered up. Arising from this tube near one end is a wick holder, the wick being buried among the saturated cotton wool. A blowpipe is soldered on the upper side of the tubular body, the height of its nozzle being such as, when the spirit lamp is lighted, to deflect the flame down upon a small platform in front, upon which a charge of the blitz-pulver is placed. The blowing is effected by a rubber pneumatic ball, a flexible tube from which is sprung over the end of the blowpipe. This lamp, when used with the powder mentioned, works with great convenience and emits a most dazzling light.

Without hazarding any opinion as to the precise constitution of the American blitz-pulver, it may be interesting to give here an extract from an article we wrote for the number of this JOURNAL for May 26, 1865, page 274. "During the past few weeks it has been discovered that magnesium possesses some peculiarities which were not supposed previously to reside in it—for instance, that by mixing it with some other substances it may be imbued with explosive properties of enormous power. Within the past week we have been trying experiments with a view to ascertain the capabilities of some of these magnesium compounds for taking instantaneous pictures at night. The duration of this new magnesium flash is extremely short, occupying only a mere fractional part of a second; but its actinic power is so great that we have been enabled to produce in the camera a negative of moderate intensity." Then follows the formula suggested to us by Mr. Hadow, the Demonstrator of Chemistry in King's College, which was approximately as follows:—

Chlorate of potash	4 parts.
Sulphido of antimony	2 "
Sulphur.....	1 part.
Magnesium (in powder)	1 "

This was followed by a caution, which we here strongly emphasise: See that each article is powdered *before mixing together*; then mix carefully with a bone or wooden spatula, as the mixing of them in a mortar by means of a pestle will be

attended with danger. The proportions above given may be departed from, or changes may be made in its nature.

There are several substances which we may here mention as capable of being used in compounding a flash powder, and in these we shall omit the magnesium, leaving each experimentalist to add as much, or as little, of this necessary ingredient as he finds to fulfil his purpose in the best manner.

No. 1.	Chlorate of potash	1 part.
	Ferrocyanide of potassium	1 „
No. 2.	Chlorate of potash	2 parts.
	Sulphuret of arsenic	1 part.
No. 3.	Chlorate of potash	5 parts.
	Sulphuret of arsenic	2 „
	Ferrocyanide of potassium	1 part.
No. 4.	Chlorate of potash	9 parts.
	Sulphur	$\frac{1}{4}$ part.
	Wood charcoal	$\frac{1}{4}$ „
No. 5.	Chlorate of potash	2 parts.
	Sugar	1 part.
	Ferrocyanide of potassium	1 „

We might increase this list to an indefinite number; but from the formulæ given a fair idea of the nature of the additions and their quantities will be perceived. Each of these formulæ forms in itself an explosive mixture possessing great force, and is here given as the medium to which a large admixture of magnesium is to be made. With such an addition they go off very suddenly, and are attended with a light of great intensity. A burning match, the impact of the flame from a spirit lamp, nay, in almost all of them, a drop of sulphuric acid falling upon the powder will cause its instantaneous ignition.

SULPHUROUS ACID IN THE FIXING BATH.

UNDER the title of "The Acid Fixing Bath," several references have been made recently in the foreign journals to a combination of sodium hyposulphite with sodium bisulphite, or sulphite and an acid, for the purpose of fixing and clearing gelatine negatives in one operation. The idea of an acid fixing bath is, in the first place, especially to an "old hand," in the utmost degree heterodox, as it is well-known that acids—most acids, at least—decompose the hypo with precipitation of sulphur and other noxious compounds. Upon looking more deeply into the matter, however, there is more reason in the suggestion than would appear at first sight.

It has often been remarked how slow photographers are to adopt new ideas or suggestions, and such is the case in this instance. As far back as 1885, in a leading article published in our issue of June 5th, we described a new clearing solution for gelatine negatives and bromide prints, consisting of alum in conjunction with sulphurous, in place of citric or hydrochloric acid, as ordinarily used. A variety of methods for the preparation of the bath were described, but preference was given to the addition to the saturated solution of alum of a quantity of sulphite or bisulphite of soda. If the latter be used, the necessary conditions—free sulphurous acid—are fulfilled; and until the free acid is exhausted, the compound solution possesses strong decolourising properties. If the neutral sulphite be employed, it will be necessary to add a certain quantity of almost any acid to liberate the sulphurous, and this is, perhaps, the best plan, since by adding, in the first place, an excess of

sulphite, it may be decomposed, little by little, by successive additions of acid as its decolourising properties are exhausted, and in this manner the volatile sulphurous anhydride is economised and the nuisance of its pungent fumes prevented.

The special advantages we claimed for this bath were not only greater clearing powers, owing to the powerful bleaching action of sulphurous acid, but also that owing to the latter exerting no decomposing action on the hypo much less washing was required between clearing and fixing than is the case when citric or hydrochloric acid is employed. This is often, especially in hot weather, a matter of some importance. In view of the harmlessness of the mixture of hypo and sulphurous acid, we carried the matter still further by dispensing altogether with the alum bath and making the fixing solution perform the double function, but though we spoke of the matter to several friends at the time, we made no public mention of the novelty pending a thorough test of its reliability, which was doubted by some. Now that it has been revised, we can speak positively in favour of the innovation when suitable precautions are taken.

Some two years and a half subsequent to the article referred to, in December, 1887, Mr. Herbert B. Berkeley took out letters patent for an improved method and process for fixing negatives, consisting practically, though we forget the exact details, of a combination of sodium hyposulphite with free sulphurous acid, or its equivalent. But as Mr. Berkeley himself explained a few weeks ago, owing to protracted ill-health he has been since unable to push the matter. So much for the earlier work in connexion with the acid fixing bath.

Since the more recent revival of the idea on the Continent, we have been carefully testing the acid bath in its various forms, or, rather, comparing the different modes of preparing it, and now propose to give our experience, premising that our experiments have been rather directed towards the readiest method of preparation rather than to efficiency, of which the demonstration was not necessary.

Perhaps the simplest, as well as the best, method of procedure, when it is possible, is to add directly to the hypo solution of ordinary fixing strength a sufficient quantity of the solution of sulphurous acid obtainable commercially. This plan saves all chemical calculation, and is perfectly safe in every way, as the pure sulphurous acid has absolutely no decomposing action on hypo. But, unfortunately, sulphurous acid is not generally or readily obtainable, except in large towns, and even there the purchaser has very little guarantee of its quality. It may be weak from evaporation, more probably it is partially oxidised, and, in consequence, represents little more than an addition of very dilute sulphuric acid. On grounds of prudence and convenience, then, we can scarcely recommend the direct method.

A modification in the use of sulphurous acid pure and simple, which has the disadvantage, however, of being a little troublesome to those who are not possessed of chemical apparatus or well versed in its employment, consists in forming the gas by double decomposition and passing it into the hypo solution, where it is absorbed or dissolved. For this purpose it is necessary to provide a bottle with a perforated cork, through which is passed a bent glass tube, which should only reach a short distance through the cork in the interior side, but be long enough on the exterior side to dip into another vessel containing the hypo solution. In the bottle to which the cork is fitted is placed a solution of sulphite, bisulphite, or hyposulphite of soda—the latter being quite distinct from the

fixing solution it is intended to charge with SO_2 —and all being ready, a suitable quantity of citric or tartaric acid in crystals is thrown into the generating bottle, the cork firmly inserted, and the outlet end of the tube plunged into the vessel containing the hypo solution. As the crystals of acid dissolve, they decompose the salt already in solution, liberating sulphurous anhydride, which, passing over by the bent tube, is absorbed by the fixing solution in the other vessel. As regards quantities, the proportion of sulphite of soda used may be about one-eighth of that of the hypo in the bath to be charged; or, if bisulphite or hypo be used instead, about one-half that proportion. The quantity of acid must be sufficient to decompose the whole of the sulphite used.

The simplest of the "indirect" methods consists in the addition of any acid—preferably, however, hydrochloric—to the hypo solution itself, and allowing time for the precipitated sulphur to subside, the solution being meanwhile kept carefully corked to prevent loss of the SO_2 . This plan is, however, objectionable on the ground of the length of time required for the fine deposit of sulphur to subside.

Better is the method of decomposing either the neutral or bisulphite with hydrochloric acid, leaving, however, an excess of the salt, and adding the solution thus formed to the fixing bath. The decomposition must be complete before mixing the two solutions, otherwise any free hydrochloric acid will act upon the hypo and throw down sulphur on the bath itself. This is only objectionable on the score already mentioned of the length of time required to free the solution of the precipitate.

If this plan is followed, the quantities of sulphite or bisulphite employed may be the same as those already named—one-eighth or one-sixteenth respectively of the quantity of hypo; but the acid must be so proportioned as to leave a trace of unconverted salt.

The weak point of all these methods, however, lies in this: If a sufficiency of free sulphurous acid be formed at first to produce a useful clearing effect, it rapidly escapes by evaporation, and the bath becomes a simple fixing solution. We, therefore, prefer to keep the concentrated sulphite and acid solution separate, and to add it in small quantities to the fixing bath as the latter shows signs of losing its clearing power. Indeed, for some reasons, it is preferable to keep even the sulphite and acid separate, and to mix definite quantities of each just before adding to the hypo. The only precaution to be observed is to have always an excess of sulphite, otherwise there will be sulphur precipitated.

Observe that on no account must the decomposition of the sulphite be allowed to proceed in the presence of the hypo, that is to say, in the fixing bath itself, or there will inevitably be precipitation of sulphur.

With the precautions indicated the acid fixing bath may be used with perfect safety, and with the decided advantage of saving the separate operation of clearing either gelatine negatives or developed prints.

PHOTOGRAPHING INTERIORS.

No. III.

APPARATUS chosen, and its mechanical utilisation arranged for, it is permissible to retrace our steps and return to the more obvious order of things and dwell upon choice or arrangement of subject, consideration of which, for the reasons explained, we

deferred. Every one with much experience of the subject is aware, and those who have none will very quickly learn, that the greatest difficulties to be encountered arise from windows and open doorways, and some of them cannot be successfully encountered save by a method of evasion.

The camera is placed in a suitable position, everything looks well on the ground glass, exposure and development follow, and all looks right except the window. The sash bars have vanished; nothing is to be seen of the view. Beyond all this, all round the window—above, below, and at the sides—there is a more or less wide fringe of fog, the well-known "halation." This effect embraces far more than has yet been written about it; but for the present, working on known lines, it may be explained as being caused by the brilliant light of the image thrown upon the film passing through in part at all angles, and being reflected at the back of the plate upwards to the film again, and a portion also possibly being spread laterally by reflection within the texture of the film. The effect is to cause so much light action upon parts of the image comparatively slightly illuminated that their feeble impressions are merged entirely in this flood of reflection. As to the means of cure, they are nearer to or farther from perfection, according to the intensity of the outer light and the extent to which it is allowed to pass through the window or other opening. As regards the plate itself, a brand should be chosen which is rich in silver—a thickly coated plate, which reduces the amount of light that can possibly pass through. Next, all plates intended for use in interiors should be "backed" with a non-actinic pigment held to the glass by a medium of somewhat similar refractive power, such as gum, &c., or an opaque liquid as asphaltum varnish applied, or one actinically opaque, as collodion tinted with aurine and magenta. This treatment will minimise the evil. There are, however, other expedients sometimes far more efficacious partaking of the nature of evasions.

It will often happen that the window that causes most trouble is not the main source of the light in the room, and in that case the photographer should before exposing carefully draw the curtains, so as perfectly to cover the window and hide the outer view entirely, and then uncapp the lens. When sufficient exposure has been given, the lens should be carefully, and with a light hand, covered again, the curtains then removed from the window, put in their proper position, and, finally, the lens uncapped again for a brief period. It will be found that the folds of the curtains will receive sufficient light from the open window in their last position to be sufficiently indicated, and if not of very dark material, the impression of their folds, or their pattern when spread over the window and illuminated from other windows, will be entirely eradicated by the new and strongly illuminated image of the view seen beyond. One of the prettiest interiors we ever saw was treated this way. An old timbered room with polished oak floor opened into a spacious hall, again of polished oak, and at the farthest visible point there opened out a door showing a delightful peep of country and a brilliantly lighted, cloudy sky. An hour's exposure for the timbered apartment would have meant, under any conditions of plate-backing, a foggy, muddy doorway if the door were left open, and the picture losing more than half its charm if the view were hidden by keeping the door closed; but the photographer who took the view knew his business. He shut the door and exposed the plate for an hour, then, capping the lens, threw the door open again, and re-exposed for a couple of seconds. Even that time was too much to get a clear view of the outside; but a beautiful crisp picture, with an open door

looking out into the open air beyond, and light reflected from the polished floor, was produced by this little expedient.

There will be instances, of course, where such a method of procedure cannot possibly be adopted; the window is there, it cannot be closed or covered, and must be made the best of. But it is sometimes possible even then to evade it; a different point of view may be chosen, and the window hidden by some friendly pillar or other architectural surrounding. If even this be denied the unlucky worker, there is but one mode of amelioration left. He must choose a time of day, or a condition of light, when the sky or view outside is the least brilliant. A south window to be taken morning or evening, a west window early in the day, an east window late, and so on.

We have referred to the method of taking a picture of a room by covering a window with a curtain and allowing the light from other windows to illuminate the apartment and the objects to be photographed. If, however, the window or windows face the observer, and objects to be photographed lie between it and the camera, such a method is obviously out of question. Here, of course, ordinary methods will produce results only of a very unsatisfactory character; but a magnesium flash light can be, and has been, used with great success. We may give a case in point. There has lately been issued, illustrated by photography, a history of the Stevens' Institute of Technology, and one of the views therein depicted is an example of just the difficulty we describe, and which was overcome by magnesium. Facing the camera was a row of windows, with a multitude of dark objects dimly illuminated between camera and window, and yet all is clear and distinct. A negative had been taken first to show where the illumination was deficient when these end windows were covered with screens. Then the windows were again covered over, a long exposure given, pistol flash lights fired to illuminate the spots indicated in the trial negative, and, finally, the lens capped, the window screens removed, and a half-second's exposure given to the view beyond. The result is an excellent harmonious whole, giving detail wherever required, and exhibiting neither fog nor unnatural darkness.

From a parliamentary paper recently issued, which contains a report by the Assistant Secretary of the Marine Department of the Board of Trade, it would appear that colour blindness is on the increase rather than otherwise. Out of 789 persons who were desirous of testing their capacity to distinguish colours, without reference to further efficiency, 4.56 per cent. were rejected. Last year, with the same tests, the rejections were but 3.94 per cent. The failing colours were, as usual, black, red, and green. Thirty-two of the number tested described red as green; six, green as red; sixteen designated green as pink, and seventeen black as red, while no less than fourteen described black as green. Colour blindness, or partial colour blindness, exists to a great extent amongst photographers without their being aware of it. Some we know are quite unable to tone a batch of prints even approximately to the same colour; also that when the discrepancy—which, by the way, is often charged to carelessness—is pointed out they quite fail to realise the fact.

The early arrival of winter has been taken advantage of by many photographers to secure hoar frost and snow pictures. What is somewhat unusual with hoar frosts at this time of the year, they have been, in most districts, accompanied by a fairly good light for photography, so that good results have been obtained. Some of the pictures we know will be used for Christmas and New Year's cards. We were shown some charming frost pictures recently taken which were

printed on opal glass. Good hoar frost pictures on opal are exceedingly effective, and form capital "seasonable greetings."

THE severe weather we have already experienced—and the meteorological conditions show that the winter may be a hard one—has caused discomfort and inconvenience to many photographers in the shape of frozen water supply and burst pipes. Much of this trouble might be avoided if a few timely precautions were taken on the advent of winter. A few thicknesses of felt carpet bound round or fastened over a water pipe will generally prevent its being frozen, even in exposed situations. When a water pipe does get frozen it should at once be examined throughout its length to see if it has burst. If it has, the plumber can be sent for immediately to effect the repair. If the pipe be mended before the thaw sets in all the damage and annoyance usually accompanying a burst pipe will be averted. And what is more, while the frost lasts there is no difficulty in obtaining the services of a plumber at short notice, which is not always the case after the thaw commences, as many know to their cost. The once popular notion that the frozen pipe bursts with the thaw is not likely to be indulged in by many of our readers, as the majority of them are fully aware it is the expansion of the water in the act of freezing that produces the fracture. The effect, however, is not manifest, unless sought for, until the water regains its liquid condition.

PIPES seldom freeze during the daytime, where the water is in constant use, as the movement prevents its congealing. It is only when at rest that the trouble arises. If the tap be left slightly running the water will rarely get frozen. But this means a considerable waste which cannot always be afforded. In this case the best way of preventing the pipes freezing is to empty them every evening after the work of the day is finished. This is easily done by plugging the exit pipe at the cistern with a piece of tube—say "iron gas barrel"—long enough to reach a little above the level of the water. The end of the tube may easily be made to fit by winding round it some linen rag. When the pipe is plugged all the taps should be left open. By this means the pipes will be completely emptied, so that there is nothing to freeze. In the morning the tube is removed and the supply restored as usual. The reason for the hollow plug is, that if a solid one were used there would be no vent at the top; hence, although the taps might be opened, the pipes would still remain full. Frequently the service pipe from the main is laid so near the surface of the ground that it gets frozen. This inconvenience may generally be avoided by placing over it some more earth, or, better still, a good thickness of stable manure. This is an admirable material for covering exposed pipes during frosty weather.

IN a watchmaker's window we recently noticed a number of photographs of well-known London buildings in which the clock face had been cut out and an enamelled dial inserted in its place; in fact, a veritable timepiece was introduced in the photograph. There is no novelty in this, as real clocks in paintings are of very old date, and we saw some in photographs a few years ago. Those were silver prints, and at the same time we saw them they were showing signs of fading. We had no opportunity of judging by what process those recently seen were produced, but they had all the appearance of being silver prints, and were very indifferently coloured—yellow preponderating. If they are silver prints it will be interesting to see how they will look a few years hence. A faded and yellow photograph with a brilliantly white dial to show the time will not be a very ornamental clock.

Do photographers, as a rule, take sufficient care of their lenses? Many professional portraitists pay high prices to secure the most perfect instruments, but do they take even ordinary care to retain this perfection? The answer, in the majority of cases, must be in the negative. In many studios the lenses may be seen standing about with the glasses full exposed to light, atmosphere, and dust. When the instruments are required for use, the accumulated dust is generally wiped off with the first thing that comes to hand—say the pocket handkerchief, or, more frequently, the focussing cloth, which is often as well charged with

dust as the lens itself; hence the continual friction with the dust particles destroys the high polish of the glass, which the optician has been at such pains to obtain. We recently saw a costly portrait combination that had been many years in use in which the outer surface of the front lens, through constant careless wiping, had become quite dull and grey—about the condition that an optician would describe as semi-polished—while the inner surface retained its original polish. The contrast was great. This abrasion of the surface of a lens of course means a loss of light; but that is not all, the brilliancy or crispness of the image is also considerably impaired. Purchasers of second-hand lenses should bear this fact in mind.

WHEN a lens is accidentally dropped, if none of the glasses are broken, although the brasswork may be considerably dented, it is often thought that no actual harm has been done to the instrument. This is frequently a great mistake, as the bending of the brass may so jam or cause unequal pressure on the glass as to alter the figure of the lens and so reduce what, at one time, was a very perfect instrument to one of mediocre quality. By careless usage a lens by the best makers may ultimately be so reduced in quality that its performance is no better than one costing but half its price, or even less.

WHILE the subject of amateur and professional photography, and how the former is likely to affect the latter as a business, is once more to the fore, the following conversation recently overheard at an evening party, when some proofs of a portrait were under criticism, may be interesting:—"What enormous profits those photographers make! Charley has got a machine for taking photographs, and he told me the glasses only cost a penny each, and the papers for the pictures but a few pence a dozen. 'The things are nearly all profit.'"

SENSITOMETRY IN TWO CHAPTERS.

CHAPTER I.

THE measurement of the so-called actinic force of light and of the sensitiveness of photographic surfaces are so intimately connected that the terms "actinometry" and "sensitometry" in some senses appear almost synonymous or pass as such, though in reality they are opposite applications of the same principle. The one signifies the measurement of the chemical force of light by means of a sensitive surface of known value, the other the estimation of the sensitiveness of any given surface or preparation by exposure to a standard light under suitable conditions. Such at least is the theoretical significance of the terms, but how imperfectly the two processes are carried out in practice is only recognised by those who have carefully studied the subject, or who have endeavoured in however small a way to arrive at definite and intelligible conclusions in either direction.

The science of "photometry" as distinguished from actinometry, has been brought to a comparatively high degree of perfection of late years, and it is not difficult to arrive at closely accurate estimates of the illuminating power of lights of widely different values; but here the conditions are infinitely more simple. In comparing the relative values of two simple illuminants we have something tangible to work upon, or at least the issue is kept within a restricted area. Yet here the great existing difficulty is the want of a "standard" light by which to make the comparisons. But when we turn to actinometry, we are met by the necessity, not only of a standard light, but of one that shall be equally available for use with daylight, electric, and other artificial forms of illumination, differing vastly, not only in power, but also in character, but which shall also do duty in connexion with substances varying fully as much in general sensitiveness, and to rays of different colour and refrangibility.

In photometry, for instance, given a reliable standard of comparison, it is easy to state the value of any form of illumination in terms of so many standard units—so many "candle power" in general practice, the visual power of the two lights being compared with something like mathematical accuracy by well-known rules. But in actinometry the standard which would be reliable for one kind of light would possess little utility in connexion with one differing altogether in the rays composing it. It is equally difficult, too, to apply the same

standard to daylight, electric light, or magnesium, which are rich in rays of high refrangibility, and to gas, lamp, or candle light, in which the luminous and heat rays present the largest proportion. The impossibility further of comparing in a satisfactory manner, by means of the same standard, substances differing no more than the various haloids of silver do in their selective sensitiveness to different portions of the spectrum or so widely removed in general as well as selective sensitiveness as a rapid gelatine plate and, say, a sheet of carbon tissue, is manifest, and clearly place actinometry and sensitometry in a distinct category from photometry.

Even if we confine ourselves to the measurement or comparison of one kind of light—as, for instance, daylight at different times—or of one kind of surface—as gelatine plates of varying makes—we are met by the same kind of difficulties in only less degree. Thus, to take two instruments well known to photographers, the Warnerke actinometer and sensitometer, the former proves utterly reliable in comparing the value of bright summer sunshine at mid-day and the differently constituted light of winter or of evening. The sensitometer, too, is known to give utterly false readings of the comparative sensitiveness in the camera of films whose chemical composition is different, owing to the vast difference in selective sensitiveness between the phosphorescent tablet and daylight of ordinary quality. For the feebleness of artificial light in the one case, and the less sensitive forms of photographic surfaces in the other, both instruments are utterly useless. Still further instances may be brought forward, such as the "photometers" in ordinary use by carbon printers, and similar instruments constructed on the same principle for the estimation of camera exposures. In any of these the sensitive material employed in the instrument differing from that in the printing frame or camera can at the best of times only give an approximately accurate result, and this will vary from time to time with the time of day, period of the year, or, in fact, as the composition of the light favours more or less one or other of the sensitive materials.

It is difficult in the present state of our knowledge, and with existing facilities, to imagine the possibility of satisfying these conflicting conditions to the extent of establishing a "unit of light" for photographic purposes, if even no greater reliability than the standard candle. The importance of the question is beyond all doubt, and its very difficulties are the best explanation of the reason it has been so long apparently neglected. I say "apparently" neglected, because in reality innumerable attempts have been made by individuals and societies, and in every period of the history of photography, to cut the Gordian knot, but without success. The very vastness of the subject, the fresh ramifications it presents, the more deeply it is studied, and, above all, the great amount of close and persistent work it involves, place it altogether beyond the scope of individuals or committees whose labours are merely those of love.

It will be remembered that some eight or nine years ago the Photographic Society of Great Britain appointed a committee to investigate the matter, but the net result of their labours can scarcely be said to have advanced matters much, as they were only able to recommend the Warnerke sensitometer as the best compromise for a standard. It is not to be denied that this has proved eminently useful in many respects, and has established an approximate means of comparing, under certain necessary conditions, the relative sensitiveness of *gelatine films*; but it does not even enable us to settle the vexed question of the comparative sensitiveness of collodion and gelatine; for actual camera purposes it is useless in comparing even plain bromide and bromo-iodide plates, while for anything of a lower degree of sensibility it is utterly out of court. It can, therefore, never be accepted as a universal or international standard.

The subject was again revived at the French Congress held a few months back in Paris, but all that is definitely known, so far as the reports that have reached us are concerned, is that the question is still open for discussion at next year's Congress to be held at Brussels. There is, therefore, some hope that, though no immediate result has yet accrued from the past discussion, some ultimate benefit may be gained.

The promoters of the Congress apparently recognised the full importance of the want of a uniform standard of light by making that the first subject of discussion; but whether it is necessary that the photometric and actinometric units should correspond is open to

doubt. What practical utility there can be in "comparing spectrophotometrically with special reference to the rays in the neighbourhood of 'G' in the blue of the spectrum," a standard of luminosity with another where not luminosity but chemical action is the point, it is difficult to see. What is really required is a standard consisting of a luminous source, corresponding in its character and composition as closely as possible with sunlight, that is to say, giving a spectrum as nearly like the solar spectrum as possible. If the Violle standard or the acetate of amyl light answers these conditions, well and good; they may then be at once of some use photographically, and at the same time bring photometric and actinometric estimations within comparable distance in definite terms. It matters not how much the accepted standard may vary from solar light in absolute intensity, so long as the proportions of the visual and chemical rays in each are in tolerably close correspondence; but, failing that, no advance is made.

If, for instance, the accepted standard—be it the "Violle," the pentane, or the amyl acetate—be poorer in the rays in the neighbourhood of "G," or, what is the same thing, be richer proportionately in those about "D," than sunlight, it will be impossible to estimate in definite terms the relative degrees of practical sensitiveness of gelatino-bromide plates and, say, ordinary sensitive albumenised paper, or even of plain bromide plates and those containing iodide or chloride. The surface richer in bromide would, under such circumstances, be made proportionately more sensitive than it should be, owing to its greater sensitiveness to the rays of lower refrangibility. If, however, the relative proportions of the luminous and active rays of the standard be approximately the same as those of sunlight, it will be possible to say that a gelatino-bromide, bromo-iodide, or bromo-chloride plate is x times as rapid as albumen-chloride or platinotype paper, and in actual use the figures will closely agree.

This would, of course, necessitate the establishment of an arbitrary standard of solar light, since this varies so materially from day to day and hour to hour, and with this the artificial unit would have to be brought into co-relation. In thus fixing and comparing the natural and artificial standards or units, a standard sensitive surface would be required, and this the Congress appears to have at least partly overlooked, so far, at any rate, as concerns the new difficulties it introduces. I imagine, however, the sensitive material selected should be that which has the greatest general sensibility, or, in other words, which is acted upon by the largest number of rays of the spectrum. So far as I know, plain bromide of silver fulfils this condition; but how it is to be prepared of a uniform and invariable degree of sensitiveness forms, perhaps, one of the greatest difficulties to be encountered.

With regard to the further complications alluded to in the Congress report, as introduced by variations in development, these of course form another phase of the question requiring full discussion and investigation by a competent tribunal, and I only mention them here, in connexion with the other theoretical difficulties, in order to emphasise what I have already said as to the vastness of the subject.

The mechanical side of the question is, of course, simpler; but I should like to point out that even this is not perfectly plain sailing.

W. B. BOLTON.

THE IMPROVEMENT OF FAULTY NEGATIVES.

No. III.

HAVING in my previous articles instanced a few cases of negatives faulty in respect of posing and lighting, I now proceed to refer to some other instances in which much may be done in the way of improvement also. A by no means uncommon fault to be met with in the case of some portrait negatives is that of the catch light on the eye not being similar in both. Here a clever modeller can work wonders with a sharp needle and magnifying glass. A few judicious touches on the negatives will easily remove parts of the catch light on the faulty eye; after which, should any further modelling be needed, the negative can be varnished and touched up with pencil.

But it is not only in cases of portrait negatives that faults of opacity have to be remedied. Quite as wide a field for improvement will be found in the cases of landscape, seascape, &c.; in fact, there is no limit to the numerous instances where improvement may be effected. As I write, I have a typical case before me. The negative in question is that of a steamer going at full speed; the paddles are

churning up and leaving in her wake large masses of white foam; in this instance, through faulty development, the negative prints too hard in some parts, and no matter how careful the printer may be when printing same, by dodging up and shielding, it is almost impossible to get any softness in these opaque parts. In this case, the exposure being a rapid one, the fault lies clearly at the door of development, too much pyro having been used in bringing out the image, and also the other ingredients being over-strong. The negative shows too violent contrasts and lacks middle tint—this is a very common mistake with beginners. I find, over and over again, the idea prevails that those who have but little experience in developing such subjects as have strong contrasts, that the proper course for them to follow is to mix a developer strong in pyro, the idea evidently being that because the plate has received but a short exposure it must necessarily be forced up in development. In one sense, doubtless, this is right enough, but in such cases as I am considering such a treatment is quite wrong, and must be fatal to success. A golden rule to follow in development is, where violent contrasts exist reduce the pyro, and when but little contrasts are in the picture, such as in cases of open landscape, be liberal with the same and develop slowly, thereby in the latter cases obtaining as much vigour and contrast as possible. In the former case, however, the aim should be to avoid over-contrast, and this is best secured by a minimum quantity of pyro and sufficient accelerator as to bring out the details in the shadow parts before the high lights become over-dense. So much for prevention, which at all times is better than cure; but when the best is to be made out of an error, then I have no hesitation in saying go ahead and make a new negative by means of a transparency in which some toning down of the high lights are worked in by means of a thin wash of Chinese white or other suitable means. Such a case as I have instanced is very frequently met with, also in pictures of camp life; here the high lights are very frequently over-developed before the dark clothing of, say, a group, or it may be other surroundings, are brought out. So much for cases of faulty lighting, posing, and development.

Now let me refer to a few instances often met with through the employment of faulty apparatus. Who is there, I wonder, who in the course of his working has not met with numerous instances of annoying flaws in their negatives caused by leaky slides? And perhaps one of the most common troubles coming under this category is that where a slide, through the fault of such vile material as Yankee cloth being used in the making of the hinges, causes, after a short time of using, a fog line right across the negative, or, it may be, only partially so. I have during the late season had numerous cases of this kind brought before my notice. Here, doubtless, it will be found that the opacity penetrates deep down into the film; in fact, so much so, as to prevent the trouble being removed with a scalpel, for no matter how expert a modeller may be with a knife, when such flaws enter deep into the film it gets quite beyond his power to deal with it without a great risk of causing what is perhaps as great a trouble in another direction. I know quite well there are cases where much may be done with a knife towards the removal of flaws, but as a rule, in my opinion, such a remedy is only allowable where the fault lies on the surface of the negative. I may, just at this juncture, instance a case where such a treatment will be found to answer. It frequently happens, in the cases of some double backs, that after a time their velvets become worn, and when such are used in broad daylight they are very prone to cause surface fog just at the corners or edges of the plate. As a rule, such flashes of light do not enter deep into the film, and therefore a scalpel judiciously applied will easily remove, or, at least, considerably improve negatives faulty in this respect. Of course, much will depend on the class of subject whether or not the use of a knife be permissible. When such, however, will be found to interfere with any fine detail, it is better to avoid using it altogether and fall back on the other mode of treatment I have recommended. In cases, however, such as an ordinary seascape or landscape, where the foreground contains nothing of great importance, it is a very useful tool to employ, and often saves the necessity of the more roundabout way of making and working up a transparency.

Another class of subjects frequently met with where a considerable amount of improvement may be effected is that of groups taken in sunshine. Here it frequently happens that the high lights run too abruptly into the shadows, and no matter how carefully a modeller may work upon the edges of the high lights, so as to blend them somewhat into the shadows, the result is not always as good as could be desired. When such, however, is treated by lowering the tone of the high lights in the positive, in conjunction with as much work as is possible on the original negative, it is wonderful what an amount of improvement can be effected. Groups are, of course, best taken in a good diffused light; but where is the operator who can at all

times choose such places or obtain such circumstances as yield him the opportunity of taking them under the best conditions?

Having considered some of the many cases of faulty negatives arising out of over-opacity, I now proceed to refer to a few cases of a somewhat different type. And, first of all, perhaps there is no larger class than that of landscape negatives faulty in pluck and vigour. Since the introduction of the extra rapid series of plates very frequent trouble arises in the way of poor, thin results, and in no respect is this more noticeable than in the class of prints such plates yield. My idea of the printing quality of a negative has all along been that when such possesses the pluck and vigour which enables the shadows to become bronzed over when the high lights show a slight reduction, we have one that will yield at least fair results in printing on the ordinary albumenised paper of commerce. But, alas! how difficult it is with a very large proportion of amateurs, or professionals either for that matter, to obtain such a class of negatives with the fast, runaway plates of latter days! In place of turning out such negatives, as a rule we meet with poor, thin images, ghosts in fact, and it is enough to make one sick of trying to get anything like decent prints from same. In cases of this kind, where the sky is too thin, much may be done by working in, on the glass side, some imitations of clouds with a sable brush and Chinese white. A novice attempting this for the first time is almost certain to overdo it; that is, it is just about ten to one he will lay the colour on too thick, and therefore produce a ludicrous result in the print. What is wanted in such cases is not an actually well-defined cloud effect, but rather the securing of atmosphere. A very slight wash of the colour, applied in varied forms resembling wavelets of small dimensions, will be found to improve matters, and when such negatives are vignettised in printing, matters will be further improved.

So much for the sky. There are other portions also, such as the foreground, which can be considerably improved by working up with Chinese white or a pencil, only when doing this it is best, in fact imperative, that the modelling be done on the face of the negative, otherwise crispness would be sacrificed. Ground-glass varnish comes in also very handy, and when applied on the glass side of the negative permits of much being done in the way of procuring a little pluck. In applying this varnish, when it is desired to add density to any part of the negative it is best to flood the entire surface of the glass side, and when set, placing the negative on a retouching desk; the varnish can be scraped off from such parts as it is deemed expedient to remove it from. Too heavy shadows can also be improved by the application of this varnish, in which case the varnish should be removed from the surface of the more opaque or denser parts of the negative. Much may be done with this most useful adjunct to the printing room, and when used in conjunction with brains, and a slight modicum of wash colour, it is wonderful in how many ways improvements are effected with it. Mineral paper is also a most useful material, and in many ways serves the same purpose as ground-glass varnish; and where stumping has to be done is of the two, perhaps, the most preferable. Let some of my readers should not be aware of the best means of applying this useful material to the face of a negative, I may just say that the *modus operandi* is as follows:—

A piece of the paper is taken and cut to almost the size of the negative (just a trifle smaller, say about a sixteenth of an inch, however, is the best). This is placed in a dish of clean water for a minute or so, taken out and placed between sheets of clean blotting paper: the face of the negative (glass side) being quite clean and free from spots or specks, a camel-hair brush is dipped in gum, and a small edging of same is run round the negative; the mineral paper will now be nicely damp and limp, and is placed over the glass side of the negative and made fast by the gummed edges; it is then set up on end to dry, and in a very short time it will be found drum-tight, and giving a most excellent surface to work on with pencil or stump, or, if desired, portions may be cut out with the blade of a sharp knife. As a rule, the edges of the paper round the portions that have been removed will curl somewhat, and this is just what is required, for it prevents hard and fast lines appearing at those portions in the print where it was cut out on the face of the negative. When deciding to employ this means of improving parts of a negative, it is necessary to cut somewhat slightly inside the limits of the flaws, because the slight curling acts somewhat as a vignetter and blends the edges nicely.

In my next I hope to refer to the treatment of accidental flaws, such as cracked negatives, &c. T. N. ARMSTRONG.

SIMULTANEOUS EXPOSURE AND DEVELOPMENT OF ENLARGEMENTS.

It would be interesting to learn more fully the particulars of the method and formula used by Mr. A. Maskell for developing bromide enlargements with hydroquinone during exposure. Photographic

literature on that subject is very scanty. Indeed, with the exception of your brief report of the proceedings of the Camera Club in your issue of November 29, and my own short contribution to the *International Annual* (vol. ii., page 405), I have not observed anything written on the subject; on that account I am led to append a few jottings from my note-book which may prove of interest to those who wish to amuse themselves making enlargements during the long winter nights.

Carbonate of potash or soda is preferable in the developer to the hydrate of either, because the latter is gradually converted into a carbonate during a long exposure. It is better, therefore, to commence operations with the more stable substance. The caustic alkalies render some makes of gelatino-bromide very sloppy.

The best results are not obtained by simply floating the paper on the ordinary developer and then exposing. A very flat and feeble picture is most likely to be the result, because the paper did not contain enough of the developer to give a vigorous image. If a correctly exposed gelatino-bromide negative be soaked in a developing solution until the film is thoroughly permeated and the developer then poured off, the picture will "come out," but will be of a feeble character throughout. The analogy to the present case of enlarging on paper is too obvious to require further explanation. The addition of a large proportion of glycerine or other inert (chemically) viscid substance to the developer will enable the paper to retain a larger amount of it and produce a more brilliant result.

Rapidity of development and brilliancy of the image greatly depend on the quantity of developer retained on the paper during exposure. The greater the quantity the more brilliant the picture and the more rapid the development.

The foregoing remarks apply to enlargements made in the ordinary horizontal enlarging apparatus, or made by means of a magic lantern. During enlargement the paper is supported in a vertical position. If the paper is supported in a horizontal position and a vertical enlarging apparatus used, the difficulty of keeping plenty of developer on at once vanishes, and vastly superior results can be had without difficulty.

A dish made of opal glass for the bottom, with varnished wooden edges, is most convenient for focussing, and then to support the paper during exposure and development. It is absolutely necessary to keep the dish perfectly flat. Any dish having a perfectly flat bottom may be used for the purpose. A piece of white paper in the bottom of a black *papier maché* tray does well enough for focussing on if an opal dish cannot be obtained.

An ordinary oil or limelight lantern may be converted into a vertical enlarging apparatus by the simple addition of a small mirror placed at an angle of 45° in front of its objective. A most desirable addition to the lantern is an archimedean screw studio stand. On this stand the lantern is placed with its mirror at the proper angle in front, the opal dish is placed perfectly level on the floor, and the negative from which the enlargement is to be made is put in the place usually occupied by the slide; the picture is then focussed in the dish on the floor by turning the screw of the stand.

A limelight lantern may be placed with the objective pointing downward, but is not so good an arrangement as the mirror dodge, because particles of broken lime are constantly dropping on the condenser.

When focussing is satisfactorily accomplished, the bromide paper should be placed dry in the dish and the developer poured over it and the dish kept in motion until the paper ceases to expand. The paper is now closely drained, which will have the effect of making it lie smoothly on the bottom of the dish. The dish carrying the paper is now replaced on the floor exactly in the same spot it occupied formerly. (This is most easily found by driving three nails in the floor in the form of a right angle for the dish to be pushed up against.) If the developer is poured very gently in the centre of the dish it will not raise the paper from the bottom, and in a few seconds it will spread itself evenly over the surface of the paper. The lantern may now be uncapped and the appearance of the image watched for. About one-sixteenth of an inch in depth of developer is sufficient.

P. SWANSON.

LEACH'S IMPROVED LANTERN MICROSCOPE.

THE principle upon which this microscope is constructed was briefly described in a paper which Mr. Leach read before the Manchester Microscopical Society on January 20, 1887, an abstract of which appeared in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, vol. xxxv., page 153. There was no thought when this paper was read of placing the microscope in the market, but the large amount of private correspondence which followed its publication, from many parts of

England, Wales, Scotland, Ireland, and America, led to the instrument being manufactured for sale.

The stage used in it was an old and well-known form, but it failed to give satisfaction, on account of the obstacles which the object-

can be obtained by one of the ordinary form when five inches in diameter.

When, as in using polarised light, it is not desired to be incommode with the wheel of diaphragms, the detachable plate carrying the compound wheel can be instantly detached and taken out of the stage, and when taken out can be as quickly put in again.

It should be noted that one stage serves for all classes of objects, whether ordinary microscope slides or polariscope crystals, shown with narrow angle rays or the convergent system of lenses. The tube for polarising prism is fitted for entire rotation, and all the phenomena of polarised light can be demonstrated by the instrument.

It is also equally useful for photo-micrography, as the optical principle is based upon the system introduced by the late Rev. T. W. Kingsley in the days of calotype photography, but greatly improved in both optical and mechanical details.

The large engraving will give an idea of the way in which the arrangement is used, a paraffin lamp with half an inch wick being the source of illumination for this purpose.

The instrument having been constructed by a working man (an operative photographer), who has devoted to it all his leisure hours for a period of over ten years, it has been deemed only fair that he

holder, with its four arms and the springs coiled round, offered both to the changing of the sub-condensers through the stage and to the attachment of a rotating tube for polarising prism. To get rid of these obstacles, a new arrangement of object-holder has been devised and placed underneath the stage, the arms passing through slots in the bottom, so as to hold the objects against the inside surface of the front of the stage. The new object-holder is thus placed out of the way of all the mechanism, and all the material used in the stage. In changing the sub-condensers, all which it is now necessary to do is to take out the one in use and put the other in its place, neither object, objective, nor wheel of diaphragms being disturbed in doing so.

The compound wheel of diaphragms is peculiar in its construction. One part of it has a large single aperture, and moves by means of an arm upon a pivot, so that it can be lifted up out of the field, or dropped into it, just as it is or is not wanted. A spring catch holds it up in its place, so that it cannot fall by its own weight. To the armed wheel is attached a second wheel with five concentric apertures, any of which can be turned into the centre of the field at pleasure. When the compound wheel is lifted up, as shown in the engraving, the whole field of the microscope can be utilised for showing objects up to one and a half inch in diameter. Thus the compound wheel, two and a half inches in diameter, yields just as large a field as

should seek some remuneration for his labour, and he has therefore secured his improvements to himself by patent.

ON A SIMPLE SUBSTAGE CONDENSER FOR THE MICROSCOPE.

ON the supposition that the following remarks may be of interest, I beg to offer them to your notice. They are founded on the application of a rather novel kind of substage condenser for the microscope, which has furnished me with some rather unexpected results, both visually and photographically. Whatever may be its real value, it has one claim which cannot be questioned, and that is its cost can be placed at zero. No doubt many of your readers have perused Professor Lowne's interesting article on *Interference Phenomena in Relation to True and False Images in Microscopy*, reported in the Journal of the Quekett Microscopical Club for April of this year. Professor Lowne suggests also a new theory for the formation of the diatom image when it is brighter than the field, and that "the cause of the positive image is that the diatom is illuminated from above, not from below. It is illuminated by reflected light from the upper surface of the front lens of the objective;" and the professor cites an experiment showing the "great illuminating power of the back of the

front lens of an objective." This surface of emergence of the front lens is a concave mirror, which condenses the reflected pencil upon the object. That such is the case to a certain extent is correct; but the following experiment will, I think, show it does not entirely suffice to form a bright image of the object in the case of diatoms. Having suggested to an eminent microscopist and photo-micrographer the use of a cylindrical lens of short focus for a certain purpose, and even hinting at a trial with a small piece of thermometer tube retaining the mercury column, under the supposition of the correctness of the argument used by Professor Lowne, thinking it might be possible that the bright, reflecting, flat surface of the mercury within the tube would aid the object in view by producing the desired image, I determined to test the same. At the time I was too unwell to carry out my suggestions, but I did so at the earliest moment, and my object in this article is to state the results.

The only properly constructed cylindrical lens I possessed was of too long a focus for the purpose, which was to try and render evident some doubtful markings, dots, lines, or areas on the diatom *amphipleura pellucida*. To construct a short-focus cylindrical lens means more time and trouble than I could give, so I cut off a piece of a thermometer tube half an inch long and from one-sixth to one-fifth of an inch in diameter, and having sealed in the small column of mercury, I mounted it centrally in a thin, flat piece of ebonite, as the first thing to hand. It was let into a slot diametrically, cut exactly to fit the tube lengthwise, keeping its surface parallel to the surface of the ebonite. The tube was thus held longitudinally at its widest diameter, the flat face of the little mercury column showing above and beneath. It was in this extemporised setting fitted on the top of the brass tube of a substage condenser without its lenses, but having its own rackwork, and being capable of rotation in the centring of the substage of the microscope. Here I had a kind of cylindrical lens formed round one axis of revolution, the central portion being blocked out by the small column of mercury. No time was lost to now test its value as a simple substage condenser for use on lined objects, and also as it appeared to me useful to test Professor Lowne's theory. After duly centring the mercury column, I placed on the stage a slide with *pleurosigma Balticum*, and by aid of the plain mirror and daylight, using the one-fifth objective and No. 1 eyepiece, I noticed that the bright reflecting surface of the mercury in the little tube did not suffice to give by its own light, reflected from the back of the front lens, more than a very faint image of the diatom; but the moment the small tube was decanted, so as to place the mercury column to one side, or just out of focus, I had a very beautiful image of the object, and could by rotation of the tube round the central axis of illumination easily bring out, separately, either the short horizontal lines or the longitudinal ones by alteration of this substage adaptation, or both, showing the markings or areas in squares. Another objective was tried, as Zeiss' E, equal to about one-ninth. Here the image was more perfect, only from its larger numerical aperture there was more difficulty to separate the striation. The next trial was to go over the same ground again, using simply the divergent rays of the microscope lamp, and with the same result. The divergent rays were next made parallel by a bull's-eye condenser, also by a crossed lens before reaching the small tube, which rendered this image very bright.

Having thus far satisfied myself, I next cut a small piece from a solid glass rod of about the same diameter. This was mounted more carefully, and upon testing its use in the same manner, I was greatly surprised at its efficiency when used to illuminate the same object, and also other diatoms. The extreme brightness of the images with a one-twelfth water immersion made by Gundlach, and selected for me years since by Mr. Winespeare, optician, Hull, for photo-micrography, when focused on *pleurosigma formosum*, led me to test its value photographically. Unfortunately, I had to fall back on some old slow quarter-plates, and being without any guide as to exposure, I simply made use of my small camera arrangement, described in one of your Almanacs, and attached it to the draw tube of the microscope, using for illumination a large paraffin lamp, and a crossed lens as a condenser. At the first trial a very fair image was obtained, using the developing solution described in the present BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC, 1890. It seemed evidently worth while to try another more magnified image, so I managed to centre a quarter-plate camera by means of a blackened card with a central dark-lined paper tube fitted to the draw tube of the microscope, and made to fill up the lens aperture in the camera. As soon as ready, I took a photo-micrograph of *pleurosigma formosum*, using the one-twelfth of an inch bull's-eye condenser and lamp, the little rod being set parallel to one set of lines on the diatom. The result I enclose for your notice, as it possibly may be one of the first negatives you may have seen produced under such conditions.* Unfortunately it is a

[* The result is excellent.—Ed.]

trifle over-developed, but with the naked eye, or better with a lens, you will see the effect that can be obtained by such a simple piece of apparatus. The value of the little rod as a condenser appears to me to rest chiefly in giving linear illumination of a convergent character, which can be directed in any position as regards the striation of lined objects. Some very curious effects can be brought out by keeping the eyes fixed on the object at the same time that the rod is gently rotated round the axis of the microscope, and it is just possible some of the peculiarities in the structure of striated diatoms may be better brought out than with an all-round convergent illumination. There is one point that must be carefully observed to obtain the best result, which is to be careful to use it at its own focus, otherwise the image is pale or fogged. It is not pretended to offer this plan for anything more than a *costless* substitute for a *costly* piece of apparatus. It possesses a certain value, but is not intended to compete in general excellence with a first-rate achromatic substage condenser. You will be able to judge for yourself. I should have liked to have tested rods of coloured glass, but could not put my hand on any suitable; and there remains yet to try the rod with a right-angle prism, instead of the plain mirror or parallel light by means of the bull's-eye condenser. To find the best position of the rod requires a little trouble.

It was intended to have made these remarks more complete, but as I may not immediately be able to follow up the subject, it was deemed best to furnish it, though incomplete, trusting you may be able to find room for it in your valuable columns, and the suggestion useful to your numerous readers, for I have only played the part of Captain Cuttle, and "made a note on't."

R. L. MADDOX, M.D., Hon. Fell. R.M.S.

CELLULOID FILMS FOR THE LANTERN.

AMONG the published references to that new and beautiful material, celluloid, which is being used as a support for gelatine emulsion in lieu of glass (and with every prospect of largely supplanting that heavy and brittle substance), I have not seen any mention of its possible use for lantern slides. Having used the lantern during the past twenty years to illustrate lectures given in many parts of the United Kingdom, I think that fellow-workers will agree with me, that if we can substitute the light, unbreakable celluloid for the heavy and brittle glass it will be a very great advantage indeed.

The lot of the travelling lecturer with the lantern is not a very "happy one." In addition to the case or cases containing his lanterns, bags, &c., he has to carry a number of slides on glass (each slide requiring two plates of glass), which can seldom be fewer than sixty, and which may be several hundreds, in number, if his absence from home extend over several days and include the delivery of several lectures.

The wooden cases or parcels containing these precious glass slides the lecturer fears to let out of his own hands. He has seen them dropped or carelessly used by porters and assistants, and perhaps has bitter remembrances of lectures previously marred by the breakage of some of his best slides.

How pleasant to be able to replace the glass by a film not one-twelfth the weight of glass, and parcels of which may be dropped or even thrown about with little fear of injury. One envelope will suffice to contain the film-bearing slides for one lecture, and with two or three holders for the films the equipment in this respect will be complete.

The questions of course arise: Is it possible to get pictures of sufficiently good quality for use in the lantern upon celluloid? Will they be transparent enough, will they lie flat, and can they be used safely in such a "hot place?"

I have lately obtained from Mr. Fitch, of 34, Angell-road, S.W., some stout films of celluloid (thickness about one-fiftieth of an inch) cut to lantern size (three and a quarter inches square) with both sides smooth, and coated with excellent gelatine emulsion. The celluloid films for ordinary work have one side finely ground ("matt") in order to enable the emulsion to adhere more firmly. But I think its use must be mainly to lessen halation, for on these smooth films which I have been using for lantern slides the film adheres perfectly without a trace of frilling, &c., although I have not even used an alum bath for them.

The exposure for the celluloid films which I have given when printing by contact has been seven seconds for an average negative at a distance of three feet from an ordinary gas burner. This indicates that the emulsion is more rapid than that ordinarily used for coating glass lantern slides, and there will be a considerable gain of time in using the celluloid films for copying in the camera. Although the emulsion is rather rapid, yet it has great latitude.

For development, use saturated solution of potash oxalate and ferrous sulphate (each being made just acid to litmus paper by the addition of a few drops of acetic acid), adding one part of the latter to

light of the former, with the addition of three or four drops of a ten per cent. solution of potassium bromide for each ounce of developer. If hydroquinone is preferred, use five grains of that substance with twenty grains of sulphite of soda, fifteen grains of carbonate of potash (anhydrous), and three drops of a ten per cent. solution of potassium bromide to each ounce of distilled water. Don't soak the film before developing, but put in the dish, pour the developing solution over it, and then brush the film well with a flat camel-hair brush, or pass a small pad of cotton wool over it a few times to prevent the formation of air bubbles.

The image must be judged not by reflected but by transmitted light. When the picture begins to look dark and somewhat sunken in (as viewed when looking down upon it), take it out of the dish and hold it quite close to your lamp. If it then looks (by transmitted light) a little too dark, the development is complete. Now rinse well, and immerse in fresh clear hypo of ordinary strength. Fixing is, if anything, more rapid than with emulsion upon glass.

The celluloid films, though thin, are so rigid, that in this small size they will stand vertically to wash in the grooves of an ordinary washing tank; or they may be laid on their backs at the bottom of a large flat dish through which a current of water is kept flowing.

When sufficiently washed, I lightly rub the film with a pad of clean cotton wool to remove the minute impurities which ordinary water deposits on the surface. They are then blotted between two or three thicknesses of blotting paper (to remove the surface moisture), and laid (film upward) on a piece of blotting paper to dry. If placed on the mantelpiece of a warm room the films will dry in an hour or even less, and will be quite flat and ready for use.

The film surface may then be varnished, if desired, with crystalline varnish, laid on cold with a brush. To say that these celluloid lantern films are at present quite equal to glass in transparency would not be correct; but there is so little difference in this respect that their other advantages far out-balance it.

For exposure in the lantern, the films might be held together by small steel clips at the four corners, so as to form a band, which could then be drawn through the instrument. The ideal lantern band, however, would be a series of pictures printed in their proper order on one long sheet of celluloid. This could be placed on a roller slide adapted to the lantern, and the pictures would continuously off one roller on to the other. Perhaps printing matters might be so contrived that the new Eastman negative "rollable" film which we are promised could be developed, &c., in one piece without cutting up, and then printing on by pressing a second positive "rollable" film into contact with it on a cylinder.

In the meantime it will probably be best to use our celluloid lantern films just like glass plates. As they are so thin, and to ensure their flatness, it may be necessary to put them in some sort of holder before inserting them in the lantern; but this need be a matter of little difficulty, and two or three holders would suffice (by changing) for any number of films. Hinged wooden or metal holders, between which the film might be placed and then clipped: a plain wooden or metal case with a rabbet on which the film would lie, being then held down by a second light frame pressed into the rabbet, answers well. Any number of such contrivances will suggest themselves, and it is to be hoped that no attempts will be made to patent them.

Celluloid is inflammable, and it is just possible that in a badly ventilated lantern, if a celluloid film were kept "on the screen" for half an hour, it might ignite. I have not applied such a severe test, but it might be thought necessary the heat rays can be almost entirely eliminated by interposing a glass cell containing alum water between the light and the film.

With this note I enclose for the Editor's inspection a lantern slide on celluloid (one of a batch of twelve) just made by contact printing. It was simply developed, fixed, washed, and dried—no aluming or clearing solutions being used—and the whole was completed in less than an hour. Of course, a longer washing would have been better, but to be able to make slides at this rate is often a great convenience to a lecturer.

I simply slip the celluloid film between the pages of my note, and I feel tolerably sure of its safe carriage. What would be the fate of a glass slide sent through the post in like manner?

W. JEROME HARRISON.

DARKENED SILVER CHLORIDE NOT AN OXYCHLORIDE.

About two years ago I published a series of papers in *The American Journal of Science*, the main object of which may be briefly stated as follows:—To prove that the substances which I described as "photo-salts" and obtained by purely chemical means were identical with those produced by light, with both the visibly darkened substances, and the

material of the latent image. Further, that all these substances consisted of a silver haloid (normal chloride, bromide, or iodide) combined with the corresponding subsalt, not in equivalent proportions, but after the manner of a "lake." The subsalts, being unstable substances when isolated, acquiring much greater stability by the union.

The only objections I have seen to these views were based on investigations made in England by Dr. Hodgkinson; his conclusions were that an oxy-salt and not a sub-salt was formed. Although several years have elapsed since these conclusions were made public, the means by which they were reached, and the necessary experimental proof, do not seem to have been published. Mr. Meldola, in his interesting *Chemistry of Photography*, in treating of this part of the subject, seems disposed to accept Dr. Hodgkinson's theory and his formula, Ag_4OCl_2 , for darkened silver chloride. Mr. Meldola adopts my views that the photo-salts which I described, and which were obtained by purely chemical means, are identical with the products resulting from the action of light on the silver haloid, but expresses the opinion that I have not proved my theory of their constitution.

It has always seemed to me that the whole mass of observation on the action of light on silver chloride tended so thoroughly to indicate the formation of subchloride, that we might reasonably accept that view, at least, until something in the way of proof were offered for the oxychloride theory. But, waiving this objection, I will endeavour to show that subchloride and not oxychloride is the product of the action of light on silver chloride.

The question as to the presence or absence of oxygen in coloured silver chloride is one that cannot be determined satisfactorily by quantitative analysis. Taking, for example, the formula just mentioned, Ag_4OCl_2 , it would involve the presence of about three per cent. of oxygen if the entire mass of silver chloride were converted into this substance. But we know that even by the longest exposure the proportion of AgCl acted upon is very small. It would probably be a liberal estimate if we were to fix five per cent. of the whole mass as the proportion changed by light, so that the amount of oxygen that would—according to the oxychloride theory—be introduced into a given quantity of chloride by prolonged exposure would not exceed three-twentieths, or 0.15 of one per cent., of the material under examination—a dangerously small quantity on which to attempt to decide an important question, especially where the estimation is indirect. If even a very careful determination of the silver and the chloride present should bring the sum of these to a quantity represented by figures amounting to from 99.80 to 99.90, would it be allowable to assume that the difference between this and 100 consisted of oxygen, and so to take the presence of an oxychloride as proved? Such reasoning could not be accepted; the errors, incident to the most careful analysis, would too largely affect the point vitally at issue, not to speak of the entire absence of proof that the deficient quantity was oxygen.

These considerations convinced me that it was not in that direction that one should seek for proof of the presence or absence of oxygen in the substance in question. I therefore looked for what may be called *proof by exclusion*.

Coal naphtha (refined petroleum) is a substance absolutely free from suspicion of containing oxygen or moisture as impurities, so much so as to be universally used for the preservation of sodium. I have sodium that has been preserved in this way for over thirty years. Silver chloride was precipitated with excess of hydrochloric acid, was washed in a darkened room, and dried in a desiccator. From this it was transferred to a porcelain crucible, covered, and fused over a lamp. When thoroughly fused (in this condition it is as fluid as water) it was poured directly into naphtha. This naphtha had been placed to the depth of an inch or more in a dry porcelain vessel which was first well wiped out with naphtha to remove the film of atmospheric moisture which condenses on surfaces.

The chloride congealed into a pale grey lump, which, whilst it remained under the petroleum, was absolutely free from all possibility of contact with oxygen, free or combined. Without removing it, the vessel was moved into the sunshine; when touched by sunlight, the chloride instantly became as black as ink.

This experiment seems decisive as to the oxychloride theory.

It seemed desirable not to stop here, but to find a means of applying an equally decisive proof by exclusion to the converse case. In the above instance, a photo-salt was formed by reduction, starting with normal chloride. The converse case would be the formation of a photo-salt by chlorination, starting with metallic silver, and excluding oxygen, free or combined, thus demonstrating that that element is not needed, and plays no necessary part in the formation of silver photo-chloride.

Anhydrous cupric chloride, which I at first thought of employing, proved to be insoluble in naphtha. In rendering ferric chloride anhydrous, there-

is a possibility of forming oxychloride; it could therefore not be employed. As it is not in the least important which halogen is used I concluded to take iodine, which proved to be slightly soluble in naphtha, with a beautiful violet colouration. The mode of operation was as follows:—Pure silver reduced by cadmium from the chloride was heated nearly to redness in a porcelain capsule, and at the instant of removal from the flame was dropped into naphtha. Some fragments of iodine were added. Owing to the very small amount of iodine soluble in naphtha the action was slow, but continuous and regular. As fast as the iodine was dissolved it was taken up by the silver. At the end of some hours the iodine had disappeared wholly, and the naphtha was colourless. Fresh naphtha replacing it failed to dissolve any iodine; the whole of it had combined with the silver to a black compound. This experiment may be varied by using a piece of clean silver foil, or even a silver coin that has been boiled a few moments with nitric acid, washed, and heated by a blast lamp; immersed in the naphtha with iodine its surface soon becomes perfectly black.

This reaction forms the complement of the other, and the two show that whether we start from silver chloride and proceed by reduction, or from metallic silver and proceed by iodisation, in either case we can obtain a photo-salt under conditions which rigorously exclude all possibility of the presence of moisture or of oxygen in any shape.

Therefore the photo-salt is not an oxy-salt, but, as I endeavoured to prove two years ago, a compound of normal salt with subsalt.

The action of light upon silver chloride appears to take place in the following manner:—If any substance is present with which chloride can combine, either directly or by substitution,* the AgCl is decomposed with formation of subchloride. As the product is subchloride and not oxychloride, it is not necessary that the substances present should contain oxygen, as has just been shown. The subchloride thus formed instantly combines with a portion of the silver chloride as yet unacted upon by light, forming a photo-chloride of great stability, capable, for a time, of resisting the action of nitric acid. (I have shown that the photo-chloride made by purely chemical means also shows this stability.)

This combination is not by equivalents, but it is of the nature of a lake, and the affinity of silver chloride for the subsalt is of a progressively diminishing character. Small quantities of subchloride are held with great tenacity; as the proportion of subchloride increases the affinity diminishes. This is no assumption; it is easy to form chemical photo-chloride containing a large proportion of subchloride. Much of this latter is instantly decomposed by old nitric acid; with heat an additional quantity disappears, and so on, until the last portions may require hours of boiling with strong acid for decomposition.

This stable combination of the chloride and subchloride constitutes alike the material of darkened chloride, of the latent image, and of the photo-chloride.

An excellent mode of testing the value of a chemical theory is to observe its ability to explain, not only the general result of a reaction, but also the secondary facts observable. In the present matter—the action of light on silver chloride—there are two such secondary facts of a quite remarkable nature, for which, though long familiarly known, no explanation has hitherto been found, but which, I think, will be found to be readily and satisfactorily explained by the photo-chloride theory.

1. When silver chloride is exposed to light, there is a certain pause, an interval, during which very little action takes place. After this the darkening acts in rapidly; this fact is so conspicuous as to attract the attention of every one who exposes chloride paper.

The explanation is:—Light pink or violet photo-chloride is vastly more sensitive to light than white chloride, a fact easily proved by preparing light-coloured photo-chloride by any of the chemical means I have elsewhere described, brushing it and white chloride, each in a pasty condition, over respective strips of paper and exposing side by side; the difference in the darkening is very striking. Now, the first action of light on white chloride is to form this light-coloured photo-chloride, and whilst that is going on but little visible effect is produced. As soon as the photo-chloride is once formed the darkening becomes rapid. The time required for the first formation of the photo-chloride gives rise to the pause which is observable.

2. When pure, moist, silver chloride is exposed to light, the darkening goes on steadily to a certain point, and then virtually ceases. Although

* As to the action of light on silver chloride perfectly isolated, i.e., in a perfect vacuum, it would appear, from an interesting experiment of Abney's, that no decomposition takes place. It was found that AgCl in vacuo did not darken, even by prolonged exposure.

This experiment does not indicate that the presence of moisture is essential for decomposition; it simply proves that some substance (by no means necessarily water) must be present upon which chlorine can act. Accordingly, when the vacuum tube contained mercury, the AgCl was decomposed by exposure to light. It may be remarked that this last-mentioned fact, properly considered, would have been found to be fatal to the oxychloride theory, inasmuch as darkened chloride was formed in the total absence of oxygen.

the mass may be constantly agitated so as to expose fresh portions whilst it is kept moist, or, better, kept under water, the action of light after a few days' exposure ends almost wholly, and though the chloride now seems perfectly black, analysis shows that the amount of chloride altered has been very small—perhaps a twentieth. For this well-known and most remarkable fact I believe no explanation has ever been offered.

It is to be explained, I think, as follows:—When light acts on moist silver chloride, acid products are formed the nature of which has not been fully made out, but whose presence is certain. (If the exposure is made under water, the water reddens litmus; it does not bleach it.) These acid products would instantly destroy silver subchloride isolated. As long as the quantity of subchloride present, and combined with normal chloride, is small, the protecting power of the normal chloride saves the subchloride from decomposition. The ability of normal chloride to protect the subsalt rapidly diminishes, as already mentioned, as the proportion of the latter increases. These forces in time find an equilibrium (as in the case of many other chemical reactions) in which the quantity of subchloride becomes constant, and any excess that is formed by light beyond the quantity which the chloride can protect is instantly destroyed; consequently, even the most protracted exposure fails to increase the proportion of subchloride beyond its limit.

The complete cessation of the reducing action of light, after a certain very small fraction of the chloride present has been attacked, cannot be explained by the oxy-salt theory; for, if a small portion of the chloride has been converted into Ag_2OCl_2 , there is no conceivable reason why a continuance of the same agencies at work should not affect the residue, and so go on until the whole of the silver chloride passes into the new condition. No theory deserves serious consideration that does not offer a satisfactory explanation of these two conspicuous facts: the pause at the outset, and the cessation of action as soon as a certain small proportion of chloride is reduced.

A confirmation of the explanation here offered is to be found in the fact that black forms of photo-chloride, chemically formed, are almost wholly unacted on by light. By treating metallic silver in a state of fine division* with sodium hypo-chlorite, black photo-chloride is easily formed, which, after two or three treatments with hypo-chlorite solution, gives up nothing to cold nitric acid. It is almost wholly insensitive to light, because as fast as normal chloride is decomposed by light it is reconstituted by the conversion of a corresponding quantity of subchloride present to normal chloride. The chloride and subchloride are in an equilibrium, which the action of light does not alter.

M. CAREY LEA.

Foreign Notes and News.

THE German Emperor, on his recent voyage in the Mediterranean to Athens and Constantinople, took especial pleasure in causing from time to time a number of views of the deck of his vessel to be taken, presumably by that favoured individual known as "Hof Photograph." It is possible that his Imperial Majesty may have attempted to beguile the tedium of his voyage with a perusal of some of those *critiques* that have recently appeared in various English photographic publications, the tendency of which has been to show that the principal merit of the old masters lay in their successful grouping—the technical execution of their works being a comparatively insignificant matter from the artistic point of view. Whether or not his Majesty has become a convert to this "higher criticism," he, on one occasion, when the above-mentioned Court photographer was getting things ready for an exposure, undertook to act as poser in chief to that functionary himself. He thereupon ordered his crew about—the one man to lie down, the other to stand up, some to swarm the shrouds, others, doubtless, to haul home cables, weigh anchor, and tug at running gear, halyards, and brail, and when their situations were sufficiently varied and picturesque to please the Imperial artistic sense, the Imperial voice exclaimed in sonorous tones "Ready," and the Imperial Court photographer let fly and registered the result. The resulting negative will probably be as valuable an "historic *souvenir*" as the pen-knife which his Majesty borrowed at a banquet to cut a cigar, and perhaps will have the invaluable effect of strengthening the higher art criticism alluded to above by exhibiting an Emperor as one of its disciples.

HERR JACOB JUNK has recently invented and introduced in Germany a new bromide of silver printing paper without gelatine. A number of specimens of prints obtained with it were exhibited at the last meeting of the Photographischer Verein, in Berlin. Among these an enlargement of an architectural view was conspicuous for its excellent tone obtained without any retouching. An excellently executed portrait enlargement gave

* For such purposes, metallic silver is best obtained by precipitating the nitrate with sodium hydroxide in excess, and, without washing, adding a solution of milk sugar. In a few hours the reaction is complete (Levol's method). If the presence of any undecomposed oxide is feared, the product may be washed with ammonia.

evidence of the fact that this material is one which can be worked upon both with pencil and crayons perfectly satisfactorily. All the difficulties previously experienced in attempting to colour bromide of silver paper, on account of the impermeable film, are obviated by the use of this material; and the meeting was unanimous in regard to the high value of the new invention, Dr. Meyderbauer being especially enthusiastic in his encomiums.

APPROF of an acid fixing bath, it is pointed out by A. Lainer, in the *Photographische Correspondenz*, that it hardens and contracts the gelatine. To prove this he softened two sheets of gelatine of fifty-five millimetres length in water, which caused an elongation of two millimetres. One of these leaves, when placed in an acid fixing bath, in ten minutes contracted to its original length, becoming, at the same time, harder and thinner; the other, being placed in the ordinary fixing bath, became somewhat longer and thicker—facts which speak considerably in favour of the acid bath.

GASTINE, in the *Moniteur de la Photographie*, gives the following receipt for platinum toning. Dissolve, not above 55° C., 20 parts chloride of sodium and 10 parts double tartrate of sodium in 300 parts water; add, while stirring, 5 to 7 parts of a solution of platinum chloride 1 to 10, and dilute the lot to 1000 parts.

MR. T. H. DUFFIELD will probably be pleased to hear that his excellent article on detective cameras is being translated or summarised in nearly all the principal photographic journals of the Continent.

DR. MIETHE has recently published a treatise, entitled *Zur Actinometrie Astronomisch-Photographischer Fixstern Aufnahmen*, which will be received with considerable attention by all who are interested in the application of photography to astronomical purposes. The principle which formed the starting-point of the researches of which the book in question contains an account, is that enunciated some time ago by Janssen, that the density of the developed image of a star is directly proportional to its light intensity when the period of exposure is the same for the stars compared. Against this position practical astronomers had maintained that experience showed that the difference of density in the images of stars of different brightness could not be equalised by merely lengthening the exposure, and that the image of the less bright stars, no matter how long the exposure, always appeared fainter. The result of Dr. Miethe's researches, which have been extended to include all the different coloured stars, goes to show that, within certain very wide limits, the facts correspond very nearly with Janssen's law, but that when ordinary non-orthochromatic plates are used density increases much more slowly in proportion to the time of exposure in the case of red and yellow stars than in the case of blue or violet stars—a fact which explains the discrepancy hitherto observed between Janssen's principle and actual fact in a variety of instances—faint stars being usually yellowish rather than blue.

PATENTS COMPLETED.

IMPROVEMENTS IN OR RELATING TO MIXTURES OR SOLUTIONS FOR DEVELOPING OR FIXING THE LATENT IMAGES ON PHOTOGRAPHIC PLATES OR SHEETS.

(A communication from abroad by CHARLES SPIRO, of the City, County, and State of New York, in the United States of America, Gentleman.)

No. 13,523. WILLIAM PHILLIPS THOMPSON, F.C.S., M.I.M.E., of the Agency for Foreign Patent Solicitors, 6, Lord-street, Liverpool, and 6, Bank-street, Manchester, both in the County of Lancaster, and 323, High Holborn, in the County of Middlesex.—*November 9, 1889.*

This invention relates partly to means for developing the latent images of photographic plates or sheets without a dark room, and has partly for its object to provide a developing mixture whereby a complete isolation of actinic rays of light from the developing photographic plate or sheet will be secured, while a clear view of the developing image may be obtained.

In developing a photographic plate or sheet in a dark room, as heretofore, in which the only light was the dim light admitted through ruby or orange-coloured glass used to exclude the actinic rays, it was possible for the operator to watch the progress of, and control, the development only by removing the plate or sheet from the developing bath from time to time and holding it up to the light for inspection, which process was wearisome and, in many instances,

destructive to the plate, owing to the incomplete exclusion of the actinic rays and the, perhaps, extreme sensitiveness of the plate.

To avoid these inconveniences and attain the objects of the invention, a mixture is provided consisting of any of the ordinary and well-known developers, such as pyrogallie acid and soda, or hydroquinone, in combination with a non-actinic, transparent colouring matter, preferably orange aniline, or a mixture of the same and carmine aniline, where the plate or sheet to be developed is very sensitive.

In preparing this non-actinic developing mixture, at present, the inventor takes, preferably, hydroquinone for the developer, and to one pint thereof adds a solution composed of equal parts of alcohol and water (to energise the solution) to make one ounce, and two parts of orange aniline and one part of carmine to make half an ounce, thoroughly mixed so as to form a completely saturated and dark orange-coloured solution of diluted alcohol.

This solution is first well strained to remove all extraneous matter, and then combined with the developer, as before stated.

This mixture is poured into a developing tray, and the photographic plate or sheet to be developed transferred from the plate holder into the non-actinic bath thus prepared, either in the dark room, afterwards admitting the light thereto, or removing the bath with the contained plate into the light, or by any well known or approved means for effecting this transfer in the light without exposing the plate or sheet thereto.

The non-actinic bath will completely exclude the actinic rays from the immersed plate or sheet, and, the developing mixture being perfectly clear, the development will proceed in full view of the operator, who may thus easily note the progress of the development.

When the image is found to be fully developed, the plate or sheet may be transferred in the light to a bath of any of the usual fixing agents, such as hyposulphite of soda, and the bath quickly covered with a dark cloth; or the fixing bath may be likewise rendered non-actinic by the addition thereto of the same non-actinic colouring matter.

The transfer of the developed plate or sheet from the non-actinic developing bath into the fixing bath in the light may be thus effected without clouding the image, inasmuch as the aniline colouring matter forms a perfect solution and fills the pores of the gelatine film, so as to form a perfectly non-actinic envelope over the film, lasting until the plate is immersed in the fixing bath. The fixing action then immediately commencing, light has no further effect on the film.

The proportions of the developer and coloured solutions above given will yield a safe and efficient developer, if the tray is no larger than necessary to be half filled by the mixture. But the circumstances of the case and the experience of the operator will determine the depth of colour in the mixture.

The right is hereby reserved to make future application for the non-actinic fixing mixture hereinbefore referred to.

Claims:—1. The combination, with a photographic developer, of a non-actinic transparent colouring matter, substantially as and for the purpose specified. 2. The combination, with a photographic developer, of a non-actinic solution of aniline colouring matter, substantially as and for the purpose specified. 3. The combination, with a photographic developer, of orange aniline, substantially as and for the purpose specified.

IMPROVEMENTS IN PHOTOGRAPHERS' PRINTING FRAMES.

No. 16,827. ALBERT TOWERS, 1, Victoria-terrace, Egerton-street, New Brighton, Cheshire.—*November 9, 1889.*

A SPRING attached to photographers' printing frames for printing from negatives. I place my spring at the back of the frame as is usual in these frames, but secured so as to have no sliding action. The springs heretofore in use are usually secured to the frames by a pin, rivet, or screw, and move upon it as a centre in applying or removing the pressure of the spring to the pressure board or back, the sliding action of the spring, so worked, acting upon the pressure board or back causes it to move, thereby causing a corresponding movement in the negative or sensitised paper, damaging or destroying the copy.

My improvement is a bow spring hinged to the side of the frame at the back, so that direct pressure only is applied to the pressure board when applying or removing its pressure, all sliding action being avoided, and the securing of the spring when pressed down, by an arrangement similar in action to an ordinary bolt for doors.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE ordinary monthly meeting of this Society was held on Tuesday last,—Mr. James Glashier (President) in the chair.

The formal business was soon transacted, when Mr. G. H. WHIPPLE, the Superintendent of the Kew Observatory, discoursed upon *The Applications of Photography to Meteorological Purposes*, Mr. Debenham's paper on *The Estimation of the Efficiency of Plate Backings* having been postponed in consequence of a death in that gentleman's family.

Mr. Whipple introduced his subject by referring to his early applications of photography to the registration of meteorological phenomena, more notably the early barograph, described by Mr. Jordan in the *Transactions of the Polytechnic Society* in 1833. In this case light shining across the vacuum space over the mercury column acted on a band of sensitive material which was wound on a clock-driven drum. The speaker also referred to the early labours of Ronaldi in photographically recording electric and other atmospheric changes. After thus introducing the subject, he described in detail the Kew recording instruments as used at present, not only at Kew but at the numerous other meteorological stations where the Kew system has been adopted. Mr. Whipple's plan of demonstrating was, in the case of instruments too complex or too large to be actually shown, to first project on the screen photographs of the apparatus and then schematic diagrams of the essential parts. In the case of the barograph he made very clear how the barometric column was photographed every alternate hour, a small gas jet serving to illuminate the empty part of the tube, and a portrait was used to project the image of the top of the mercury column on to the sensitive paper which clothes the revolving drum. Afterwards the magnetographs were described, and the arrangement of the second mirror, the reflection from which gives the datum line, was explained. In the case of the thermograph two thermometers are used, one dry bulb and the other wet bulb, and the recording ray shines through a break in the mercury column. The various sunshine recorders were afterwards described, after which some account was given of the various photographic methods employed, which ranged from the old Talbotype and the Daguerreotype to gelatino-bromide paper, which is now exclusively used; but until quite recently waxed paper was made use of.

Mr. Slingby exhibited some flash-light groups.

A number of new members were elected, and it was announced that the next meeting (technical meeting) would be held on the 31st inst.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 5.—Mr. G. W. Atkins in the chair.

Mr. A. COWAN showed the results of some experiments in the use of carbonate of ammonia in connexion with hydroquinone and eikonogen developers. The effect of the addition of carbonate of ammonia to either of these developers when already containing carbonate of soda was to cause the action to be slower by about five times; at the same time the image acquired a more sunk-in appearance, not important except if required for positives by reflected light; there was also a certain amount of stain or green fog on the film.

Mr. J. B. R. WELLINGTON had noticed the same effect, but had overcome the green fog by the use of bromide. The development was very much slowed unless a very long exposure was given.

Mr. J. J. LIZELL then gave a demonstration of the use of the air pencil, an instrument very similar to the air brush, but lighter and more compact in form. Drawings representing portions of the human face and figure were shown, and similar ones were rapidly produced by the operator. It was pointed out that negatives as well as prints might be readily improved by skilful retouching with the aid of this instrument. For putting in a background to a photograph, a duplicate print of the head was laid so as to shield the face from the spray played on to the background. By keeping this mask print a little distance away from the one below it, the edge was softened. A piece of wire gauze laid on the print caused the spray to assume something like a stippled appearance.

Mr. A. HADDON suggested that a very useful application of the instrument would be to make vignetting forms by playing the spray on to tissue paper.

Mr. ARCHER CLARKE showed a positive printed on celluloid, and complained of the yellowness of the whites, inquiring whether better examples of the process could not be found.

Mr. COWAN raised a corner of the gelatine film and found that the yellowness was not in the celluloid underneath, but only in the film.

Mr. WELLINGTON noticed that Mr. Cembrano had stated that washing soda gives yellow negatives, but that pure carbonate of soda did not. He (Mr. Wellington) had not found the difference in his own experience.

Other members spoke to having used the ordinary washing soda without noticing any yellowness, or any difference between the action of that and of the pure carbonate.

CAMERA CLUB.

On Thursday, December 5, Mr. A. HORSLEY HIXTON read a paper entitled *The Standard of Excellence in our Art*.—Major J. F. Nott in the chair.

Previous to the reading of the paper the Secretary placed on the table a handy vignetting arrangement sent by Messrs. Marion & Co. for exhibition; also a convenient lecturer's reading desk and shaded lamp for use in optical lantern lectures, which had been devised by Mr. H. A. Arnaud, of Ryde. In this a battery is provided for communication between the lecturer and the lantern operator, and the whole is arranged for fixing to an ordinary tripod if desired. The apparatus, which is called the "Perfect lecturer's desk," is being brought out by Messrs. Negretti & Zambra.

Mr. Hixton's lecture was a carefully thought-out treatise dealing with the present aspect of photography as a fine art, and referring to questions just now of special interest in photographic circles. He maintained that good art is never reached by chance, but is intellectual; and he drew a marked distinction between the scientific and artistic way of looking at natural scenes and objects.

In the discussion which followed remarks were made by Mr. Davison, Rev. A. B. Whiston, Dr. Patterson, and the Chairman.

The subject on Thursday, December 19, will be *Sitting and Erecting Ordinary Drawing Papers*, when Mr. Lyonel Clark will read a paper and give a demonstration. Meeting at eight p.m.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

DECEMBER 3.—Mr. A. Mackie in the chair.

The President (Mr. J. Traill Taylor) presented a bound volume of *THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC* for 1890.

The Hon. SECRETARY exhibited and explained a Thornton-Pickard instantaneous and time shutter, which was considered a very good instrument.

Mr. T. Lawday showed a print on albumenised paper with several streaky marks across.

Mr. MACKIE explained that the albumen had cracked before printing, through the paper becoming too dry.

Mr. W. BISHOP then gave a demonstration of *Lantern Slide Making*. After referring to the history of photographic lantern slides from the days of wet collodion, through the gelatino-chloride plates of Edwards, Cowan, and Warnerke, to the bromide plates of the present day, he said that lantern slides were of two classes—those made in the camera and those printed by contact with the negative. Dealing with the first class, a simple form of apparatus was illustrated on the blackboard, after which the production of slides by contact was demonstrated by the exposure, development, and fixing of a number of plates, both hydroquinone and eikonogen being used as developers. Cleaning emulsion from the backs (by means of Sapolio), varnishing, masking, and finishing were successively dealt with; the adoption of distinctive colours for binding being recommended, and the proper marking of the top of the face of the completed slide being insisted on. Mr. Bishop further said that, although the actual demonstration had been confined to Thomas's plates, he wished to acknowledge the courtesy he had received from the Britannia Works Company in answer to inquiries, and he exhibited a frame of twelve slides, which he had printed on that Company's new "Alpha" plates, showing the richness and gradation of tone obtainable with them by various modifications of exposure and development. These excited much interest.

Mr. MACKIE then exposed and successfully developed a collodio-bromide emulsion slide, the rapidity of the operation attracting considerable attention.

Referring to marking slides, Mr. TAYLOR said that the Birmingham Society had adapted a white line along the top with particulars of the subjects written on.

Mr. L. MEDLAND stated that he had used a baking dish with hot water under for quickly drying collodio-bromide plates; he also found it desirable to gum the binding slips about three times, to prevent their coming off with heat.

Mr. BISHOP found that paste was better for binding slides than gum, as it did not crack off, and that the hydroquinone developer could be used many times and yet develop well, only requiring rather longer time.

Mr. NEWMAN then showed and explained an ingenious hand camera. On December 17 the Platinotype Company will give a demonstration.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

DECEMBER 6.—The President (Mr. F. W. Edwards) in the chair.

Mr. JOHN HOWSON (Britannia Works Company) attended and read a paper on *Enlarging and Contact Printing on Bromide Paper*.

Messrs. Thomas Cadett and Kirby were elected members, and two other gentlemen proposed.

Friday, the 20th inst., being a lantern night, the meeting will be held at Shawbury Hall, Lordship-lane, S.E.

LEWES PHOTOGRAPHIC SOCIETY.

DECEMBER 3.—The President in the chair.

Mr. A. R. DRESSER read a paper on *Hand Cameras*. He brought several hand cameras for inspection, including the one he used himself. Mr. J. Fallowfield sent a specimen of the "Facile," and Messrs. Harlestone & Co. the "Hawkeye," sold by Messrs. S. Fry & Co. On the walls were exhibited a fine collection of enlargements from hand-camera negatives by Mr. Dresser, and at the conclusion of the paper he exhibited about one hundred slides by the lantern.

BOLTON PHOTOGRAPHIC SOCIETY.

DECEMBER 5.—Mr. E. N. Ashworth presiding.

Mr. C. K. Dalton showed Hughes's metal lantern slide binders, and Mr. W. Banks a 15 x 12 enlarging camera.

Mr. CHARLES J. P. FULLER then read a paper on *The Attainment of Permanence in Silver Albumenised Prints*. He considered more prints faded from insufficient fixing than from anything else. He advocated the use of two hypo baths, as he found that hypo and silver in certain proportions formed an insoluble compound of hyposulphite of silver, which could not be washed out, but which if it had been placed in a second bath would have been dissolved.

COVENTRY AND MIDLAND PHOTOGRAPHIC SOCIETY.

DECEMBER 4.—Mr. President Andrews in the chair, and a fair attendance of members.

After the transaction of routine business, Mr. H. STURMEY proceeded to give his demonstration of *The Cold Bath Platinotype Process*. Commencing by describing the printing operations, he remarked that he was in some doubt as to the success of his exposition that evening, as the paper on which his prints were prepared had been purchased over six months ago, and some of the prepared prints had been done over a month; and, further, that they had not been stored, as directed in the instructions, in a calcium tube, but merely in that in which the paper is sent out, which had been kept in his dark room without any special effort to prevent access of damp. However, after a full description of the process, development was proceeded with, and all the prints (with one exception, which was over-printed) came up remarkably well, a fact which speaks highly for the keeping qualities of the paper.

In the discussion that followed, in reply to a question as to permanence, Mr. JONES, F.C.S., stated that he had subjected a print by the process to some tests, such as boiling in dilute hydrochloric acid, without the image being affected, although the paper support suffered total destruction.

Many members expressed it as their opinion that the instructions sent out with the paper were such as would deter many from availing themselves of the many advantages of the paper, but after having seen the process demonstrated they would no longer be afraid to take it up.

Prints developed by the brush method were shown by Mr. F. W. DEW, who also detailed some experiences in working.

A hearty vote of thanks was accorded to Mr. Sturmev for his instructive paper.

The President handed round a negative and also a print from an enlarged negative of the same, showing how an original which might be too thin to be of use (as this one was) could be reproduced in a satisfactory manner.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

DECEMBER 5.

A practical demonstration by the SECRETARY (Mr. E. Beck) of *How to Use an Optical Lantern, with special reference to the Oxyhydrogen Limelight*, was given. He said that members and the public generally had got a notion that the use of the steel cylinder was highly dangerous and difficult to manage, whereas it was really as safe, if not safer, than the old-fashioned gas bag; mere portable, and, if anything, easier to manage.

Thereafter a number of slides were exhibited by the lantern, and fully appreciated.

HUDDERSFIELD PHOTOGRAPHIC SOCIETY.

DECEMBER 4.—Mr. W. H. Charlesworth in the chair.

Mr. H. M. SMITH, of the Eastman Dry Plate Company, gave a lecture on *The Method of Making Enlargements on Bromide Paper*. He remarked that the permanency of a bromide print had many times been questioned, but he was of opinion that if the paper and the gelatine used were pure, and the various operations properly carried out, the bromide print would be as unfading as carbon or platinotype. After describing the care exercised by the Eastman Company in the selection and preparation of their papers, Mr. Smith proceeded to make an enlargement from a quarter-plate to 15×12 by means of one of Eastman's enlarging lanterns, using paraffin as the illuminant; but he explained that lime or electric light was preferable, though not so much within the reach of all. Having successfully developed and fixed the print, the new Kodak camera was shown and explained—the principal advantages over the old one being a larger picture, better lens, and improved shutter.

NOTTINGHAMSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.

DECEMBER 9.—Mr. S. Wells (Vice-President) in the chair.

Mr. F. G. PIERPOINT, of the Leicester Society, gave his lecture entitled *A Trip up the Thames from London to Oxford*, profusely illustrated by slides shown by the limelight. The negatives, 12×16, were taken by him on a pleasure trip, and the slides were reductions from these. All points of interest were noted, viz., Henley, Mortlake, Chillingworth, Reading, Windsor, &c., the lecture being both humorous and instructive.

DARLINGTON PHOTOGRAPHIC SOCIETY.

DECEMBER 9.—Mr. E. Ensor presided.

Mr. P. J. COOPER gave a demonstration of *Making Lantern Slides from Large Negatives*. The apparatus used was Marion's new lantern-slide camera. The slides made were afterwards thrown on the screen by the optical lantern.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

DECEMBER 3.—Mr. R. A. Scott in the chair.

Regarding a proposed Photographic Institute, the Society, in the main, was favourable to the proposal.

Dr. ANDERSON gave a short paper and demonstration of *The Platinotype Hot Bath Process*. Some of the members, however, upheld the claims of bromide of silver paper in preference to platinotype.

Correspondence.

Correspondents should never write on both sides of the paper.

DECEMBER MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—A PORTRAIT OF DAGUERRE.—A FACSIMILE BUST OF THE INVENTOR OF PHOTOGRAPHY OFFERED TO FOREIGN SOCIETIES.—PLATINUM TONING.—A NEW CAMERA.—A SUGGESTION OF THE PRESIDENT.—EIKONOGEN: FORMULA, &c.—M. BALAGNY ON CONTRETYPE.—THE SAME ON THE YELLOW STAIN ON NEGATIVES DEVELOPED WITH HYDROQUINONE.—PUBLICATIONS BY MESSRS. GAUTHIER-VILLARS.—A BANQUET, &c.

The Photographic Society of France held their monthly meeting on Friday evening last, the 6th instant, M. Davanne in the chair.

The President informed the Society that the Directeur des Beaux-Arts had kindly presented to the Society a portrait of Daguerre painted by Carpentier. A vote of acknowledgment was passed.

The Chairman furthermore informed the members that many applications from foreign societies had been received, requesting a copy of the bust of Daguerre in the possession of the Society. He (the Chairman) wished to inform the members that in committee it had been resolved to offer a cast from said bust gratis to any foreign Society making an application for the same. This resolution of the committee was immediately ratified by the Society.

M. Mercier made a very lengthy communication on toning with platinum salts. I find nothing superior than is proposed by Lyonel Clark and others in England. M. Gartine also forwarded a letter upon the same subject.

Messrs. Marillier & Robelet presented a very ingenious little secret camera, which they have christened "Passe-partout." It consists of a

lens placed upon a cone, which serves as the camera, and with the lens is only about three inches high. This cone slides along the double dark slide. Two exposures can be made on each plate, which give four negatives for each slide. The size of negative obtained is about two and a half inches square. It is a very compact little apparatus, and were a roller slide and film adapted it would be the best I have seen.

The President in replying to some member as to formula, made this very wise remark, "That it would be well if every formula proposed to the Society were presented in this wise:—Let the liquid, either water, alcohol, or such-like, be represented by 100, and not as is sometimes written by 30 (the ancient French ounce), which causes confusion."

Several communications were made on eikonogen. M. Vidal submitted to the Society the results of his experiments on this developer *à la mode*. During the discussion he was not of the opinion of M. Andra as regards the solubility of the product. It is proved that its solubility is increased by being dissolved with the carbonate and sulphate of soda or potash, and still increased by being boiled together. M. Vidal then gave a formula compiled by M. de Laniers, with which he (M. Vidal) had obtained excellent negatives:—

Boiling water	600 parts.
Soda sulphite.....	100 "
Potash carbonate	40 "
Eikonogen	20 "

As this formula contains a greater quantity of eikonogen in solution than any other that has been published, M. Vidal calls it "bain intensif," and said that he preferred to develop by the formula given by M. Andra, and to employ the other if he saw that the image did not come up rapidly enough or did not attain sufficient intensity. In answer to some questions, M. Vidal replied that with eikonogen alone an image could be developed by the addition of a little glycerine to the developing solution. M. Vidal continued by saying that it was absolutely necessary to wash the negatives for at least five minutes before fixing or the yellow fog would appear. The fixing solution employed by M. Vidal is composed thus:—

Water	1000 parts.
Hyposulphite of soda	260 "
Bisulphite of soda.....	50 "

From all that was said on eikonogen, it is proved that this developer has a decided advantage over all others. It does not stain the hands, is easy to carry about, does not decompose, makes pure negatives easy to print, &c.

M. Balagny gave last Friday evening a very interesting lecture on how to obtain a negative from a negative. This is how he operates to obtain the desired results:—Plunge, said he, gelatino-bromide of silver, upon whatever surface it may be coated, into a bath of bichromate of potash (three per cent.), and that for five minutes. Drive off the excess of the bichromate solution with a squeegee, and wash, if a glass plate, its back with a sponge. Leave the prepared surface to dry in the dark. Place the negative to be reproduced in the printing frame, and the dried bichromised plate or film just prepared upon it, in the same manner as you would lay sensitised albumenised paper upon a negative. Expose five minutes in sunlight, and from thirty minutes to one hour in the shade. I prefer films because more pressure can be applied in the printing frame than with glass. Take the exposed surface out of the printing frame and wash it until all the bichromate has disappeared. Now place it on the bottom of a tray, the sensitised surface uppermost. Expose it to the light of a gas jet about three feet distant, and for thirty seconds of time. Plunge it into the developing solution, which may be either an old bath of hydroquinone or iron. An old weak bath is preferable. It ought to be completely developed in ten minutes. Wash well, and plunge it into a citric acid solution (four per cent.). Allow it to remain about two minutes. Wash well and fix in

Hyposulphite of soda	200 parts.
Water	1000 "

M. Balagny made a communication on the yellow stain sometimes observed on negatives developed with hydroquinone. His opinion is that it is to be put to the charge of the operator in not washing the negative sufficiently before plunging it into the fixing bath. The best means to avoid such stain is to acidulate the hyposulphite bath with citric acid. Two per cent. of citric acid is sufficient. The cause is that insufficient washing of the plate renders the hyposulphite alkaline, and thus the stain.

The Government has just awarded to M. Balagny the "Palme Académiques." We felicitate M. Balagny on receiving such well-merited honours.

Messrs. Gauthier-Villars & Son, the celebrated photographic publishers, have just turned out of their presses the "sixième fascicule" of M. Ch. Fabre's *encyclopédique Treatise on Photography*. This number bears the title *Phototypes Negatifs* instead of clichés or negatives, thus carrying out the wishes of the late Photographic Congress of Paris.

Another banquet is to take place on the 16th of this month, in honour of the fiftieth anniversary of the discovery of photography, under the auspices of the Chambre Syndicale de la Photographie, and I hope the photographic community and their friends will respond to this invitation, as great progress has been attained, in that a reunion of friends can now be got together, and a banquet got up at a cheap rate, twelve

francs, when formerly the subscription amounted to thirty francs each person, so that only the richer members of each corporation could afford such a sum, and the poorer were prevented, much to their dissatisfaction. They do much better in London, so a gentleman told me from England. He said, "They get up a very nice dinner party for five shillings per head, and all joining makes it very jovial." This ought to be tried in France, as even twelve francs is too high a price for many of the profession.

PROF. E. STREBINO.

196, Rue Legendre, Paris.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—During the past few weeks a considerable number of columns in your JOURNAL have been taken up by a discussion in letters which you are pleased to head "Amateur versus Professional." Why there should be any "versus" in the matter is a thing which I, in common with many others, fail to see. We hear nothing of "amateur versus professional" in the literary world, nor do we in journalism, and probably some of the most pronounced advocates of "separatism" would be the first to see the absurdity of the situation if you were to take it into your head to distinguish between those of your contributors who write because it is their business to write, and those who write simply because they have something which they think of value to communicate. I am happy to think that the possibility is not likely to occur of such a foot-note to an article as:—"We are quite aware that the views expressed by the writer of this article will not bear investigation; but as he is obliged to earn his living by writing, we are compelled to give his communication precedence over several valuable papers from amateurs."—ED. B. J. or P.

What would some of your correspondents think, too, of a Royal Academy Exhibition with the works divided into amateur and professional classes?

I am a professional photographer; but I am not blind to the fact that it is just that my work should be judged, not by what I profess, but by what I perform, and if others, be they professionals or amateurs, can do my work in a more satisfactory manner, either with regard to quality or terms, than I can, it is my duty to seek another occupation where my services will be of more benefit to the community, and not to waste my energy in a vain attempt to establish a system of "protection" which would be as immoral as it is impolitic.

There is another phase of the question, bearing upon the attitude of some amateurs towards professionals, upon which I should like to say a few words; but as I have already extended my letter to some length, I will ask your indulgence at a future time,—I am, yours, &c.,

B. K. BEXCHINO.

To the Editor.

SIR,—The discussion anent the question of amateurs dabbling in professionalism does not seem to me to have advanced the subject much: one suggestion, viz., the introduction of the term "gentleman amateur," ought to be at once vetoed as being decidedly objectionable—we are all gentlemen, or, at any rate, ought to be. My own experience points to the fact that the encroachments of the amateur on the preserves of the professional are nearly all due to the ignorance (in many cases) and shortsightedness of the latter. There is no doubt whatever that this large body of amateurs means increased trade all round, and the sensible professional should have been "in the swim," ready to avail himself of the many requirements of amateurs, such as retouching, enlarging, &c.

I have heard very strong expressions, in my part of the country, used by professionals as against their amateur brethren, every one of whom with common sense might have benefited himself by cultivating their acquaintance.

In my capacity of photographic chemical dealer I have mixed with "all sorts and conditions of amateurs," and have become acquainted with their peculiarities, their wants, and their idiosyncrasies. Some of them, I must admit, are very objectionable: bad manners, total apparent ignorance of the value of one's time, &c., have all been my experience; but it's an "ill wind that blows no good," and I have generally contrived to get the best of it. Early in my experience I found it necessary to undertake work for amateurs, such as printing, developing, toning, enlarging, and the like; and I was able to put a considerable amount of business in the way of the profession, or rather two young members of it, one of whom is now firmly established and independent of any assistance from me; the other, who was very glad of my work at one time, is now also getting rather independent, consequently I am obliged to look further afield; and this brings me to what I was wishful to say as to amateurs dabbling in professionalism.

My little experience related above refers to the demand for certain work and the difficulty of supply; and I confess at once that I have availed myself lately of the assistance of one or two competent amateurs with time at their disposal, who have, by doing work for me, enlarged and improved their stock of apparatus, and kept themselves well supplied with plates and chemicals. An instance will suffice: A gentleman about to give a lecture requires a set of slides made from drawings or book illustrations; he comes to me and gets a price, which, by the way, he thinks "high;" he tries the local photographers without avail, as they evidently will not, or more likely, cannot undertake the work. He eventually returns to me, and is prepared to pay the price asked. I call

in the aid of my amateur acquaintance, the result being that in rather less than the stipulated time I am able to hand over the slides carefully and neatly copied and mounted, with satisfaction to all concerned. My amateur friend likes the work, for which he receives fair—in fact, liberal value. Another result follows, which is frequent applications of the same nature—all of which work, as I said before, might be done by the professional photographer.

At the present time I am acquainted with several amateurs who make fairly good business with their knowledge and skill, this business being, as a matter of fact, forced upon them on account of the shortsightedness of professionalism. One of them has the finest and largest collection of "lake views" I have ever seen; another has an almost unique collection of photographs of antiquarian interest; another is great on lantern slides; and yet one more (a labourer in a factory at a pound a-week) makes enough out of bromide enlargements, done principally on Saturday afternoons, to keep himself and family during the rest of the week. I may say that I should not employ the amateur in this manner if I could see my way elsewhere; but the demand exists, and there's no alternative. I consider these gentlemen, all getting their livelihood at the desk or in other ways, clearly entitled to the designation of amateur; and I come to the conclusion that in their dealings with amateurs, as a rule, the large body of professionals have acted unwisely—they have missed a great deal of information for one thing, and for another the making of interesting and profitable acquaintance. Personally, I have always found the greatest pleasure and profit in the society of amateurs; I have on occasions lent them my dark room, and paid them other attentions, and am the recipient of numerous cordial invitations from various parts of England, Scotland, and Ireland, offering me the like facilities. Much more might be said on this point.

In conclusion, I must not forget to say that, although there are, I know, business firms who advertise and undertake professional enlarging, printing and the like, there is in every town a local element averse to entrusting their negatives to post or rail, to say nothing of the expense, and who prefer their work done on the spot, wherever possible, and it is of these I write and for whom I cater.—I am, yours, &c.,

A PHOTOGRAPHIC CHEMIST.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—It is a significant fact that of the many hundreds of persons who saw the collection of Mr. H. P. Robinson's photographs, lately on view at the Rooms of the Camera Club, only one person (and he had not the courage to sign his name to his letter) took exception to my letter, and he did not pretend to dispute the accuracy of my statements. Mr. William Durrant, it is true, has taken up the cudgels on his friend Mr. Robinson's behalf simply because they are friends of many years standing. He makes no attempt to disprove the justice of my criticism of his friend's work, but objects to it because I am unknown to fame, either as a photographer or an art critic. What has that to do with the question? Now that he knows the collection has been removed, and that therefore it is impossible for me to do so, he asks me to "particularise." I think this answers his letter. If Mr. Durrant cannot see the fault of his friend's works when they are pointed out to him, it may be as well to let him continue to admire them. I had, and have, no intention of carrying on a discussion, or of attempting to educate a professional photographer. My object was simply to express my views for the benefit and guidance of such amateurs, who, though liable to be misled by Mr. Robinson's clever photography, had yet common sense enough to recognise, when it was pointed out to them, the lack of art qualities in the patchwork photographs (clever as they are) for which he claims that they are works of art. I can imagine a combination printer deriving from his work the same kind of satisfaction that a boy might do who cleverly pieced together the parts of a puzzle map; but I cannot conceive it possible that he could experience in it any of the pleasure that an artist feels in the painting of a picture. Medals have been awarded to Mr. Robinson (and justly) for his clever photography; but I have yet to learn that they were awarded to his photographs as works of art.—I am, yours, &c.,

BART. ROUS.

The Arts Club.

To the Editor.

SIR,—I think it will throw some light on the fuzzy and sharp controversy if we consider for what purpose the photograph is taken. It may be either descriptive or artistic. Most are descriptive, and as a describer the camera has no equal. For this end sharpness is a benefit—indeed, there cannot be too much of it.

Description is so much the stronger side that a doubt crosses one's mind whether pictures had not better be left to the hand. You don't see a dozen photographs in a year that please you to look at as works of art. One great reason for this is that you can leave out nothing on the plate. You have no power of selection; you can hardly find a subject that is not spoiled by a lamp-post, a cast-iron railing, a corrugated iron roof, or a brand new dissenting chapel in the Gothic style. But if you persist in picture making it is best not to be too defined. You must, to be successful, have "atmosphere." People have looked at so many paintings that are not sharp that they have got to associate fuzziness with artistic work. The

foreground should be rather better focus than the back, but I think the difference should not be too great. Shun f-64.—I am, yours, &c., Q.

FLASH-LIGHT PHOTOGRAPHY.

To the Editor.

Sir,—Just a caution to those about to use the above. If using a pneumatic arrangement be careful to have plenty of tube; I have lately escaped a bad accident through not taking proper care. I had arranged to fire three lamps to photograph a stage group, and not having enough tube the first lamp was too near; without thinking, I was almost over it when firing, and had part of my eyebrows singed off, a scorched nose, &c. The light is a good thing but requires care.—I am, yours, &c.,

110, High-street, Watford, December 10, 1889.

FRED. DOWNEN.

A TRADE UNION.

To the Editor.

Sir,—In your last week's issue is a letter from Mr. A. G. Field, in which he refers to an article in your valuable ALMANAC just published. This is an elaborate scheme for a photographers' trade union, the Council of which is to say who is and who is not to work for whom, to fix the rate of wages, hours of employment, conditions for strikes, &c. In fact, it is to regulate the photographer's business, and to taboo it and him, as I read it, unless he complies with its demands.

It seems to me considerate of Mr. Field to postpone the actual realisation of this scheme until next summer, as it will give time for many traders to meet the conditions intended to be imposed upon them. It may, in fact, by that time appear to some of them that they can altogether dispense with male assistants, for I, in my simplicity as an amateur, have an impression that with one good head of a master to direct, photographic work might, at a pinch, be well done by women only, with six months' notice to train efficient retouchers. I hope provision may be made for the effects of what many will look upon as a project for a trade tyranny, and amongst them—I am, yours, &c.,

Melton, December 7, 1889.

AN AMATEUR.

Answers to Correspondents.

J. F. BLACKWOOD (Taunton).—1. Apply to the Platinotype Company, Southampton-row. 2. The address is 50, Gray's Inn-road, London.

PHOTO (Norwich).—When a superficial layer of iodide or bromide of silver is formed on the surface of a collodionised plate, and such can be wiped off, it indicates that the bath is too weak.

J. WILLIAMS.—Make the prints by contact on bromide paper. By this method brilliant prints may be obtained from a negative which is too feeble to yield anything presentable on albumen paper.

W. W.—The Art Union picture, *Stolen by Gipsies*, is copyright. A penalty would be incurred by making lantern slides from it—10s. for each copy. The same applies to the pictures, *The Ruling Passion* and *For the Safety of the Public*.

A. FARLEY.—If the back combination of the portrait lens consists only of a single glass the instrument is certainly imperfect. As, from the description, it is only a common form of French lens, it would, in all probability, cost more to replace the missing lens than to purchase a complete combination.

W. P. ADAMS.—1. For information on these subjects you had better write to the Secretary of the Royal Astronomical Society.—2. Messrs. Frith & Son, Reigate, or Messrs. Poulton, Lee, may probably be able to supply the views required. If they cannot they will possibly say where they are to be obtained.

W. WIER.—Beyond what has been published and what appears in the specification of the patent we know nothing of the process. We are not in the secrets of the Company—and we know they have some—so cannot say whether or not they work strictly according to the specification. May not your failures be due to want of experience?

W. G. (Stralbrooke).—The front, or back, combination of your lens will work quite well as a landscape lens. For such small plates as you employ you may turn the convex surface of the lens next to the view, by which a larger diaphragm may be employed than when the concave surface is outside. But make a few trials for yourself, and then determine upon which alteration will prove most serviceable.

S. G. BIGGS.—The negatives are all under-exposed, and very much so, too. Although you may be working exactly the same as you have been doing for months past, it must be remembered the light is not the same as it was two or three months back. To take instantaneous pictures in December, a large stop must be used and the shutter must not work very rapidly, otherwise under-exposed pictures will be the result.

MORE LIGHT.—As the Corporation are prepared to supply the electric light, you cannot do better than consult their engineer. He will advise you as to the best method of applying it in the studio. One light, but it must be a good one, will be sufficient, and it can be arranged to be used at each end of the studio, also for enlarging with. In this case the lamp must be what is known as a "focus-keeping" one, so that the arc is always retained in the axis of the condensers. But there will be no difficulty about this. The necessary lamps will, doubtless, be supplied by the Corporation. No work is published on the subject, but several articles upon it have appeared in back volumes.

A. Z.—Clearly you do not realise what is essential in a lantern slide. It is no wonder that the pictures look "dark and muddy" on the screen, if the two sent are a fair sample of your work. In a good slide the highest lights are represented by bare glass, in yours they are fogged and stained. Instead of using ordinary plates, we advise you to get some specially sold for transparencies, and then to use the developer recommended for them by the makers.

BETA asks the following question: "If I put up a studio in my garden, and have it in use for seven years, can my next-door neighbour extend his premises in such a way as to obstruct the light to my studio without recompensing me for the injury?"—The neighbour can put up anything he likes on his own ground without let or hindrance under the present circumstances. Had the studio been in existence twenty years the case would then be different, as then Beta could claim "ancient lights." Twenty years' uninterrupted use is necessary in order to claim this privilege.

AQUA PURA writes: "Taxing chemicals would, I think, injure the professional as well as the amateur. In our town (Blackpool) a professional photographer has to pay a special water rate of 1s. per year; if this is the same in every town, I am sure if they who call themselves amateurs (but are really not, because they sell their work) were charged a special water rate, it would be one way of clearing off what a well-known weekly paper has rightly named as mongrels, and so give the professional a chance to make a living, and the amateur a chance to dabble in the art for amusement, or to make a study for the advancement of it."

WEAK NEGATIVE asks how a negative which has been varnished can have the varnish removed so that it can be intensified. He says he has poured methylated spirit over the plate, "but the varnish does not wash off."—Supposing the menstruum of the varnish was alcohol, methylated spirit will redissolve it; but it will be necessary to soak the plate in the spirit for some time, and in some cases to make the spirit warm when it is applied. Gentle friction with a pledget of cotton-wool will also assist in the removal. When the varnish has dissolved it is necessary to rinse the plates with two or three lots of fresh spirit before proceeding with the intensification.

SPOTS writes as follows: "Some time back I sent for your opinion of the spots as on the enclosed prints. You said you should think it was dust or some of the kind settling on the paper after sensitising, but I cannot trace it to this, as I have taken every possible means of avoiding anything of the kind settling on it. The method I treat the paper is as follows:—After taking it off the bath it is laid between two sheets of blotting paper, the paper being rubbed over to avoid the albumen paper drying in tears, and it remains there generally till nearly dry, and then is finished off by heat. I have used the same mode of working for a long time, and have not had these spots appear till a recent date. I tried clean blotting paper, but without any good result. Perhaps you could form some other opinion as to what they are, and let me know at an early date, for I am anxious to find out what they are, as I have to destroy a number of prints daily through it. A slight trace of them can be seen in the printing, but they seem to come out much more distinct when the paper gets wet. I have wondered if anything connected with the platinotype printing would cause it, as they are both done, filled in, and printed in the same place."—From what our correspondent now says we cannot well see how the spots can be due to floating particles settling on the paper while drying. We can now only suggest that the blotting paper may be at fault. Our correspondent says he has tried using some clean sheets, but we would suggest changing the sample altogether. It is clear that if the blotting paper contains deleterious matters—and many kinds do—the spots may easily be accounted for. As the spots show in the printing they must either be due to the paper itself or something in connexion with the sensitising or drying.

THE business of Messrs. Horace C. Lewis & Co., of 29, Ranelagh-street, Liverpool, has been formed into a Limited Liability Company.

PHOTOGRAPHIC CLUB.—The annual dinner will be held on Wednesday, the 18th instant, at Anderson's Hotel. On this occasion a testimonial will be presented to Mr. E. Dunmore, the retiring Hon. Secretary and Treasurer.

THE new Catalogue of Mr. John J. Atkinson, Liverpool, contains a copious list of the lenses by most of the eminent opticians, together with cameras, stands, head rests, printing frames and material; in short, everything a photographer can desire. It is well illustrated and contains 180 pages.

MR. W. KAY, Science School, Kidderminster, writes that the arrangements for the Exhibition are progressing favourably, and from the number of entries made there is every probability of a good collection of pictures being got together. Any information required by intending exhibitors will be promptly attended to by writing to the Hon. Secretary.

MR. F. A. BRIDGE sends us a cabinet group of the four eminent violinists who form the quartette at the Monday Popular Concerts, St. James's Hall. The group was taken on a dark, foggy November afternoon, by the agency of four of Hart's magnesium flash lamps with a lens working at f-6. The likenesses are unmistakable. The party are taken *in situ* on the platform.

No. 1546. VOL. XXXVI.—DECEMBER 20, 1889.

TESTING DEVELOPERS.

THERE is ample room at the present time for a full and accurate comparison of the different rival developers now in use or competing for patronage. It cannot strictly be said that we are entirely without published information of the nature alluded to; the trouble is rather that there have been so many utterly antagonistic views expressed of one and another developer that any reader not versed in photographic matters might well be excused for doubting the combined capability of the writers as accurate experimentalists.

The fact is, however, that we have no recognised standard of comparison either for developers or for sensitive films, and that, consequently, every individual who may lend himself to the somewhat thankless task of conducting a series of comparative trials between different developing solutions must not only establish his own standard of efficiency, but must trust almost entirely to his own judgment in matters of detail. This being so, it is almost a matter of necessity that given, say, half a dozen fully competent and equally accurate workers, the results of their individual trials would be as many totally conflicting reports. But when the published accounts come chiefly from those who recognise no standard beyond their own convenience and fancy, it is inevitable that some considerable variety should appear.

We can scarcely particularise, but instances are not wanting; indeed, scarcely a week's issue of the JOURNAL passes without the report of some discussion in which the most opposite opinions are expressed by different speakers with regard, say, to the comparative merits of hydroquinone and pyro, or of eikonogen and everything else. But, as a rule, no very definite data are supplied as to how the conclusions were arrived at, so that one can but regret, too frequently, that space has been occupied in the reporting.

How matters are to be improved it is not easy to say in an off-hand manner. The every-day photographer will, no doubt, be inclined to think and to assert that the practical experience of every-day workers is all that he cares about, and that merely scientific results are altogether beyond his requirements. Well and good, so far as it goes, if the "practical results" are based on a solid foundation so far as theory is concerned; but there is just where the scientific photographer will differ. The "practical" conditions are not stated with sufficient definiteness to render them of much value from his point of view.

There are, in fact, two entirely distinct phases of the question, each of which deserves very close consideration, and it is extremely difficult to say which is really the more important. We have, first of all, the purely chemical or scientific side, under which we consider developing agents simply

in relation to their comparative reducing power. But the strongest reducing agent is not necessarily the best developer. The mere reducing power of the solution upon bromide or other haloids of silver in the absence of foreign matter can easily be estimated with mathematical accuracy, but the case is entirely altered when the numerous complications of a sensitive photographic film are drawn into consideration.

It is easy for the chemist to pronounce that pyro, hydroquinone, or eikonogen, as the case may be, is the most energetic developer; but the photographer is interested only in which is the *best*, that is to say, which is the best under the greatest variety of circumstances. How is the problem to be solved? and upon what lines ought we to proceed in attempting to establish a standard system of comparison?

Some years ago Captain Abney published the results of a series of experiments conducted with a view of determining the reducing power of pyrogallie acid upon bromide of silver. In these, weighed quantities of silver bromide were submitted to the action of pyro in solutions of definite strength in combination with definite quantities of alkali; and by quantitative analysis of both the reduced and unreduced silver the power of each grain of pyro was accurately gauged. But even here we have not all we should like to know. How much, for instance, does the reducing power increase with increase of alkali? How does time affect the operation? and temperature? How, in fact, do the conditions which chiefly rule the development of a sensitive film affect the plain bromide? Here alone there is a large field for investigation.

But when we turn to the photographic film in which the character of the silver salt is altogether altered or masked by its organic surroundings, whether gelatine or collodion, as well as by action of light, it is not difficult to imagine an entirely new class of circumstances, in which the first valuation of the mere reducing agent is of comparatively little use.

Whatever results may be arrived at in connexion with pyro, they can scarcely be accepted as having much bearing upon the possible behaviour of either hydroquinone or eikonogen, except so far as regards mere reducing power. These latter newer developers are known to be far more powerfully modified in their action by foreign matter than pyro, and, consequently, cannot be judged under the same trials. In fact, it seems almost impossible to establish any universal system of comparison except as mere reducing agents.

Something may, at least, be done to clear the way in this direction by arriving at a definite knowledge of the absolute reducing power of each of the substances named upon silver bromide. For instance, having found what weight of silver bromide one grain of pyro *plus* a given quantity of alkali will

reduce, it will be comparatively easy to follow on by ascertaining what strength of hydroquinone or eikonogen, or what combination of these agents with alkali, will produce a like result. So much being gained, it will be possible to compare them as *reducing agents*.

Next, it will be desirable to compare the retarding or restraining effect, if any, of soluble bromides, sulphites, and similar additions to the developer when used with the three agents respectively upon plain bromide of silver in the absence of any surrounding film of gelatine or collodion; and, finally, to test the relative effect of such organic complications on the reducing action of the developer.

The mere quantitative analysis of the results of such experiments is simple enough to any one with a comparatively slight acquaintance with chemical manipulations, but to arrive at any useful result must necessarily involve a very extended series of trials: and then the verge of the real question of the "best developer" is barely reached, for from a practical point of view the difficulties and complications are so wonderfully multiplied that we are compelled to repeat, it seems almost impossible to arrive at a definite and useful comparison.

Meanwhile, until some such work has been gone through it would be well to refrain from speaking of any developer as being "the best" under all or even under any circumstances.

NEGLECTED PROCESSES.—WHY ARE THEY NEGLECTED?

In a number of articles which have appeared in these columns of late, we have directed attention to several disused processes which are capable of yielding excellent results, in some, such as are not to be equalled by other methods. In this series no allusion has been made to some which have become obsolete on account of being superseded by others, by which the same or similar results may be obtained by better or simpler means; nor has it been intended to include every means by which excellent photographs can be produced, though not at present used.

There are many systems—and useful ones, too—which come under the title of the iron processes, as well as other interesting ones of Herschel, Hunt, and other workers. These, by which a great variety of colours may be obtained, are well worth the attention of experimentalists, though they have seldom been alluded to of late years, with the exception of the ferro-prussiate and the platinotype, both of which are iron processes. An ardent experimentalist in these very early methods was Mr. Michael Hannaford, who, over a quarter of a century ago, produced excellent prints by several of them, and described the methods he adopted before the late South London Photographic Society, to whom he presented his examples. These are, we presume, now in the possession of the Photographic Club, as at its demise the Society's archives were presented to the Club. These pictures are now exceedingly valuable as proving the permanence, or otherwise, of the processes themselves, or of the modifications of Mr. Hannaford. A description of most of these interesting, if not really valuable, processes will be found in many of the older works of photography—for instance, Hunt's *Researches on Light* and the various editions of his *Treatise on Photography*, from 1841 onwards—under the heads of cyanotype, chrysotype, amphitype, chromatype, ferrotype, catalysotype, &c. An article on the iron printing processes, with modern modifications, also appears in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1889.

Many who have read the articles on neglected processes have, not unnaturally, speculated as to why, if they really possessed the advantages claimed for them, they have become neglected ones. The question is not an easy one to answer, for there may be, and probably are, several reasons why some, at least, of them are not at present in use. One reason undoubtedly is that photographers are somewhat conservative, and slow to leave old methods with which they are familiar for new ones which they will have to learn, even if the new ones would prove advantageous in the end, particularly when the new departure is a wide one. Notably is this the case with some processes, such as the chromotype of Lambert, the powder, and the stannotype process. In all these the whole system of photographic printing is altered. The materials are unlike those in daily use, and the systems are based upon an entirely different principle from that of silver printing. Hence, comparatively few photographers could, or did, devote sufficient time and attention to the subject to acquire the necessary proficiency to work the processes with uniformity and certainty—so essential for working on a commercial scale.

In some processes there was but a slight departure from the ordinary methods with which operators were perfectly familiar. The eburneum and the photo-crayon were essentially wet collodion processes, and why they were not more generally practised, considering the excellence of the results, it is certainly difficult to imagine. The albumen process, again; this is very similar in principle to the wet collodion, yet in England it has been but little practised, though, until the introduction of specially prepared gelatine plates, it was, without doubt, far and away the best method of making transparencies, either for the stereoscope or the lantern. It is true here, too, that considerable skill, which could only be acquired by practice, was requisite to obtain pictures such as those produced by Ferrier and others on the Continent, and few here gave sufficient attention to the matter to acquire that necessary proficiency.

A reason why processes which were undoubtedly good ones and exceedingly valuable were not at once adopted, is that they were introduced at the wrong period, *i.e.*, before their time. Notably was this the case with some of the photo-mechanical processes. For example: The late Mr. Fox Talbot more than thirty years ago produced engraved copper (intaglio) plates by an etching method analogous to, if not identical with, those now so largely employed commercially, and, what is more, Talbot's work was in no way inferior to that now produced. Paul Preterre again, he about the same period produced intaglio plates and relief blocks in half-tone by methods very similar to those now employed; but these processes, like that of Talbot, did not succeed commercially, as the time was not then ripe for them. The same remark may be applied to photolithography. As far back as 1865 Messrs. Bullock Brothers produced photo-lithographs in half-tone which were quite as good as most of the commercial work issued at the present time, yet the process, good as it undoubtedly was, remained in abeyance as a neglected one for many years.

The chief object of the recent articles has been to direct attention to good and useful processes which are not being employed, and some of which might possibly meet with better practical success if they were reintroduced at another time or under different conditions, as witness the instances just quoted.

Already our articles would appear to be bearing fruit. It will be remembered that in our number for the 22nd ultimo we, when referring to methods of making negatives direct

From negatives, gave a brief outline of Mr. Thomas Bolas's method, published in 1880. As will be seen by our last issue, this system was introduced and described as a novelty at the last meeting of the Photographic Society of France. The process, and the method of working it, is precisely the same as that published nine years ago by Mr. Bolas, since which time it has remained in abeyance, now to be resuscitated.

SOME years ago considerable interest was caused by the exhibition of photographs of frosted window panes, subjects which for fairy-like delicacy and beautiful variety of form it would be difficult to surpass. These pictures—for such name, indeed, they deserve—are most easy of production, and can be made to subserve a variety of useful and ornamental purposes. We have seen them used in Christmas cards, and we know of an instance where a very pretty example was utilised by a pattern designer as the basis of ornamentation for a damask table cloth. We have not seen panes of glass specially arranged for the purpose of receiving the fairy tracery, though it would be easy to fit up a box with glass cover for the purpose; usually the negative has been taken when an unusually pretty frost picture has arrested the attention. The advantage of a method extemporised for the purpose would be that a dark-coloured glass could be used, or even a sheet of ordinary colourless glass backed with a piece of black cloth, which would avoid the only difficulty attending the photographing of such subjects—that of obtaining a dark background where the window pane is awkwardly situated.

FROST pictures are, however, by no means the only beautiful figures drawn in nature's own laboratory, and in the Arts and Crafts Exhibition were exhibited some most singular and beautiful pictures obtained by the vibrations of the human voice upon a semi-fluid paste, spread on an elastic membrane stretched over the mouth of a receiver. A single note, sung steadily and accurately, throws the membrane into waves and curves, which are then immediately photographed. Mrs. Watts, the exhibitor, terms these pictures waves, lines, flowers, trees, ferns, and the effect in transparencies is singularly beautiful. In the "daisy" forms it is stated that the number of petals can be made greater or less by altering the pitch of the note; the higher the note the greater the number of petals. To the practical photographer numerous modes of varying these effects will readily present themselves.

ONE of the most effective cloud scenes we remember to have seen is engraved in *La Nature* of a fortnight ago. It is copied from a photograph taken by M. Jules Jarden in July last, the time chosen being a quarter of an hour after the ascent of a balloon, which occupies the middle of the picture, backed by beautiful examples of cumulus clouds. The writer quotes the description given in *Annales de Science, &c., de Genere* for obtaining successful cloud views. "The blue light of the sky exercising a photographic action almost equal to that of the white reflected from the clouds, it is very difficult to obtain a sharp image of the latter. It can, however, be managed by interposing a Nicol prism in the path of the rays, which is very easy, where they enter the camera after reflection from a black glass mirror suitably placed. The polarised light of the blue can thus be almost completely extinguished, while the natural light of the cloud becomes much more intense. The same result can be obtained by reflecting the image from a sheet of water, as Dr. Burckhardt has observed."

IN an article in *Nature*, over the signature A. M. Clarke, the advantage of photography over eye observations is briefly and succinctly described. She is writing about double stars, and, after showing how, owing to no want of skill in the observers, but simply to the deficiencies both in quantity and quality of the materials at their command, existing data lack a desirable precision, she says:—"This at least is abolished by photography; which has, however, as yet proved applicable only to a limited class of coupled stars. With the

extension of its powers to all, a new era in the knowledge of stellar revolutions may be expected to open.

To speak of revolutions naturally causes the mind to turn in the direction of Brazil, and, according to a leading London paper, the last documents signed by the deposed sovereign Dom Pedro were the diplomas raising to the grade of officers of the Order of the Rose of Brazil several European astronomers, the fame of whose photographic work in particular is spread over the whole civilised world:—Admiral Monchez, M. Janssen, M. Perrotin; while diplomas of knighthood in the Order were given to Mons. Paul and Prosper Henry, and M. Frassenet.

News as late as December the seventh has arrived from Loanda, whither the American and European astronomers are converging, with the purpose of observing and photographing the eclipse of the sun. The Europeans are quickly arriving, Mr. Taylor, of the Royal Astronomical Society, London, being among the first arrivals. Cape Ledo turns out to be a very desirable spot, as the meteorological conditions are likely to be better, and their vessel, the *Pinsacola*, can be used as a dwelling-place; the health of the parties is thus ensured. The eclipse is several seconds longer there than at Maxima, and the chances of clear afternoon skies seem to be rather better. The account very grimly concludes:—"If nothing is heard from the expedition the next few days, it may either be taken that the eclipse expedition is finally located at Cape Ledo, or that the semi-cannibal Quicimas have cleared out the whole expedition."

ON THINGS IN GENERAL.

NO one can doubt the immense impetus given to lantern work by the introduction of dry plates, and during the present season it seems to have arrived at a most exalted pitch,—lantern plates, lantern exhibitions, slide competitions, novelties in mounting, and a multitude of other lantern details taking us by storm. And the truth is, a really good lantern slide is *sui generis*; it is the nearest approach to the days of stereoscopic transparencies. Ah! who that can date back so far does not remember the exquisite productions with the label "Ferrier et Soulier" beneath, the perfection of photography on glass, of mounting, and of backing, the translucency of which, whether of surfaced glass or of matt varnish, surpassed everything of the kind. He must be a good worker who nowadays, with every convenience at hand ready-made, can equal, not to say surpass, those beautiful productions. It is surprising that the ease with which a transparency is now produced has not led to a resuscitation of stereoscopic work, if only to enable this kind of slide to be made; but it is to be feared that stereoscopic photography is dead—really dead. Among other causes, retouching has helped, if not to kill, at any rate, to keep it in its grave; for no retouched photographic portrait would be presentable in a stereoscope, the inevitable difference in the retouching of the two sides of the slide would destroy the effect aimed at. But for lantern work there is still a good future, and interesting, fascinating work for the photographer who takes it up. All the readers of this JOURNAL would be interested in the remarks of Mr. Lewis Wright and Mr. G. R. Baker on the use of electric light in optical lanterns; and, it may be said, referring to the point raised, that where a suitable current is obtainable, the adoption of electric illumination may fairly be looked upon as a question of time only since the introduction of the lamp described by Mr. Lewis Wright. On a large scale, and for large projections, the arc light is naturally the most brilliant; but where, by simply turning on the current, with a suitable resistance, light can be obtained in a lamp and fixtures costing under a sovereign, and requiring no adjusting, and it being constantly in the right position as regards centring when once "set," the cumbersome of bag, and the possible danger of cylinders, will be things of the past at no distant period. It is well for attention to have been drawn to the fact that the electric light is by no means so devoid of heat as is commonly assumed; but Mr. Wright very properly points out that the heat it gives is derived from radiation, and not from heated gases, the product of combustion. Now, I am perfectly certain that the amount of heat radiated from the thread of carbon, elongated, it

is true, but of a most trivial superficial area, is decidedly below that emitted from the illuminated spot of lime of larger area in an oxygen-hydrogen light, and when it is remembered that with lime we have, in popular phraseology, the convected heat from the products of combustion added to its radiated heat, it needs no conjurer to determine where the greatest difficulty in keeping the apparatus cool will lie.

It was interesting to note the remarks of an expert when Mr. Dawson, of the Typographic Etching Company, stated that for their kind of work the use of a yellow screen did not seriously injure definition. It can be readily imagined that any possible injurious action from the use of a screen would depend upon two factors—the characteristics of the subject to be photographed, and the nature of the screen itself. Naturally, the use of an optically worked sheet of plane glass would not distort the image, but the reflections caused by the two surfaces of the glass might become very injurious under some easily imagined conditions. The extent, however, to which a carefully prepared selected film of gelatine will interfere with definition is surprisingly slight, and any one desiring to experiment with orthochromatic plates need not hesitate to use such screens for the most delicate class of work; few instances would occur in which he would be able to make any impairment of the finest detail.

I do not think that the usual practical character of Mr. Warnerke's suggestions was seen in his recommendation to use a lamp with coloured screen for illuminating the subject rather than daylight and a lens screen. If the picture were of any large dimensions, equality of illumination from a single lamp or a pair would be impossible, except with greatly protracted exposure, owing to the distance at which the light would need to be placed.

Mr. Cowan's suggestion at the London and Provincial Photographic Association, that the gum used in working in colours upon a carbon print on opal might be the cause of a portion of a certain film having come away when washed under a tap, is no figment, for I have seen a picture in which large portions of the film had, without any interposition of water, peeled entirely away from the support, owing to the action of the gum, though in this case it was in the darkest tones of the picture that the effect had occurred. It is well to draw the attention of the inexperienced to this possibility, for it is so easy to get effects with gum that are more legitimately obtained by other means.

In "Foreign Notes and News" (November 22) I observe a suggestion for the use of rhodium in combination with gold (in the proportion, about, of four to one) as a toning ingredient. I see no reason why it should not be useful, and as it is only about fifty per cent. dearer than gold, no great additional cost would accompany the experiment. Platinum has its advocates, and it may be that rhodium will exhibit some point of excellence: at present gold "holds the field."

When a professional photographer of the eminence of Mr. Groves writes on the subject of a real grievance, his words deserve attention. There cannot be two opinions upon the fact that his letter points to a crying evil—an evil, unfortunately, that it is far more easy to indicate than to describe a cause for. That there are jealousies in all trades and professions goes without saying; but photographers experience its effects with the greatest force, and to such an extent as to make any one despair of concerted action. Again, no line can be drawn to separate the first class from the second, the second from the third, and so on, down to the hundredth degree; and those jackals who thrive upon profits obtained only by cutting prices are the very men who would cut in and announce unlimited re-sittings, or even no pay unless proofs please. Notwithstanding the pessimistic view I express, I should be heartily pleased to see some action started to put an end to a system that is at once costly, wasteful of time, and vexatious in the highest degree. FREE LANCE.

COLOURED PHOTOGRAPHS.

XVI.

In our last paper we completed, I hope successfully, our *first painting* of a portrait. I think also that, sensibly thought out, it may be conceded that what we did in the case of a *legitimate sketch* we could also do if set to work upon a *photographic base*. Thus far then we

may be considered to have produced a work of art. We can now take up our sketch or photograph and proceed with our second painting.

We may commence our second painting by working in the shadow on the forehead with Indian red, being careful at same time to adhere strictly to the natural form. Then we must put in the dark shadow formed by the socket of the eye with a suitable shadow tint, such as may be made by a judicious mixture or blending of Indian red and cobalt. On the extreme edges of all these shadows we will find it advisable to work with a little pure cobalt, being most careful to accurately preserve the strict form of the shadows. The edge of the upper eyelid we may mark in with Indian red.

We may regard it as a general rule, that we must represent the edges of all shadows with a grey. It is not a fancy that dictates this rule, but nature herself. If we have any doubts on this point we can very easily put our minds at rest. Let us place a pencil or other article on a sheet of white paper and I am certain you will have no difficulty in remarking the grey edge which will bound the dark shadow. By artificial light this peculiar grey edge is not quite so perceptible, but by daylight it is palpable to a degree.

The next point in our work is to paint in the colour on the cheeks, this we do with a tint composed of pink madder and a little vermillion. We must be careful in doing this to preserve with truthfulness the various gradations of colour, and light as well, on the cheek bones. Stipple the edges of this colour as you approach the nose, and also spread the colour well up to the temple. Diffuse the colour well over the cheek towards the ear, and put a little on the chin as well. It will be found now that many of the shadows will not appear as deep as they did before we started this work; we must now deepen these extreme shadows until they have regained their natural and necessary depth and power.

It will be found advisable now to hatch over the shaded portion of the forehead with blue or a bluish grey. This grey must become bluer as it approaches the extreme or retiring edge. Sometimes it will be found necessary to carry this bluish grey down the nose, and where it appears so, do not hesitate to do it. The mere fact that the shading of the forehead was carried out by placing the red shades first, and the blue or grey second, may not have struck the reader as a matter of any importance. But it is, on the contrary, a most important fact, and necessary to the production of a really good work. It may seem a matter of indifference whether we start with red and finish with blue, or start with blue and finish with red; but such is not the case, and the reasons are obvious if we only think for a moment over it. It will be found in practice, if we place the red shadows *first*, the application of the blue afterwards will result in a bright and clean effect; whereas, if we reverse the application of the tints, that is, place the blues first and then the reds in the second place, the result will be dirty and thoroughly unworthy of being classed as artistic work. If you desire to study a glorious example, look up the works of Rubens, and you will see that he works in accordance with these principles.

We can next work a cool green over the socket of the eye, the best method of applying the colour being to *stipple* it on rather than to hatch it. A good tint for this purpose may be made from a judicious mixture of cobalt and Indian yellow. The shadow at the edge of the lower jaw should have blue worked over it, and care should be taken to observe the true form and depth of tint. It will be found necessary to paint in the bluish shadows on the temples. Make it a rule to soften the edges of all shadows, no matter where found, by stippling upon them.

It will be found, as we progress with our work, that some, if not a number, of white spots seem to have been left. Need I say these must be filled, and with their proper colour? If we do not pay attention as we go along, these white spots will appear in anything but pleasant numbers. We should therefore look out for them from time to time as our work goes ahead, and then fill them up. It sometimes happens that the hatching has a rather unpleasant appearance, looking, if I may so put it, somewhat wiry. This is an unfortunate effect, but we can remedy it by washing it several times with a clean brush dipped in water. This treatment will tend to blend the colours and produce softness. Another effect is that our work may turn out too heavy and dark. To cure this, take a clean brush dipped in water *only* (without colour), and proceed to hatch the work generally, then, with an old, soft handkerchief, remove the loosened colour by rubbing gently.

Of course this latter portion will not very easily apply to a photographic base, but it can be made to do so if necessary. It must, however, be borne in mind that the *white spots* in question will seldom or never appear on a photographic base.

Having got this far, it will be time we thought about our backgrounds.

This is necessary because the depth and colour to be given to the face and hair is, to a very considerable extent, influenced, if not absolutely determined, by it. The effect of the white paper round the head is very misleading, and prevents us from forming a just and true estimate of the colours already laid on. For example, the white must necessarily make all the colours appear much darker than they really are, by contrast. This being so, let us work in a dark background; and what will be the result? why, these very flesh tints which before, by contrast with the white, appeared dark enough, if not too dark, will now seem pale in comparison with the background. As I intend taking the treatment of backgrounds a little later, I will not say much more about them now. I only wish it to be understood that now is the time to indicate our background, as we cannot really go on without doing so. I may, however, suggest that a very agreeable greenish background may be painted in by using either indigo and burnt sienna, indigo and sepia, or indigo and Vandyke brown. The best way to start a background is to apply the colour in washes indicating the various gradations of light and shade by a lighter or deeper shade of colour. It will be found advisable, as a rule, to keep the surface as flat as possible, and this effect is secured by a series of touches which are a kind of "cross" between hatching and washing. This portion of the work should be broad, generally becoming somewhat finer as it approaches the face. We may now, also, wash over the dress, and if there be any linen about the picture we should put in the shadows with a tint composed of cobalt and sepia.

We can now, with advantage, hatch in a light tint of blue over the lower and retiring portion of the cheek, indicate the bluish shadow below and at the corner of the lower lip, but do not fail to keep its form perfectly defined. We can proceed with this until we have gradually united it with the bluish shade of the jaw. Under the nose we must work a bluish tint, and also a little of our shadow colour on the wing of the nostril. Then soften as much as possible the edge of the chin, and make it round with the shadow colour.

There is generally a reflected light under the chin, which must be represented by a warm colour, such as a tint of Venetian red and Indian yellow would produce. Many look upon this as the flesh colour. A little of this colour should be worked into the dark shadows in the sockets of the eyes. The shadow side of the eye should be softened with shadow colour; then finish the lips by stippling them with pink madder and vermilion, observing that the brightest point should be that nearest to us. Indeed, the principal portion of the work at this stage of our painting may be said to consist of softening the tints by working upon their edges.

This may be said to represent the second painting, as far as the flesh is concerned. We can now proceed with the hair, strengthening the deepest shades with sepia. Painting hair is anything but easy. Its chief difficulty lies more in the *drawing* than in the *colouring*, for I do not think I am wrong in so designating the series of touches which represent the form and flow of the hair. To paint hair successfully will require much care and practice on the part of the art student.

To paint brown hair, use Vandyke brown and sepia for the local tint, and with a firm touch work in the deepest shadows. The really deepest shadows we have already marked in when securing the outline, but we must keep on repeating our touches with this tint until we have secured every gradation from high light to deepest shadow. Even the highest lights must be tinted with a series of light touches which will more or less truthfully represent hair, regardless for the present of the bluish tint always perceptible on or near the lights. Whatever high lights may be deemed necessary must be afterwards taken out. Should the local colour not be sufficiently warm, apply the flesh tint composed as before laid down.

Should we have to paint dark or black hair, the mode of working is the same, but the colour used is sepia by itself, and for the extreme shadows add a little warm black, such as would result from mixing sepia, lake, and indigo. Bear in mind that in black hair the lights are cold and bluish, and that there is a warm tint always between the extremes of light and shade.

For flaxen hair the treatment is the same, beginning as before with sepia, but of a proper degree of strength. The next darkest tints paint with Vandyke brown with or without sepia, then use the flesh colour. For the local colour use yellow ochre, or a tint formed of Indian yellow and Venetian red. The latter is naturally preferable, owing to its greater transparency, but the former has its *solidity* to recommend it. The high lights of flaxen hair are yellow, and between the lights and shadows there is a cool, grey tint. It is usual to take out the high lights of hair afterwards, the various tints being quite dry after being applied as described.

It is advisable to always introduce shadows or grey tints between the hair and the flesh, with the object of avoiding that hardness which would otherwise exist, also to soften the hair where it meets

the background, as, failing this, the head would look as though it were inland.

On the shaded side of the neck the colour to be used is a tint composed of Indian red and blue, on the light side blue alone will suffice. The greenish tint on the neck is obtained by hatching the flesh colour over the blue. In like manner treat the arms and hands, using, however, Indian red alone for the first tints, and applied in the same manner as we did to the forehead. We can then work over them with blue when necessary, but taking care not to miss the reflected lights, which are always of a warm tone.

To paint the divisions between the fingers use pink madder and brown madder. Observation will show that the tips of the fingers, the knuckles, and outside of the hands, are more rosy than other parts, and must be hatched with the carnation tint composed of madder and vermilion.

Now if we give a general wash over the *white linen*, if any, with a middle tint, regardless of any high lights, which we can take out afterwards, we will have completed our second painting. If we wash a local colour over the drapery, leaving the high lights for after treatment, we may consider our labours done, and look confidently to our third painting to complete our work of art.

If we thoroughly consider the foregoing we will find but little difficulty in applying all the directions for the production of a portrait in legitimate water colour to the treatment of a photograph. We have only to use our sense as we go along. The image on the photographic base, naturally, has a full and detailed outline, strongly marked in a more or less forcible tint; therefore, it would be foolish on our part to put in the shadows and other markings as we should upon a sketch. The reason for this is obvious; they are already provided by the photograph, and only require our help in imparting the local and natural colours. As a fact, almost all the directions are applicable, only in a modified form, and in a slightly altered rotation. Then we must be prepared to further modify our treatment according to the surface of the photographic base upon which we work. On albumenised and kindred papers all washes should come first, as it would be very risky, if really possible, to give a wash after having stippled or otherwise worked upon it. The probabilities are it would "lick up" and preclude any chance of producing a good picture. In working backgrounds we should not depend upon *picking out* or washing out the lights afterwards, but secure them at first and proceed to deepen our shadows. We may wash out a light, in cases, but, as I suggest, it will be advisable not to depend upon this mode of working, as its complete success is doubtful. I do not think there is anything else I can say regarding the second painting; and we may now look forward to our finishing or third painting, and one or two details, to complete our present undertaking.

REDMOND BARRETT.

REDEVELOPMENT: AN EXPERIENCE.

EVERY one is aware that the conversion of the metallic image that forms the negative deposit of a gelatine plate into silver oxalate or chloride is sometimes desirable, and that it is to be accomplished without much trouble, thereby some scope for influencing both the quantitative and qualitative character of the picture is revealed; as, for example, in the reduction of excessive density, and in the removal, or at least the partial abatement, of various kinds of fog—local, superficial, physical.

The application of a solution of ferric oxalate, or of a body having in its combination several equivalents of chlorine are two of the more widely known means for effecting the conversion, or, in the phrase commonly employed, the bleaching of the image. Precisely proportionate to the extent to which the reaction is allowed to proceed will be the dissolution of the silver salt by the hyposulphite. It is consequently to be perceived that by the play of a little caution and intelligence we hold the means of dispensing with whatever thickness of metallic layer—whether it take the form of general coloured fog, local fog splashes, or too great density of image—which it appears to us advisable to get rid of so that the negative shall have its maximum printing value, or be otherwise improved.

Within the field just indicated are gathered several other methods of reduction possessing features of general similarity. The main principle of nearly all the best known and effective of them does not depart from that already sketched. A particular exception, however, furnishes an opportunity for modifying that principle so as virtually to set up an alternative system of reduction. This consists of converting not merely the surface of the deposit, but, as far as is practicable, the whole of it into chloride or other soluble salt, and then carefully redeveloping up to the required degree of intensity.

While to some minds this last plan will have a resemblance to the Chinese formula for roasting pork, due reflection will, no doubt, suffice to bring home to the generality that where universal reduction of density is sought the operation has to be well watched, and that this *desideratum* is completely met by slow redevelopment.

It is not my present design further to dilate upon reducing formulae and their uses: the subject is one upon which a very great amount of valuable knowledge prevails, of which an increase is beyond my achievement. I propose briefly and tentatively to deal with the principles of redevelopment from a standpoint at the true antipodes of that from which they are usually regarded. It is, of course, almost unnecessary to remark that the photographic image, negative and positive, may be "converted" for a variety of ultimate purposes with which we are not on the present occasion concerned.

In the course of some recent endeavours to reduce by the method last detailed several negatives which erred not largely on the side of excessive density, a paradoxical phenomenon, or what was regarded as such, manifested itself. The "bleaching" solution used was cupric chloride. Upon the completion of redevelopment, the deposit, in contradistinction to what was expected, appeared to have made a sensible, but of course not great, gain upon its original opacity.

In attempting to trace this remarkable failure to its source, it occurred to me to try and ascertain if the seeming enhancement of opacity was or was not illusory, and, if not, whether the effect was obtainable deliberately. In pursuance of this determination the halves of a number of negatives were bleached and redeveloped. At first the results by no means appeared to confirm the "intensifying" property of redevelopment; but by repeated efforts, together with certain modifications in the developing solution, some show of success was at length had, and an apparent increase of density obtained, as was evidenced by a comparison of the redeveloped halves with the halves that had not been so treated. The developer successfully employed consisted of, in each ounce, hydroquinone, five grains; potassium meta-bisulphite, five grains; sodium carbonate, ten grains. My inference was that if to a bleached image there is applied a developer strong in reducing agent, poor in alkali, and relatively free of restraining substances, there is produced the equivalent of a serviceable increase of printing density.

It is reasonable that to an unqualified use of the word "density" in this regard, demur may be made without scruple, inasmuch as it would appear to imply that by redevelopment an additional layer of negative deposit is to be had. That, of course, could not be. If I were asked to suggest an explanation of the increased opacity, I should seek refuge in some such opinion as this: The physical consistence of the deposit undergoes alteration, inasmuch as the conversion into chloride being (presumably) not quite thorough, an exceedingly thin layer of unconverted metal remains beneath, upon which fresh metal is thrown in a state of coarse division caused by the vigorous action of the developing solution. Juxtaposition of the thin homogeneous layer with the rougher "top dressing" produces an apparent thickening and an appreciable diminution of translucency.

To suggest that if a thin image be converted to soluble silver chloride and treated with a developer an increase of printing density is to be secured at will involves a serious proposition, of which I am not yet eager to accept the responsibility. Moreover, at the first blush redevelopment in pursuit of opacity looks, I must own, uncommonly like the exercise known as progression in a circle—a perpetual return to the original starting-point, in fact. But if we agree that the action of the developing solution, in all its variations, upon (1) the invisible impression in gelatino-bromide, and (2) upon the "converted" negative, is of practical equality and similarity, a small counter argument is at once supplied to us. In case (1), with an exposure approximately correct, it is easy to construct an "image" of any density in the scale, varying from absolute opacity to almost perfect transparency, simply by the use, or misuse, of the developing agents; in the other (2) the image is rebuilt in absolute sympathy with the restrained constructive force contained in the developer. The parallel is obviously not complete at either end; and, although not indifferent to the mass of theory and practice opposed to it, in an attempt to bring the latter points opposite to each other I would choose to revert to a former speculation, and ascribe to the developing solution, when composed in the manner mentioned, or some such similar, the "roughening" action referred to, as the equivalent of the extremity of opacity produced in cases (1) and (2) alike.

But, to step on to more substantial ground than that of pure theory, I was unable always to get an increase of opacity, even with what I considered and found to be the best plan of redevelopment. The failures far outnumbered the successes; in fact, the latter were comparatively few, and were obtained under conditions that best favour intensification, namely, where, although the negative is ob-

viously lacking in printing density, there is yet a deposit sufficient to afford a "foothold" for the combining or displacing bodies. Radically thin negatives that would have been useless for intensification were no good for redevelopment purposes.

Could we establish the certainty that by any method of redevelopment a graduated scale of printing density was to be imparted to the negative at will, the far from satisfactory operation of intensification would stand a fair chance of being materially simplified.

I have sought in the preceding sentences to avoid the dogmatic manner, inasmuch as I should find it difficult to maintain the proposition that the "intensifying" property of redevelopment is anything but a curious and isolated phenomenon. Perhaps, however, others may be in a position to exhibit confidence in its constancy, and can refer it to definite and intelligible causes? THOMAS BEDDING.

MUYBRIDGE AT THE LONDON INSTITUTION.

On entering the hall, the first thing that attracted attention was the apparatus which was to illustrate the lecture. There was an ordinary biunial lantern, and a lantern of rather novel construction. The body was elevated on brass pillars about eight inches high, and a lens was supported about three inches from the front by a single pillar fixed in the top left-hand corner. A box sliding in runners containing gear wheels, and provided with a boss to which the various discs were to be fixed, was in front of the camera, and the top of the discs, when in position, were between the lens and condenser.

Professor Muybridge was punctual, and during a few preliminary remarks the lanterns were lit, one giving a little pop in the process, which disconcerted a few good people close by, who had been previously regarding the cylinders, the bright red one in particular, with a little uneasiness; but the pop not developing to anything greater, confidence was restored on the first picture being projected on to the screen. This was a sketch of reindeer, made by primitive man. Professor Muybridge explained that this was remarkable for its correctness in showing the walk of the deer, and he referred to it again later after he had shown a number of his own results.

Following on this, a description of the apparatus used in the investigations on animal motion was entered into. The battery of cameras consists of a long box divided into twelve or twenty-four parts, with a lens to each division. Plate holders are arranged at the back, and in front of the lenses in the exposing apparatus.

Each lens has its own shutter, an endless curtain on rollers. The shutters are liberated in turn by electricity. A commutator divided into twenty-four segments, with a brush bearing upon it, is used to send a current to the cameras in turn by wires connecting the different segments with the shutters. The brush is rotated by clockwork, regulated by a fan similar to that used in musical boxes. The rate at which the brush moves determines the interval between the exposures of the different cameras. The speed of the shutters is altered independently of this arrangement, electricity being used merely to release the shutters.

A track is specially arranged for the animals to traverse, and parallel to this a long battery of twenty-four cameras is arranged, so as to take the animal broadside on. Of these, twelve are found to be a sufficient number for most purposes. A second battery of twelve is placed at right angles to the first, to take a back view of the animal, and a third battery at 45° to the first takes the animal on the right shoulder. The shutters on these cameras work simultaneously, the corresponding camera, say No. 1 of each battery, is exposing at the same moment; it is found that the difference in working between the same cameras in the three batteries does not exceed $\frac{1}{17}$ part of a second. A chronograph is provided to register accurately the intervals of exposure, and the period of one phase in the animal's progression.

After describing the apparatus, Professor Muybridge showed a series of results obtained with it. The first slide showed twelve positions taken in each of the three batteries simultaneously, illustrating a horse walking; then followed a number of pictures of different animals walking—horses, a camel, mastiff, cat, lion, tiger, coon (which, by-the-by, was walking along a pole as a fly does on the ceiling), buffalo, cow, goat, hog, sloth, and, lastly, a child crawling. These all follow the same law, as does every other animal but the ape—according to Professor Muybridge's observations—in the placing of the feet in walking. The universal law is this: the laterals on one side will be close together, while the others are extended in front and behind. Now the ape, walking on all fours, has the *diagonals* together, and the other diagonals extended in front and behind.

Now, the explanation of this is fairly simple, and struck me as being possible at the time; but this morning I have been crawling round the room, and find that I am quite correct. The child was crawling on

hands and knees, and in thus crawling it follows the universal law; but the ape was walking on hands and feet. Now, if the child was to walk on hands and feet it will be found to progress as does the ape. The ape cannot, on account of its build, walk on hands and feet conveniently without transgressing the universal law, neither can the man for the same reason, namely, the arms being shorter than the legs; but if any one will take two short sticks in hand, so as to make the arms equal in length to the legs, he will at once, walking on all fours, follow the law as he did when shortening his legs to bring them to about the same length as his arms. I have no doubt but that the ape would walk in precisely the same manner under the same conditions. So the ape can hardly be said to be an exception to the law in walking, as under the same conditions—*i.e.*, with four legs of approximately the same length—he walks in the same manner.

After the explanation of this law the reindeer of primitive man again appeared, and be it said to the honour of our ancient forefathers that they were perfectly correct in representing a quadruped's walk, while many artists of the present day, who certainly should have had greater facilities of observation, have left works of art c' with glaring incorrectnesses.

There is one picture in the Louvre, a famous one, of a team of six oxen ploughing. In this picture six different ways of walking are portrayed, one of which, however, is correct.

Miss Thompson's picture, the *Roll-call*, shows a horse walking in the correct attitude. Miss Thompson was laughed at by both artists and critics alike, as also was Meissonnier for committing a similar crime.

Horses trotting have all the feet off the ground at one period; this Professor Muybridge has proved to the edification of certain great lights of the turf, who maintained that a trotting horse had always one foot on the ground.

The most absurd error that has been perpetrated in the history of art is the common representation of a horse galloping. The impression usually given by observing a horse galloping is that it has all its feet drawn up under the body, but in paintings it is almost always depicted as having all four legs fully extended in such a manner as to offer no support to the body, and to preclude any possibility of its drawing up its feet in time to prevent its crashing to the ground. One picture of the Derby, which is well known, shows ten horses all with legs fully, nay, more than fully, extended. This picture is, perhaps, the most supremely absurd effort of the imagination ever committed to canvas. Fancy the remarkable coincidence of ten horses racing together, and being at the same moment all in the same position, and that position an impossible one! At one period of the gallop the feet are all drawn together, so one wonders how the popular error has come about. When the back legs are flung out behind, the fore legs are close to, if not touching, the ground, and form, with the ground, an almost equilateral triangle. A sketch, most crude, by North American Indians, on horn, representing horses galloping, shows the legs correctly drawn together under the body.

A dog galloping exhibits the fully extended position imputed to the horse. Professor Muybridge thinks that all animals which can outstrip the horse for speed assume this position, but it is only possible with animals having great strength in the back.

A horse galloping—this is a curious fact—always has the nose vertically above the centre of the pastern joint of the foremost leg, and this is the case no matter what point of view the observer sees it from. Several famous paintings show how this point was unobserved by the artists.

With one picture on the screen, of a horse galloping, Professor Muybridge offered an apology for the indistinctness of a forefoot passing through the air; but in place of receiving his apology with grim silence, we greeted it with applause when he told us that the horse was travelling at the rate of one mile in one minute forty-two seconds, and that the forefoot must have been moving 150 feet per second; and calculating from the extent of the blur, the exposure given to the plate comes out at $\frac{1}{1000}$ second. The lenses used, it may be well to mention here, were specially made for these experiments, and have an aperture, if I remember right, of $f/2.5$.

Representations of a horse jumping are usually correct, as there is a hesitation or slackening of speed just as the jump is accomplished, thus rendering observation fairly easy; but in landing the horse always brings his forefeet to the ground first: this would seem only natural, but there have been various opinions even on this point. The pictures of the horse jumping shown on the screen were, I think, some of the clearest results from the rapidly exposed negatives. They were excellent.

Some of the most amusing pictures were of a mule. Professor Muybridge said that this mule was the best kicker he could get hold of, and called attention to the barometer which a mule always carries

with him, and which gives certain indications when calms might be expected and when squalls are imminent. This infallible barometer is the animal's caudal appendage, but, unlike our weather barometers, it rises when storms approach. It certainly was a very fine kicker, and might have left an impression of his hoofs on the face of the Russian giant, if that being had been in the vicinity.

There is one conventional method of representing birds flying which is adopted by most artists, viz., with the wings extended upwards. Why this should be is strange; of course, it is the most artistic way to us now that we are accustomed to it, and any other position would look strange and unreal, but I, for one, greatly admire the variety and artistic taste of the Japanese, whose efforts in the representation of birds flying are now proved to be almost entirely correct. In this point, as well as in others, we are decidedly behind the Japanese in art. The pictures of a white cockatoo shown by Professor Muybridge were most remarkable; the most striking position of the wings is when they are just finishing the downward stroke, a position the Japanese are very fond of, and in which the Egyptians always represented the sacred hawk. Just as the downward stroke is finished, it is an interesting fact that the feathers rotate simultaneously, and present only the edge to the resisting air until the upward stroke is finished, when they overlap again to give the fullest effect to the downward stroke.

A number of pictures of *humans* were shown performing all kinds of actions. A woman emptying a pail of water was splendid, the water being clear and distinct in its different positions on its way from the pail to the ground.

A girl walking down steps carrying a breakfast cup and saucer was very good, and if it had been the work of an artist would have called forth loud praises from critics. But the prettiest of all was a series of pictures of a little girl picking up a doll which she had been told she might keep if she fetched it from the track, and carrying it off in triumph. The expressions of the face were splendid: the uncertainty of the youngster as she approached the doll, the pleasure with which she picked it up, the glance round to see if all was right, and the happiest smile as she prepared to run back to her mother.

I have not said much at present about the "zoopraxiscope," as a connected description is better than a remark here and there. I have described the lantern and the general arrangements.

A glass disc, about fifteen inches in diameter, fixed to the boss, has the pictures arranged in order near the edge. These are reduced from the negatives, and in most cases painted black, so as to give simple silhouettes. By this means the effect of the change of position in each picture is more marked. In front of this is placed a zinc disc with radial slots—one slot in excess of the number of pictures on the glass disc. The extra slot gives a forward motion to the animals across the screen. The discs are rotated at the same speed in opposite directions, and the figures rapidly following each other appear on the screen as a continued movement of the animal. It is not merely a picture of one animal that careers across the screen, but a number following close behind one another, and all performing the same action. So, to get the full effect of the different phases of the motion, it is necessary to "fix" one as it comes on the screen and follow it across; the effect is very fine and of course perfectly natural. We had horses walking, trotting, cantering, galloping, and jumping, with long flowing tails waving behind in the most lively manner, while the rider of the galloping horse flourished his whip with every sign of urging the animal to its utmost. A dog tore across the screen at full speed, and we could see how much the back helped in the work. Then an acrobat turned summersaults on the back of a galloping horse, his arms swinging backwards and forwards as he got up steam just before his leap. And finally a hawk flew over the screen, showing the whole of the most interesting motion of flight, even to the turning of the feathers when the discs moved slowly.

W. P. ADAMS.

CONCURRENT DEVELOPMENT AND FIXATION.

[A Communication to the Photographic Club.]

You will remember that at our last meeting Mr. Davis stated that a friend of his had witnessed the development and fixation of a bromide of silver gelatine plate in one single solution. There seemed to be no one present who had any knowledge of this matter, and to be left as a question needing investigation.

I have no doubt that most of us then present were of the opinion that if such concurrent development and fixation were possible, that it would possess very little practical value, and to that opinion I still hold, though I have subsequently proved that it may easily be done.

Last Friday evening I was thinking over the problem, and it

occurred to me that I had the means at hand by which it could be accomplished. It was our friend Mr. Wellington's redeveloper that seemed to promise to be the very solution to answer the purpose, for it contains *two* fixing agents and a pyro developer.

I have already spoken here of a slight modification of mine of this method of intensification, which somewhat simplifies the operation. I take first a solution of nitrate of silver, 100 grains to five ounces of water; second, 240 grains of ammonium sulphocyanide to five ounces of water; and, third, 240 grains of hyposulphite of soda to five ounces of water. These can be kept separately any length of time, so far as my experience during the present year allows me to judge. To re-develop an already developed and fixed plate, either gelatine or collodion, take a drachm of each solution and place into one measure in the above order, and add thereto twenty minims of a ten per cent. solution of pyro (say sulpho-pyrogallol), and twenty minims of a twenty per cent. solution of ammonia. This may be poured on and off the plate as in the old days, a little glycerine making the adhesion to the plate more complete.

Now, in regard to the concurrent developing and fixing, I thought I should attain the object more certainly if I added a larger proportion of ammonia pyro in the first instance, so as to start the development before the fixing agents could have time to act, so as to reduce the part which had received the image. I therefore took a drachm of each of the five solutions, and added enough water to make it cover a quarter-plate. Taking the first negative which came to hand, a weak one as you may judge by the positive, I exposed it thirty seconds and put it into the solution. It did not develop as rapidly as usual, and the fixation was somewhat prolonged on account of the weakness of the fixing portion of the solution. There was an appearance of fog, which was due in some measure to the thinness of the negative, and a considerable amount of non-adherent silver was thrown down on the plate and the dish, which I sponged away. To test if the image was really fixed, the plate was partially immersed for some time in hypo, which had no further effect. This plate is marked No. 1.

The next experiment was to see if the development would take place when the pyro ammonia was added to the fixing agents without the presence of the silver nitrate. The silver was omitted, and the plate soon became quite clear glass without the trace of an image. It thus seems that this method of development demands silver in the developer, in a manner analogous to that known to all collodion workers in all processes where the alkaline system was not used. It will be seen also that by the dissolution of the bromide of silver by the fixing agents, the solution becomes somewhat like Mr. Howard Farmer's intensifier, and development goes on after the fixation has been effected, as, indeed, might have been anticipated from the known use of the solution as a redeveloper.

The second example was treated in the same manner as the first, except that it was exposed half the time, and was not developed so long, and is therefore thinner, though it is probable that a longer immersion would have given greater density.

I regard this as simply a photographic curiosity, for I cannot detect anything in the process that promises improvement upon previous methods; indeed, it seems to point the other way, for the time of developing is considerably increased, and I should say that the separate solutions would do the work in a shorter time. Those who have time and taste for experimenting will doubtless find the matter interesting, and we may yet hear more of it. W. D. RICHMOND.

CAMERA CLUB.—REJLANDER'S PICTURES.

On Monday last, December 16, the Camera Club opened the fifth of its series of "One Man" Exhibitions, the pictures shown being a collection of the work of the late Mr. O. G. Rejlander.

Mr. Francis Cobb opened the Exhibition, drawing attention to the distinctive feature of Rejlander's career, that he was the first in photography to see and prove some of the higher possibilities of the camera as applied with an artistic aim to portraiture and figure subjects. He also alluded to the amiable personal character of the artist, his training as a painter, his devotion to, and faith in, photography, and at the same time his readiness to admit its limitations. In referring to the pictures in the room, Mr. Cobb mentioned specially *The Two Ways of Life*, an elaborate attempt to illustrate pictorially the opposite courses of virtue and vice. In this photograph, he stated, over fifty negatives were said to be combined.

Of the other work, perhaps the most notable are the clever humorous subjects which are well known to photographers and the public. *Gin's Baby*; *She is looking at me, the dear Creature! Catching—Caught! Cats caught by Rejlander*; *Did She? I don't know*; and others. Amongst other

interesting photographs are *Dr Brown and his Dog* (Rab and his friends), and portraits of Tennyson and Doré.

Also the strange attempt to depict by photography such subjects as *John the Baptist's Head in a Charger*, and *A Vision from Aspromonte*. (Rejlander posed himself as Garibaldi in several photographs.) Perhaps the most completely satisfactory of the pictures are those in which Rejlander devoted himself to representing incidents of street-arab life. In these bits of humorous characterisation, he showed himself a master as regards infusing his idea into his models and securing natural and spirited expression of the subject. *Adding Insult to Injury*; *Is it a good 'un, Jem?* and the pathetic figure of the little waif huddled up on the steps, are especially effective.

After the opening of the Exhibition (which will continue for about six weeks, and is open to visitors on presentation of card), an exhibition of very fine lantern slides was given upon the Club screen.

NOTES FROM NEWCASTLE.

The Cycling Club in connexion with Messrs. Armstrong, Mitchell, & Co.'s works at Elswick, purpose, I hear, going in heavily for photography next season. The majority will be provided with small, specially made cameras, and runs are to be organized for the purpose of photographing bits here and there. As the Club numbers some 350 members, this should mean a considerable influx of amateurs to the present well-filled ranks.

I strolled through our well-known Dene at Jesmond the other day; the sun was shining, and the trees, though destitute of leaf, looked very charming. I passed altogether six cameramen, which proves that our enthusiasm does not cool with the time of year.

I don't hear much of the doings of the Y.M.C.A. Photographic Club, but I hope they are pegging away. The removal of Mr. Weeks, the late Secretary, was a less no doubt, but should not be quite irreparable.

The premier local Society held their usual monthly meeting on Tuesday, the 10th instant. I hear that the President, Vice-Presidents, Hon. Secretary and Treasurer, and most of the members of Committee were re-elected, or rather, to be more exact, no new blood was nominated. A change of Executive is not necessary nor desirable, but I must confess I would like to see some more ambitious members put on the Council. A very large collection of "snap-shot" pictures were distributed over the tables, the results of various competitions get up by one or other of the newer photographic journals; and, generally speaking, the pictures were very good. An assortment of lantern slides was then shown on the screen, to the satisfaction and enjoyment of all present. Mr. Hedley Robinson, a past master in these matters, manipulated the lantern with his usual success. Mr. Robinson is also an expert slide maker by the collodion method—he succeeds in getting admirable density and colour.

The Society has at last screwed up its courage to the necessary pitch, and it is decided to hold an exhibition of photographs in April of 1890. A good working Committee has been appointed to carry out the arrangements. I hope to have further details shortly, but it is, I am assured, definitely settled that the exhibition will be opened on April 18 with a *conversazione*. This date will allow ample time for the removal of frames from the Crystal Palace Exhibition, from which it is hoped the Newcastle show will be largely supplied. The *locale* of the exhibition will be the Central Exchange Art Gallery, which is a handsome structure (to quote Tomlinson) at the upper part of Grainger and Grey Street, "built after a model of the Corinthian Temple of Vesta, at Tivoli; the interior is a noble semi-circular area of 11,000 feet, and is used as an art gallery and reading room." This is one of the most central and popular resorts in Newcastle, the entertainments being of a high-class character. The Committee are fortunate in coming so soon to terms with the lessees, Messrs. Barkas & Son. There will be ample space here, and I hear that arrangements will be made so that an exhibitor may, if he chooses, have a screen to himself; this will, in a great measure, prevent the "scattering" so annoying at most exhibitions. D. D.

NOTES UPON A PROPOSED PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.

[A Communication to the Birmingham Photographic Society.]

My subject may be considered as an extension of a paper which I read before the Birmingham Photographic Society in June, 1885, on *The Work of a Local Photographic Society*. Permit me to quote two paragraphs from that paper:—

"Within the last few years photography has made a new departure. The introduction of gelatine dry plates and films has made the process so clear, and—by comparison—so easy, that photographers have multiplied a hundredfold. Oh! that we could bring back Daguerre with his costly silver plates which required such tremendous polishing, Fox Talbot with his calotypes, and Scott Archer with his wet collodion plates, silver bath, and travelling tent, which made the landscape photographer's life a burden to him, and show them our light and complete equipment, with which a man may travel round the world and leave if he pleases, his pictures to be developed by his grandchildren, with

be derived from the Celtic *Gaur*, a fortified place, and *Wicci*, the tribe by which that high mound, which at Warwick overlooks the Avon, was raised and defended.

W. JEROME HARRISON.

(To be continued.)

PHOTOGRAPHIC FANCIES IN NEW YORK.

A NEW YORK correspondent of the *Boston Sunday Herald* writes:—It shall no longer be said that woman's brain is not inventive. I hereby provide the disproof, and my original devices are in the line of amateur photography. There is hardly a fashionable house in New York where we fail to meet the young man who, without a word of warning, helps himself to an instantaneous portrait of us; and we cannot spend an evening with a friend but that the mistress announces to us, in the tone of a Lucretia Borgia, "Ladies and gentlemen, you have all been photographed." Resistance would be useless, and whatever may be our disinclination to see ourselves reproduced with a sincerity too often unflattering, the best thing to be done is to let it pass with a smile, for a grimace might only aggravate the condition of the victims. The progress of amateur photography has been rapid, and my inventions seek to utilise it. I have planned a photographic revolver—an instantaneous apparatus whose name indicates its form. It suffices to press the trigger on sighting a person in order to obtain an instantaneous portrait. I consider it useless to enumerate the advantages which this weapon has for a revival of duelling. Very soon we may read such items as this: "In consequence of a difference of opinion between Mr. X. and Mr. Z., a meeting was agreed upon. The weapon chosen was the photographic revolver. Two portraits were exchanged without fatal results." I also propose a photographic shot-gun, which will bring the sport of hunting within reach of the members of the Society for the Prevention of Cruelty to Animals. Naturally, the mere existence of the beast's portrait on the plate will show that the shot has reached the mark, and the sportsman's vanity—which is the real source of the love of hunting—will be satisfied without the shedding of blood. In case of the fish-line, one can simply replace the flies or angle-worms by a tiny camera, which the jerking of the fish will bring into action. The portraits thus obtained will have the advantage of preserving their freshness much longer than the original, even in the hottest weather.

Undoubtedly the instantaneous camera will show equally important adaptations to the needs of city life. The photographic piano, which takes a picture every five minutes of the guests surrounding it, will cause a *furor* in society this winter. In the supper room a photographic register, usually concealed at the base of an *epergne*, will permit the host to see if thirsty guests abuse their privileges. It is always a good idea for the mistress of the house to have some information on this subject. People of celebrity are always a prey to the amateur photographer, and in the hope of abridging their sufferings I project an ingenious apparatus which, while photographing the subject, writes at the foot of the card a flattering inscription. I should also mention the millinery camera, which takes the picture of every person to whom the wearer of a hat or bonnet bows. On going home it is sufficient to compare with one's album the proofs there obtained in order to recall the people whom one has met. This is very valuable to those who have many acquaintances and a short memory.

MISS LOOKABOUT.

Foreign Notes and News.

THE American laes, "zapon" and "brassoline," have been recently subjected to a good deal of experiment by Max Jaffé (*Photographische Correspondenz*). In order to test the capacity of resistance to the action of water, he coated a collodion and a gelatine negative with ordinary negative varnish (shellac and alcohol), and two of each sort with "zapon" and "brassoline." After drying each negative it was placed under several layers of damp blotting paper and weighted. After twenty-four hours the water had penetrated everywhere through the coating of the gelatine negatives, and softened the gelatine in the case of the "zapon" to such an extent that the film could be easily removed from the glass. In the case of the collodion negatives coated with shellac and "zapon," the films become moistened through to the glass after a few days; with "brassoline F.F.," a few cloudy spots showed themselves after fourteen days; with "brassoline H.H.," no alteration was observable even after forty-five days, from which it appears that this material is very superior to shellac. M. Jaffé is now proceeding to test these varnishes in regard to their tendency to crack, and will, doubtless, soon publish his results.

ALEXANDER LAINER, in the *Photographische Correspondenz*, gives his experience of the compound alum fixing bath. "The great advantage of the mixed alum bath," he says, "is that it causes immediate induration of the gelatine, and that the film is hardened at the same time as the fixing is accomplished, and counterbalanced by the constantly recurring clouding which the alum bath occasions. This is not prevented by neutralising the alum. Sodium sulphite, however, produces a different effect. On adding a saturated solution of sodium sulphite to a saturated alum solution a precipitate is formed, which on shaking disappears, accom-

panied by the evolution of sulphurous acid. On mixing the solution with an equal volume of the fixing bath it remains clear. The following receipt acts well:—

Saturated solution of alum	1000 parts.
Saturated sodium sulphite solution	200-300 "
Fixing bath	1000 "

This bath remains clear for fourteen days even in open vessels. If one takes only 100 parts of sodium sulphite solution the bath will keep longer. With different kinds of alum, different amounts of sodium sulphite will be found sufficient; sometimes only forty parts of this latter solution will suffice to make the bath keep for eight days."

THE following bath, says Liesegang's *Archiv*, originally recommended for plates developed with eikonogen, is very well adapted for gelatine plates and bromide of silver paper, however they may be developed, one of its advantages being that it always keeps clear and prevents yellow colouring of the negatives from taking place when alkaline pyro is employed. This is the receipt:—

Fixing soda	200 grammes.
Double sulphite of soda (otherwise known as acid sulphite).....	50 "
Water	1000 "

This fixing bath has the following advantages: 1. It gives the negatives an excellent tone which permits of very rapid printing. 2. The bath remains clear even after frequent use. 3. The alum bath previous to the fixing is dispensed with, and consequently the possibility of a precipitate of alumina forming in the films through insufficient washing is removed. If the nature of the plates used render the hardening of the film a necessity, an alum bath may be employed; but the alum solution must not be stronger than fifty grammes to the litre, as otherwise it easily produces bubbles in the gelatine.

A RECENT number of the *Photographische Rundschau* contains an article by Alfred Stieglitz on the *Influence of Temperature in Development*—a subject generally rather neglected, both by professionals and amateurs. At a temperature of thirteen degrees, he points out, development requires five times the time necessary at a temperature of fifteen degrees, and negatives that develop harmoniously at the latter temperature become at the former extremely hard. At seventeen degrees the same developer is nearly sure to overdo the negative. It follows that the temperature of the developer is therefore of quite as much importance as length of exposure and concentration of solution. In order to develop with regularity, one ought to warm the developer in winter, and in summer cool it. Over-exposed plates ought to be treated with coldness, and instantaneous views with warmth. We should say that the exasperated amateur is under the circumstances likely to treat them both with warmth, especially if the too long exposure in the former case has robbed him of a fine landscape. This, however, is probably not the kind of warmth intended, as it leads more frequently to fracture of the unsatisfactory plate rather than the clouding the learned but phlegmatic German appears alone to dread. The whole series of observations seems rather to savour of hair-splitting—as if there were no such element in controlling development as time!

DR. STOLZE seems to take the same view of the matter, as he devotes a good deal of criticism to the article. "How are you going to cool the developing bath," he asks, "in summer, with the thermometer at 25° C. or 30° C. in the shade?" It is all very well to try and cool it with ice, but if you take it out of the ice the temperature at once begins to rise, and if you keep it in it gets too cold. Even in a regular studio you cannot get a temperature of 15° with regularity. And what is the unfortunate photographer to do when on the jog? He cannot find ice in any pond in summer, and if he is going to carry nitrate of ammonium with him for every operation, his burden will be as big as that of Christian in the *Pilgrim's Progress*, and his own progress probably not much faster. Dr. Stolze very sensibly continues that the best thing to do in summer—in winter one can warm up easily—is to alter the composition of the developer in accordance with the general temperature, so that it may not act too quickly. This may, of course, be done by the use of restrainers. Where, for instance, in winter one works without bromide of potassium, one may employ it in larger or smaller quantities, according to the prevailing temperature.

Our Editorial Table.

PHOTOGRAPHS OF SOUTHERN LIFE AND SCENERY.

By O. PIERRE HAVENS, of Jacksonville, Florida, U.S.A.

A CLEVER Northern artist who has settled in the commercial capital of the Flowery State, Mr. Havens has not been slow to perceive that in its varied scenery, and especially in its coloured population, lay much that might be made conducive to artistic subjects for his camera. Nor, to judge from a parcel of pictures received from him,

has he been slow to avail himself of such subjects. Some of these are exceedingly mirth-provoking, such as—"I 'specs I've born tired," representing a coloured boy leaning against the trunk of a tree in a pine forest, and enacting the sentiment expressed in the title; *Cherubs*, in which a couple of nude young "niggers" are seen leaning over a rocky wall, with the well-known palmetto fans so arranged behind them as to convey the idea of circular wings sprouting from their shoulders: a pose which may shock some of the naturalistic school who profess to admire the pictures of Mrs. Julia Cameron, but who forget, or may not be aware, that this lady when photographing a cherub attached a pair of the wings of a goose to the shoulders of the innocent model. Not having ourselves been privileged to behold a real live winged cherub we are unable to say which of the two, Mrs. Cameron or Mr. Havens, is nearest to the mark in this matter of wings. Perhaps both may be right, and it may be, after all, a difference depending upon degrees of latitude. A characteristic picture is the group of ten of a family all engaged in that occupation of all others the most congenial to the southern negro, *viz.*, eating water melons, or "milions" as the fruit is designated by them. Others of the series are—"I've a Dude;" *Ancient Seal* (a "darkie" fishing in a stream overshadowed by the Spanish moss depending from the branches of the live oak); "*All Mine*" (the sable father of a numerous progeny arranged under the shelter of a log cabin, and indicating his proprietary interest in them), with other subjects of like nature. The size of the pictures is 8x5, and as photographs they are unexceptionable.

VIEWS IN NORTH WALES.

By EIST ACRES.

THESE views are all in duplicate, one of each being taken on an ordinary plate and an isochromatic plate, both exposures in each case being made one immediately after the other, so as to ensure identity of lighting. The subjects are for the most part rivers or mountain torrents with steep tree-clad banks, *e.g.*, *The Fairy Glen*, *Below Swallow Falls on the Llugwy*, *The Lleder Valley*, *Beltwa-y-Cord*, and such-like. Those on the ordinary plates are very good indeed when we consider that they were taken on a dull afternoon in the end of October, and the detail in the foliage is well defined, although there is a monotonous sameness in it. On turning to the corresponding picture in the isochromatic series the difference is at once perceptible; the sombre uniformity which pervaded the wooded *entourage* gives way to a series of trees, some of which have colour values evidently widely apart from those of their fellows, and thus imparting an individuality to each tree quite absent in those on the ordinary plates. For testing the real advantages of colour-sensitive plates no subjects could possibly have been better selected than those in the prints before us, showing as they do nature with foliage which has put on its rich and varied autumnal tints. The negatives from which all the above prints were produced have also been sent for inspection. They bear evidence of careful, honest manipulation, and are untouched.

OUR HOME IN AVEYRON.

By G. CHRISTOPHER DAVIES and MRS. BROOKHALL. (Edinburgh and London: W. Blackwood & Sons.)

WE have often recommended, and it was safe enough to prophesy, that tourists and travellers would make the camera an adjunct to the pen when making notes for publication. *Our Home in Aveyron* shows in what an effective manner the two may be conjoined. Mr. G. C. Davies, when on a visit to his brother and sister in the South of France, had taken with him his camera, and we have as a result a most interesting volume, charmingly illustrated. But at this stage we allow the writer to speak for himself. We must previously, however, allude to a conversation with his sister (a resident in France), in the course of which she says that photographic apparatus is as well understood by the French Customs officers as in England, and more respected by the officials, and that curiously enough almost every Englishman who visits that part of the country on mining business is a photographer, the natives looking upon a camera as a necessary and usual appurtenance to an Englishman. Mr. Davies says: "Before proceeding further I pause to explain the *raison d'être* of this book. I took a great many photographs, of which I afterwards made lantern slides, and with the aid of my sister's notes and my own observations I retailed the information in the shape of lectures to rural audiences, with the view of aiding my clerical friends in their parish work and of benefiting institutions in which I took an interest, as every man should do who has the chance at little trouble and little expense to himself, and according to a laudable custom which is fast gaining ground among the army of amateur photographers—an army which sends skirmishers all over the world. I have, in doing this, found that much more interest was exhibited in the simple details of home

life, which might easily be compared with one's own modest experiences, than in more ambitious tales of travel, adventure, and discovery."

This amalgamating of description and illustration imparts a great charm to the book, for while as regards the former it is well written, the word-painting being all one could desire, the photographs are skilfully taken with respect to artistic selection of point of view and light and shade, while technically they are full of detail and plucky without. The subjects, too, are interesting. In a village scene, *Wine-shop and Auberge, Bouillac*, we see about a dozen pigskins full of the wine of the country suspended on the wall of a building; in the *Château Salgriac*, we have a near view of what was doubtless a strongly fortified place in the pre-Armstrong gun period: a *Religious Procession* at the fork of a country road—an instantaneous view and probably one of the finest in the book; *A Peasant's Cottage, Blanchissens, La Roque Torrac*, showing four merry washerwomen busily at work; with many others illustrative of life and character in an imperfectly known French country. The illustrations are printed on thick fine paper by one of the now numerous phototypic processes, and the book is got up in such a style as to reflect the highest credit on all concerned in its production, and to serve as a model for others of like nature.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
December 21	North Middlesex Club	Jubilee Hall, Hornsey-road.
" 21	Bottom Club	The Studio, Chancery-lane, Bolton
" 26	Burton-on-Trent	The Institute, Union-street.
" 26	Halifax Photographic Club	Mechanics' Hall.
" 26	Liverpool Amateur	St. George's-squares North.
" 26	Oldham	The Lyceum, Union-st., Oldham.
" 26	London and Provincial	Masons Hall Tavern, Basinghall-st.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 12.—Mr. J. J. Moran in the chair.

Mr. P. Everett showed the two halves of a divided negative, one half of which had been treated with ferrieyanide of potassium and bromide, and afterwards redeveloped, as shown at a previous meeting. Prints from the two halves were also shown; the difference was very slight.

This being a lantern night, slides were exhibited—the work of Messrs. Atkin Kerr, J. H. Smith, Teape, Wellington, and Hastings. The exhibits of Mr. Atkins were considered to be remarkably good in gradation, and inquiries elicited that they had been produced upon commercial plates as used for negatives developed with eikonogen.

Mr. R. P. Drage was elected a member.

CAMERA CLUB.

DECEMBER 12.—Mr. A. Pringle in the chair.

Mr. E. FERRERO explained a focimeter he had made for enlarging purposes in which the actual distance of object and image from lens was given on the scale of the instrument.

Mr. SHURTON exhibited a collapsing American clothes drier which he had found eminently suited for drying prints or films upon. He also showed fish glue strips for binding lantern slides. These strips were made from gum sheets produced by Messrs. Dennison.

Mr. CHARLTON WOLLASTON then read a paper on *Timing Shutters*, in which he criticised the several well-known methods of timing shutters; and, after describing the process he wished to put forward, he produced the apparatus and gave a demonstration of its action. The instrument was devised to give

record of the exposure given by the different portions of the lens from centre to margin during the opening and shutting.

In the discussion the Rev. A. B. COTTON exhibited and explained a small camera he had made for the purpose of timing shutters.

Mr. H. STURMEY described Wilson's shutter chronograph, and exhibited plates showing tests made with a great variety of instruments.

Several shutters brought by Mr. Wollaston, and some lent by Messrs. Hulton & Co., were on view to illustrate the subject under discussion.

On Thursday, January 2, lantern slides will be shown on the screen.

WEST LONDON PHOTOGRAPHIC SOCIETY.

DECEMBER 13.—Mr. Bilton (President) in the chair.

The following question from the question box was read:—"What is the best means of blacking diaphragms when worn bright?"

Mr. E. W. FOXLEE said if clean brass was immersed in a weak solution of bichloride of platinum the metal would be darkened, but the colour was not very good.

Mr. BLACKMORE had used for other work, though not for diaphragms, a solution of eight parts hydrochloric acid and one part of white arsenic. After prolonged digestion the metal was immersed in the solution and then gently dried before a fire.

Mr. J. A. HODGES wished to know whether the colour so obtained was of a permanent nature, or merely superficial and liable to be easily rubbed off.

Mr. BLACKMORE said the solution seemed to affect the surface particles of the brass itself.

The PRESIDENT had tried the effect of a solution of forty grains of silver nitrate in one hundred minims of water added to another solution of forty grains of copper in one hundred minims of water. The stops were dipped in the solution and then subjected to heat; the result was disappointing, the colour produced being greyish-black, and producing strong deposit on the brass itself, which upon analysis proved to be nitrate of silver.

Mr. STEIN then read a paper on *Defective and Hand Cameras*, after which representatives from the firms of the Eastman Co., Rouch & Co., Mawson & Swan (Mr. Winter), Fry & Co., Abrahams, Shew, and Marion & Co., explained the working of the cameras made by their respective firms.

The PRESIDENT, in thanking Mr. Stein for his paper, and the gentlemen who had attended with cameras, said that the subject was of such importance that it could not be properly dealt with in the short time remaining at their disposal. He therefore suggested that the discussion should be adjourned to the next meeting, which would take place on Friday, the 27th instant. As the meeting was also a technical one, he requested members to bring with them any matter which might be of general interest.

WEST KENT AMATEUR PHOTOGRAPHIC SOCIETY.

DECEMBER 11.—Mr. Dresser in the chair.

Two new members were elected.

Mr. Donkin showed a number of platinum prints on linen, and then read a paper entitled *The Motive Power of Photography*. After briefly sketching the progress of the art for the last fifty years, he proceeded to compare the standards of artists and photographers, and submitted that although photography was so young it had already taught several valuable lessons to artists. The motive power was "truth," and he held this was one of the great advantages of photography. In connexion with this he gave the following example:—Several artists and one photographer were appointed to represent a certain scene of nature; when results came to be compared, the verdict must be that the photographer's result was the most truthful. His perspective and the correctness of his drawing were indisputable, while the relation of the various lanes was nearly, if not quite, correct. The results shown by the artists differed in each case, and although each was a representation of the same scene, it must be admitted that the photograph was the true representation.

Next meeting, Wednesday, January 8.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

SPECIAL general meeting was held at the Society's Room, Grand Hotel, Moore Row, on December 11, to "consider the feasibility of making a photographic survey of Warwickshire, the object being to secure an accurate and unbiased record of the scenery, monuments, life, natural history facts, &c., of the county as they now exist." Mr. J. B. Stone, J.P., F.R.S., F.G.S., presided, and there was a good attendance, including representatives from most of the scientific, literary, and artistic societies in the county.

The circular convening the meeting having been read by one of the Hon. Secretaries (Mr. J. H. Pickard), Mr. STONE said that he took this opportunity of returning them thanks for the honour they had done him in electing him as their President in succession to a man so distinguished in science as Dr. Hillar. He called attention to the splendid work done photographically in connexion with the geological survey of the United States, and expressed the opinion that there was no branch of science in which it could not render most useful aid.

Mr. W. JEROME HARRISON, F.G.S., then read his paper, entitled *Some Notes on a Proposed Photographic Survey of Warwickshire* [see page 828].

The PRESIDENT proposed the following resolution from the chair:—"That a committee be appointed, consisting of the Council of the Birmingham Photographic Society, together with representatives from each local society (scientific, literary, or artistic) which is willing to co-operate, to consider the best means of making a photographic survey of Warwickshire, and to report to a future meeting." He urged the necessity for carrying out the scheme, describing the manner in which objects of the greatest interest were continually disappearing, on decay, accident, &c.; and giving as illustrations the "ducking stool" in the crypt of St. Mary's Church at Warwick; the old chair at Astley Castle used by the Duke of Suffolk when he hid in a tree to escape capture; and the traits of the conspirators in the Gunpowder Plot which are in Combe Hey.

Professor HILLHOUSE (Mason College) seconded the resolution, saying that he thoroughly believed in photographic surveys. At the Mason College the plan which he had urged, of each professor being photographed on joining the staff, had already given interesting results. Speaking as a botanist, he said that a photograph of *Osmunda regalis*, growing in boggy ground at Moseley, near Birmingham, would furnish a proof that could not be gainsaid that the plant really did once grow there, a fact which was now disputed. In attempts to acclimatise plants, photographs taken at frequent intervals would be of great service. He strongly emphasised the statement which had been made by the President, that there must be no "doctoring" or "retouching" of any of the work done in connexion with the survey.

Mr. JETHRO COSSINS (Archaeological Section of the Midland Institute) said that the charming village scenery of Warwickshire was changing with a rapidity which few imagined. Again, he quite lately found a farmer near Oldbury pulling down a small Norman chapel which formed part of an ancient castle. The churches of Warwickshire have already, for the most part, been "restored," so that such a scheme as this photographic survey was wanted long ago.

Councillor ANDREWS (President of the Coventry Photographic Society) sympathised with the scheme, but thought it was rather an enormous one. Of one ancient church in Coventry alone he had secured one hundred and twenty negatives before its restoration. He hoped, however, that the movement might be carried to a successful issue.

MESSRS. H. STURMEY and F. W. DEW (Coventry) agreed with Mr. Andrews; and Mr. SturmeY proposed that the Committee to be appointed should report to another meeting, to be held at an early date, as to the exact manner in which the survey should be carried out. This was agreed to, and words to that effect were incorporated in the resolution.

Mr. E. C. MIDDLETON said that the scheme had his entire sympathy and support. The pictures must be printed by a permanent process, and the use of wide-angle lenses must be avoided as much as possible.

The resolution was carried unanimously.

The PRESIDENT then proposed, "That the best thanks of this meeting be given to Mr. Jerome Harrison for his admirable paper, and that it be printed and distributed to the members of this Society, to the other photographic societies, and to the press."

This was seconded by Mr. W. B. GROVE, M.A. (late President of the Birmingham Natural History Society). He urged the importance of photo-micrography, especially of a tribe of plants in which he was much interested—the fungi.

The motion was carried and suitably acknowledged by Mr. Harrison.

The meeting concluded with a vote of thanks to the President, proposed by Mr. B. KARLESK and seconded by Councillor ANDREWS.

In addition to the names given, we noticed among those present Messrs. Jonathan Pratt (Royal Society of Artists), Councillor Wallis, Drs. Nicol and Donovan, Messrs. J. H. Stote, H. J. Whitlock, S. E. Baker, J. E. Bagnall (Microscopical Society), J. Landon, F.G.S., J. Udall, F.G.S., E. W. Badger, W. H. Vernon (Midland Arts Club), in addition to Messrs. E. H. Jacques (Vice-President), A. J. Leeson (Hon. Secretary), and many members of the Birmingham Photographic Society.

DERBY PHOTOGRAPHIC SOCIETY.

DECEMBER 9.—Mr. Richard Keene presided.

Mr. E. J. LOVEJOY, the retiring Hon. Secretary, presented the Committee's annual report and balance sheet, which were adopted.

It was decided to hold a *conversazione* in January, for which an attractive programme is in preparation.

This Society is now in a flourishing condition, having acquired a large lecture room, with a dark room attached, for the use of its members.

IPSWICH PHOTOGRAPHIC SOCIETY.

DECEMBER 10.—Mr. J. Dixon Piper (President) in the chair.

The subject of the evening was *Platinotype Printing and Development*, and Mr. W. VICK demonstrated the hot bath process, developing several prints from negatives made by him of the Society's excursion to Playford and Bealings.

The Platinotype Company lent several fine prints for the evening, and Mr. V. Blanchard sent several specimens of his new toning process, and the Hon. Secretary exhibited others toned by him by Mr. L. Clark's process.

The date of meeting was unanimously altered from the second Tuesday to the second Wednesday in the month.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

DECEMBER 10.—Mr. James Brown in the chair.

A series of over one hundred slides were shown by the limelight lantern.

A Committee of eight gentlemen was formed to carry out arrangements for an exhibition of photographs to be held in Newcastle next spring.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

DECEMBER 11.—Mr. Geo. Bankart (President) in the chair.

The election of officers for 1890 was fixed for the January meeting, and the lantern competition and exhibition for the commencement and end of February.

Mr. J. B. COOK then delivered an address on *Photographic Dodges*. He opened by saying how necessary it was to commence with accuracy in all manipulations, the "Dodges" being a useful adjunct. He called attention to the desirability of extreme cleanliness in dishes, measures, &c.; this he always found brought about in a most expeditious manner by the use of Brooke's Monkey Soap. Vaseline smeared on the stoppers of bottles and rubbed off again prevented sticking. For halation he found a rag dipped in methylated spirit, and the halated part rubbed with it, speedily removed to any degree. To those who found their negatives lose intensity on fixing he recommended the

addition of ten drops of ammonia to the pint of fixing bath, and he gave a practical illustration of the superiority of two buttons over the usual and conventional staples for securing the ends of the brass springs of printing frames, which prevented the shifting of the print after being examined.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

DECEMBER 5.—Mr. William Laing, jun., F.C.S. (President), in the chair.

The following were elected members:—John Foubly, L.D.S., Percy Rowden, David Bryce, W. C. Warden, W. N. Warnenke, John Pillans, George Bell, jun., William Kilstou, James Russell, and Andrew Stewart. Mr. John Mayer, F.C.S., was elected an honorary member.

After the reading of the Secretary's and Treasurer's reports, Mr. T. N. ARMSTRONG read a paper and gave a demonstration on *Transparency Making*, and this was followed by a series of slides illustrative of the various processes—albumen, Woodbury, gelatino-chloride, gelatino-bromide, collodion, carbon, Alpha, collodio bromide, &c., being shown by means of the Society's lantern.

Correspondence.

Correspondents should never write on both sides of the paper.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—I gather from Mr. Bart. Rous's last evasive reply to Mr. Durrant that he thinks it impossible for any one to reply successfully to his apparently intentionally offensive letter of November 8, in which he sweepingly condemns all my pictures lately exhibited at the Camera Club for the only qualities for which I claim any attention to them, and for which, I believe, they were borrowed by the Club. It was, of course, impossible for any one to reply to a general accusation; and when Mr. Rous is asked by Mr. Durrant to point out a few examples out of the seventy or eighty exhibited justifying his condemnations, he meanly beats a retreat by way of combination printing, on which he delivers himself of some cheap platitudes.

It is, however, not my purpose to criticise Mr. Bart. Rous; but, to prevent my motives being misunderstood, I ought to mention the other reasons, besides its offensiveness, why I refrained from replying to his letter.

In the first, but least important, place, I thought he had written it in unscrupulous, if mistaken, help to a naturalistic friend of his, with whom I had been having a little controversy in your pages, which, possibly, amused some of your readers, and did no harm. That correspondence was closed, and I did not care to reopen it. My chief reason (always excepting the intentional offensiveness) was that I happened to have heard of Mr. Bart. Rous—a distinction, I suppose, not enjoyed by many photographers; and one must draw the line somewhere, even if one does not mind drawing it very low down, and I draw it at Mr. Bart. Rous. The possession of a studio, and dating letters from the Arts Club, does not make an artist or a competent critic; and of all the shams of civilisation, the sham artist is about the most contemptible.

Mr. Rous concludes his last letter with this becoming attempt at sarcasm:—"Medals have been awarded to Mr. Robinson (and justly) for his clever photography; but I have yet to learn that they were awarded to his photographs as works of art." This may be the venial fault of ignorance, but it is more like a characteristic disregard of truth. It is, perhaps, scarcely necessary to point out to you, Sir, or to those who have followed the progress of photography, that of my one hundred medals I have never received one for mechanical photography; and that when, before medals fell in showers, Judges had time to give the reasons for their awards, they were almost always awarded to me for "Artistic Excellence," or words to that effect. I am ashamed to have to refer to this matter, but a direct untruth, even from Mr. Bart. Rous, demands contradiction.

Allow me to thank my friend Mr. Durrant for his letters on my behalf, and to gratefully acknowledge the friendship of many years at which Mr. Rous sneers.—I am, yours, &c., M. P. ROBINSON.

CELLULOID FILMS FOR LANTERN SLIDES.

To the Editor.

SIR,—With reference to Mr. W. Jerome Harrison's article in your issue of December 13, *re Celluloid Films for the Lantern*, it may perhaps interest that gentleman to know that at one of the Monday evenings at the late exhibition of the Photographic Society of Great Britain I had several lantern slides on celluloid films passed through the lantern.

The films were attached to a thick card, $3\frac{1}{2}$ inches square, with opening to serve as a mat. The result of the heat of the lantern was that, if left in over a minute, the film buckled considerably; and in one instance it broke the cardboard support, and no amount of persuasion would ever get that film flat again. Another drawback to celluloid is its slight yellow colour, which considerably mars the effect on the screen.

Your correspondent states that the films for ordinary work have one side finely ground (matt). This is not always the case, as I prefer, and have always used, in the manufacture of my films, the clear celluloid,

which gives quicker printing negatives; and the matt surface is unnecessary, as, even with clear films, there is no fear of halation.

There is no doubt that it would be a great boon if celluloid could be successfully substituted for glass for lantern slides, but I fear that that is at present impossible.—I am, yours, &c., J. DESIRÉ ENGLAND.

21, Charles-street, Royal-crescent, Notting Hill.

To the Editor.

SIR,—I would call the attention of Mr. W. J. Harrison to the fact that I have for the last year been working to produce a flexible film to be used as a substitute for glass in lantern slides, and have so far succeeded that I hope very shortly to be able to place upon the market, not only single pictures as he describes, but a series of pictures on long strips to be used in roller holders.

I have fully covered and protected the use of flexible films for lantern slides.—I am, yours, &c., WALTER P. ADAMS.

Springcell, Barnes, S.W., December 17, 1889.

A PATENTED IMPROVEMENT IN PRINTING FRAMES.

To the Editor.

SIR,—*Re* patent 16,827, published in your issue of to-day, the principle was given to the public by Mr. Z. H. Kingdon in your ALMANAC for 1887 (see p. 148), the only difference in the patented article being the substitution of hinges, which adds to the cost without affecting the result.—I am, yours, &c., KAKAREKKA.

Derby, December 13, 1889.

[We thank our correspondent for directing attention to this matter, as it enables us to say that printing frames having hinged bars and catches to fasten down the free end have been for many years in use. They are also described and figured in numerous treatises on photography.—ED.]

A LENS FOR DETECTIVE CAMERA.

To the Editor.

SIR,—In an article in your ALMANAC for 1890, entitled *How I made a Detective Camera for a Shilling*, the writer, Mr. Locke Macdonald, states:—"I obtained from Wray an excellent single uncorrected lens of five and a half inches focus for one shilling." Now the lens in question was a simple double convex of crown glass, and was intended to be used as a finder in conjunction with our 5×4 rapid rectilinear of similar focus—excellent, no doubt, as regards workmanship, but certainly not suited for use as a photographic objective.

Many, however, appear to have been misled by the term "excellent," and fancy that from us they can get a single uncorrected lens of five and a half inches focus, which, working at $f/11$ or even $f/10$, will cover quarter-plate as sharply and as well as any combination made; nay, some even have gone farther than this, and have expressed an opinion that it should give better results than an achromatic combination.

Whilst thanking those of your readers who seem to have such an exalted opinion of our optical skill, we beg to disclaim any pretensions to being able to do with one glass as much, or more, than others can do with two, three, or four.

Though the ALMANAC has only been issued a few days, we have already had numerous orders from all parts of the United Kingdom, with enclosures of from one to two shillings, for the wonderful lens; in many cases the request has been made, "Please pick me a good one;" "One that will work at $f/8$, and cover the plate sharply to the corners preferred;" and in nearly all cases what they are pleased to call a *fixed focus* is a desideratum.

This, of course, is very satisfactory in one way: it proves the enormous circulation of the ALMANAC, and we are quite looking forward to an inundation of shipping orders when it gets abroad; but in another way it is decidedly unsatisfactory, as we have to return the cash and explain that a single uncorrected lens with an aperture suited for a hand camera cannot give anything like sharp definition. A desire to prevent trouble and disappointment must be our excuse for intruding in this matter.—I am, yours, &c., W. WRAY.

Hilghate, December 18, 1889.

EMPLOYÉ'S SPECIMENS.—DRY PLATES IN SOUTH AUSTRALIA.

To the Editor.

SIR,—I should be glad to know something more about the correspondence *re* the difficulty experienced by operators in getting their specimens returned. I should like to know how they obtain them in the first place; and, considering the division of labour existing now, I cannot see how a man can say, "This is my work." If he is capable of turning out good work, his employer will naturally pay him his worth, and of course does not wish to part with a good man; but suppose the operator refuse to stay, I should like to know whether his "boss" will present him with specimens to enable him to obtain another situation; or perhaps he has already another place to go to, which he has obtained.

by or through the medium of specimens sent. It is not unnatural to suppose the operator has tried for another place before leaving the present one, but it is unnatural to suppose he has been presented with the choicest of specimens by his present employer. Now how does he get them? Is it usual for employers to present their *employés* with specimens when they are dismissed? In advertising for operators the "send specimen" is generally a part of the advertisement, and I cannot see how they are to comply with the conditions of the advertisement, seeing the difficulty of obtaining specimens honestly. I should like to hear this explained. While speaking of operators, I should like to know what is considered a good salary for a first-class operator (only)?

And, now I am writing, I should like to mention my experience with plates. I do not consider the plates sent out here equal to what they were some five years ago; either they are made too sensitive—and, as some one truly remarked, "Dry plates, like eggs, do not improve by keeping"—or owing to the reduction in prices they are now not so carefully made. Occasionally we have quite an epidemic of "pinholes," then "fog," and a very great deal of the glass is so badly scratched and full of "cats'-eyes" as to render it quite unfit for negatives. Then the "coating" is so economically done that there is nothing but a suspicion of emulsion on the plates. I have often used 300 cabinet plates in a week, and with the defects to contend with, the difficulty of doing work equal to when we had good plates (and we are expected to do this) is a task which causes us much anxiety and many thoughtful reflections on the makers.

CHARLES NEWLING.

Mount Gambier, South Australia, November 2, 1889.

A TRADE UNION.

To the Editor.

SIR,—The letter of your correspondent, "An Amateur," in your issue of the 13th instant, is certainly a most commendable production, and I am sure photographers will be most grateful for his amateurish advice. As a general rule there are two sides to every question, and I think it applies to the question at issue, and I for one, and many others that I know, consider that a Union of some description is becoming an absolute necessity; but what a disgrace to what was once a respectable profession, that such a thing should have to be mooted! Now just a few words to say why I consider it necessary. I have noticed this last few years that the wages paid to assistants seem to be worked on the sliding-scale principle—they are continually sliding down; but here the principle stops, for they never on any occasion slide up. Why is this? simply because many of the employers (I will not say all), knowing that the labour market is overstocked with photographic assistants, *meanly* take advantage of their poverty, and offer wages to first-class men hardly a trifle higher than what is paid to a bricklayer's labourer, and they, under pressure, accept the terms.

Take retouching four or five years ago, 3*l.* to 4*l.* per week was considered a fair wage for a good man, but now it is most amusing to study the muscular contortions of a photographer's face when you ask him 2*l.* 2*s.* I know a firm who get high prices, where I had the misfortune to be engaged for upwards of two years under an agreement, where 30*s.* to 35*s.* is the average wage paid, and for this was required first-class work and eight or nine large cabinet heads a-day, and treated into the bargain like so many dogs. This same firm are now paying 5*s.* for elaborately finishing 12 × 10 enlargements in monochrome, and charge their customers about 3*l.* Now is this common honesty, especially when you consider, under the present conditions of sweating, that in a very few years a man's eyesight is completely ruined?

In conclusion, I sincerely trust that Mr. Field will be successful, and that the photographic *employés* will rally round him and work together for their mutual benefit, and so upset Mr. Amateur's little scheme for tyrannising over them. Hoping some more able pen than mine will take this matter up—I am, yours, &c.,

FAIRPLAY.

Liverpool, December 16, 1889.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—I have read with much interest the letter signed "Kakabekka," hailing from Derby, in last week's JOURNAL. If he is serious in suggesting a tax and license in connexion with photography the idea is a brilliant one, and would work in several directions at once. It would elevate the "profession," by putting it on a somewhat similar footing to that occupied by the "licensed vintner."

At present it is no uncommon occurrence to find plate manufacturers and others engaged in the "trade" portion of the practice apologising for delay in forwarding goods ordered on the plea of "pressure of business." As the average amateur spoils probably a dozen plates for one used by the professional, the proposed check would cure the evil by leaving manufacturers plenty of time to attend to their customers.

The restricted demand would enable a large number of those engaged in the trade to shut up their establishments, and the labour thus set free might be diverted into other channels; for example, it might be utilised in enabling the Dock and Gas Companies to cope with the "strikes" so prevalent just now.

The demand for chemicals, &c., being greatly diminished, of course prices would go up—though we can hardly hope to go back to the "good

old times" when hypo was, I believe, sold by the ounce as a chemical curiosity—and the increased prices for materials would enable the professionals to keep up their prices, by stating truly that they had a very small margin of profit on the "finished article."

As most of the improvements in photography, say about ninety per cent., come from the amateur ranks, a wholesome check would be given to ingenuity in that direction, and the professional would be spared the necessity of keeping up with the times.

In landscape work we would be largely confined to special well-known places of interest, without having our attention distracted by admiring those out-of-the-way nooks and "beauty spots" so dear to the wandering amateur.

The amateur himself would benefit by such a tax, if sufficiently heavy to be nearly prohibitive, by being prevented from spending his money as freely as he now does on his hobby, his outlay, after the passing of the Act, being likely to be represented by shillings instead of pounds, as it stands at present.

But why confine such a "boon and blessing" to photography? There are other professions which such a law might apply to. Take music for instance. At present what house can we enter without being able to hear songs or tunes more or less ably rendered by amateurs? A heavy tax on pianos, and a severe penalty applicable to private singers who do not hold a Government license, would give professional musicians a "much-needed protection," and in time might possibly enable our prima-donnas to double the paltry sums at present demanded for their public services.

Really our Derby friend ought to give his name. In the event of such a law ever passing, it would be a pity it should remain in the list of unknown public benefactors.

JOSEPH H. WOODWORTH.

Boosterstown, Dublin, December 11, 1889.

To the Editor.

SIR,—When "An Amateur" opened the present discussion and I seconded his statements and views from a professional standpoint, I little imagined the lengths to which the matter would reach, or the innuendoes and embittered remarks that would appear. To my great regret, the majority of the writers on the subject have taken an entirely erroneous view of my opinion and statements; far be it from me to say one word against the true amateur—I am only too ready to admit the value of his services to the art science, both in the past and the present. The first paragraph of my last letter seems to have been utterly ignored by those who have attacked me tooth and nail, and to that paragraph I would now draw their attention. The views I there expressed are still unchanged, and so are those I then expressed with regard to the "amateur professional." With "M. W." I agree so far that "the harm and real injustice consists in the work being sold too cheaply." Any worker has a moral right to sell his work, but it is when he claims to work only for the love of the work itself, and under the title of "amateur" undersells the professional, that I object to him. "Anti-Monopoly" claims the title of amateur, but wherein lays the justice of that claim I leave to those who have read his letter; to those who have not I commend it as a real "tit-bit." Mr. Storey has apparently a full right to the coveted title, but, nevertheless, ranges himself on the side of the "amateur professional," and states that it is "presumption and impudence" for those who have made photography the business of their life to cry out when unfairly opposed, and advises them to "seek work of another kind," so that, after all, he is of opinion (although not expressed in so many words) that a monopoly would be all right if it were held by his side instead of the other. Mr. Victor Page's suggestion as to taxing chemicals would certainly be unworkable, while that of "Kakabekka" might be effective. As to Mr. Caldwell, I am certainly puzzled, and would merely ask if his letter is "writ sarcastic?"

The whole kernel of the matter lies in the question, Does the "amateur professional" injure the professional proper? Some of your correspondents say "Yes," and some "No." I know that if a canvass were made among the profession for their opinion that the answer would be an unmistakable "Yes." I do not intend to imply that the profession is being ruined, but better speak out when the thin end of the wedge is inserted than wait for it to be driven home, for we none of us know to what an extent the present craze might reach in a few years. If Messrs. Storey & Co. will carefully peruse the various articles bearing on this vexed subject in THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC they may perhaps be edified. Personally, I have herein said my say and I have done with the matter, my only regret being that the leading members of the profession have not been induced to speak out on one side or the other; however, I learn that the matter will be discussed at the Camera Club on the 12th proximo, when, perhaps, we shall have some more light thrown upon it. My only object in writing at all was to induce discussion and obtain the opinions of others.—I am, yours, &c.,

Windsor, December 15, 1889.

C. BRANGWIN BARNES.

To the Editor.

SIR,—It seems to me that this controversy between amateurs and professionals is becoming a very one-sided affair. I have read on this matter very carefully your valuable ALMANAC for 1889, as well as all the letters referring to it in THE BRITISH JOURNAL OF PHOTOGRAPHY, and it seems an

admitted fact among the amateurs that the whole profession is composed of nothing but the most stupid fellows, knowing nothing, but using what amateurs find. It seems to me that professionals ought to get a little credit for some improvements, however few these may be, and it is not quite proven that inventions from amateurs and professionals are not about even. It remains to be seen, also, if the photographic art in general is only kept up by amateurs, and if it were not for said amateurs that the art would be a lost one long ago.

Amateurs are very kind, and, let us admit, also very useful, but there are two very distinct classes among these as well as among professionals. Both have their artists and gentlemen as well as their cheap Johns. And now, why the artists and gentlemen have espoused the cause of the cheap Johns with such an *ensemble* is rather a mystery to me. I have no doubt but that the defendants of this cause are perfectly right when they talk of themselves and their kind, but when they take the pen in favour of the parties calling themselves amateurs and are only peddling cheapness in all the sense of the word—that is, quality of work, quality of goods, and also in regard to payment asked—I think they go too far.

I have heard of the names of J. Wedgwood, Humphry Davy, Niépce de St. Victor, &c., as mentioned in "F.'s" letter in your last issue, but I must confess I have not yet heard mention of anything about their trading faculties, nor their generous offers to take any photograph for parties cheaper than the professional. It is quite a different thing from obliging a friend or only for pleasure to take a view or a portrait, from doing this because it can be done cheaper than Mr. So-and-so can do it, and get paid for it.

As I said before, there are two very distinct kinds of amateurs. The real one, that takes his work to heart and tries to improve, and may in time invent. This kind will probably admit with me that he does not peddle his work cheap or dear, asks no pay, and does it for the pleasure he derives from it. There is then the other kind that tries to find customers, holding out only cheapness, with quality in proportion, and, willingly or not, injures soon the professional. Now, let me tell you, *these do not, and have never, nor will they ever, invent anything except ruining or trying to ruin others.* To see such men as have written lately about this controversy in THE BRITISH JOURNAL OF PHOTOGRAPHY write in defence of this class of amateurs is certainly worthy of a better cause. Nobody attacks the gentleman amateur but only the pedler. Let him defend himself if he can.

I confess that I do not see any immediate remedy to this evil, and time alone can cure this. I think also that these amateurs peddling their work for money are much less numerous than one may imagine at first, and the wrong they do is really more in their talk than their work. If they only would refrain from saying right and left that photography does not cost anything, more than three-quarters of the wrong would be prevented.

Personally, I am an architectural photographer. I have travelled a great deal, have found amateurs doing some work, but have always found architects, whatever they may have heard about cheapness in the matter before, willing to pay my price for a good view of the subject, and probably the more willingly if they were amateurs themselves.

If only amateurs selling their work would add with the price of the plates, developer, paper, and gold, also the cost of travelling and hotel when out of town, or rent, meals, &c., when at home, as well as an allowance for when no work can be done on account of bad weather or no customers, it would change materially the cost price they imagine is correct, not talking of the instruments when first class.—I am, yours, &c.,

Amitree, December, 1889.

A. LEVY.

To the Editor.

SIR,—Your correspondent "Amateur" has trotted out the lame old blackleg arguments against the "tyranny" of Unionism. I hope it will be a long time before the workmen in the trade take their policy from an amateur, especially from one whose arguments so suspiciously resemble those of the professional sweater. The little homily on women competition is proof far more positive than anything that I could have adduced of the necessity for Union in our craft. But let me assure "Amateur" that there exists fortunately a slight obstacle to the realisation of his "sweater's paradise," and it is that photography cannot be acquired "in six months." Of course, I except such photography as is "got hold of out of a book" by the great majority of the fraternity to which your correspondent by his signature declares his allegiance. For myself, I have been an humble worshipper at the shrine of Apollo for six years, and am only beginning to know how great the mystery is and what a little I know. My brother has earned his living for ten years as a retoucher, and I have never yet heard him say that he considered himself master of the art. Perhaps "Amateur's" women black—(no, Mr. Editor; like Mrs. Partington, I will not use that word before ladies, even when I only refer to table legs)—perhaps these good people, after "Amateur's" own heart, will make up in assurance what they lack in efficiency? I have no fears for the qualified and guaranteed members of our Union if the only non-Unionists they have to contend with are those with a "six months' knowledge of developing, retouching, enlarging, carbon printing, microscopic work, mechanical reproductions (zinecos, by bismuth! &c. &c.), and other processes, like the last-mentioned ones, requiring a knowledge of collodion.

And the employer of such labour would not find his path an easy one. The influence of the Union, within the law, would be brought to bear to cripple him. If it had much cash in hand it could subsidise the Trade Union houses of his opponents to undersell him, or attract custom from him by bonuses. And if a federation of labour ever occurs (and the formation of a "British Photographic Union," with instructions to aid the establishment of such a federation, would be a good means of bringing such federation to pass), no Union carter would deliver his goods, no Unionist of any trade would deal at his shop, no Union plumber, carpenter, gasfitter, cabinet maker, &c. &c., would finish any work known to be going to his establishment, or set up anything on his establishment. Promenaders would be informed by handbills that he employed only female labour, which he was practically initiating into the art, while skilled men were at the very time applying for work and being turned away. The idea would gain with the public that somehow or other his establishment could not turn out good work, and patrons could not stand the suggestions of their friends that the establishment was not a proper one to patronise. In a fortnight, by a strange chromatic phenomenon, his blacklegs would have become white elephants; he would climb down, and the *fiasco* would be complete. Ah! Mr. Amateur, it is fortunate for society that all men are not so courageous as yourself.

[May I here thank "G. B." for his communication? I will make good use of the information.]

Thanking my correspondents, and asking all interested to send stamp for particulars—I am yours, &c.,

ARTHUR G. FIELD.

Maidstone, December 17, 1889.

To the Editor.

SIR,—In your JOURNAL of the 6th instant there is a letter from "F." which made me rub my eyes. He there states that all the improvements in photography were made by amateurs, and "given free to all men."

I really think such a statement ought not to be made without contradiction. Certainly, neither Daguerre nor Fox Talbot gave their discoveries free, as they both took out patents, and Beard, one of Daguerre's licensees, who was among the first professional photographers, made many improvements, which he also patented.

I am not quite sure whether Scott Archer was an amateur or professional, but when he introduced collodion Fox Talbot considered it an infringement of his process, and entered an action against some person for using it. The action was decided against Fox Talbot. I thought this decision was not quite just at the time, and think so still.

The use of gelatine for making dry plates, both with and without collodion, having been known so long, and the improvements made in it so gradual, may account for its never having been the subject of a patent before the orthochromatic patent.

All the other great improvements, whether discovered by amateurs or professionals, have been made the subject of patents. Mr. Pouncey, a professional photographer at Dorchester, made the first permanent photograph in carbon. The autotype, the Woodburytype, and the platinotype have all been protected by patents; and when we find that more than 200 patents have been taken out for improvements in photography and photographic apparatus during the last twelve months, it does not appear probable that any improvements will be given "free to all men" in the future, either by professionals or amateurs.—I am, yours, &c.,

Bath, December 16, 1889.

J. DUTTON.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange exterior background, good as new, for interior or conservatory ditto.—Address, E. PENFOLD, 106, Union-street, Turku.

Will exchange quarter-plate Instantograph, 1889, and cash, for half-plate International or Instantograph.—Address, THOMAS MOILES, West-street, Midhurst.

Large-size tracing machine and a pocket pistol will be exchanged for half-plate camera, lens, and dark slide.—Address, W. G., 16, Bartholomew-house, Bartholomew-close, E.C.

I will exchange cabinet burnisher, also first-class C.D.V. portrait lens, for backgrounds or accessories. Address, W. WALKER, 156, Noel-street, Nottingham.

Will exchange photographic and mathematical instruments for English and American coins in good preservation.—Address, W. ETHELBERT HERR, 49, Melbourne-street, Derby.

I will exchange two plaques, decorated, fifteen inches diameter, Minton's manufacture, and two pieces of pottery, for a good second-hand half-plate or quarter-plate camera.—Address, H. SPILSBURY, 3, Berry-street, Stoke-on-Trent, Staffordshire.

Four thousand four hundred Gem and Victoria mounts, half of each, in exchange for whole-plate or 10x8 lens; whole-plate burnisher in exchange for head and body rest, or posing chair.—Address, H. T. AULT, Photographer, 19, George-street, Newcastle-under-Lyme, Staffordshire.

James's triple flash lamp (good as new), Guerry's shutter for studio, and Cowan changing box, for 10x12 plates; wanted, 12x10 and 8x6 printing frames, optic lantern, &c.—Address, JOAN DAVIS, 34, Cambridge-road, Barking, Essex.

I will exchange a mahogany dissolving-view lantern, four-inch condensers, gas bag, pressure boards, and about one hundred slides, sixteen-feet screen, &c., for a harmonium or tricycle to value.—Address, PHOTOGRAPHER, 27, Plinington-road, North Preston.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

W. W. Stainthorpe, Kirkleatham.—*Photograph of thrush feeding its young in nest.*
J. Ashley, Liverpool.—*Two photographs of Mr. Parr Davies.*

PRINTS.—Apply to Goupil & Co.; they are the owners of the copyright of the works you require.

J. W. (Ipswich).—The trade methods employed for making bromide paper have not been divulged.

E. R. P.—The shutters are made of millboard. This may be obtained from any wholesale stationer or bookbinder.

J. FOSTER.—Order a guide to Jersey through any bookseller. You will not experience any trouble with your plates when passing the Customs.

JOYCE.—Not having had any experience similar to yours, we cannot indicate the cause. Try another formula for the developer; you will find plenty in the ALMANAC.

S. G. R. J.—We cannot tell the cause of the stains. It looks in one instance as if some of the colour of the mount had been dragged by the burnisher over the edge of the print.

LANTERN.—There is nothing better than ordinary flour paste as a cement in binding the edges of lantern slides. Gum and gelatine are liable to cause the paper to peel off when long subjected to heat.

W. RAY inquires whether the Ordnance maps are printed from "photo-zinc" blocks or by the zinc process, which is analogous to lithography.—The maps are printed by photo-zincography, and not from surface blocks.

C. WILSON.—To use a still a ten-shilling annual license is necessary; but this does not entitle any one to purify or deodorise methylated spirit. This is prohibited by law, and its infringement entails very heavy penalties.

BRONZE MEDAL.—To master Aristotype printing, it is only necessary to adhere to the directions given by those who sell it, and exercise common judgment. There is no greater difficulty in it than in printing on albumenised paper.

W. V.—Probably the carbon tissue is at fault, as it may be after some years' keeping. To test this, place some of it, before it is sensitised, in warm water, say at 100°. If the gelatine will not dissolve, the tissue is worthless.

A. B.—It is only when water contains chlorides or carbonates that a milky appearance is produced when washing prints prior to toning. The milkiness, or otherwise, of the water makes no difference as to the permanence of the prints.

G. CONSELL.—There is no paper made in England which is suitable for photographic purposes; that is, for ordinary silver printing on albumenised paper. This seems almost a reproach on British paper makers, but it is a fact, nevertheless.

A. MONTAGNA.—1. The Stannotype Company is not now in existence. The necessary materials may, no doubt, be obtained from M. Liesegang, Düsseldorf, Germany.—2. About twelve or fifteen inches.—3. The results by the two processes are very similar.

B. B. A.—The yellowness of the prints is due to imperfect fixation. Either the fixing bath was too weak, or the prints were allowed to stick together so that it could not act freely. From the yellowness being in patches there is little doubt but the latter was the cause.

W. J. C.—We are not at all surprised that you have been unable to obtain eikonogen at ordinary chemists. Had you applied to any other dealers in photographic materials you would have been more successful. Messrs. Marion & Co. are the wholesale agents.

CR. PRINT puts the following query: "After taking the prints out of the washing bath, how can I dry them so that they will lay nice and flat, as I do not want to mount them? They are the ordinary silver prints."—Place the prints between blotting paper and allow them to remain there until they are perfectly dry.

WILLOTT (Maldon).—It is very unlikely that the water contains nitrate of potash; even if it does that will not interfere with the removal of the silver. Hydrochloric acid would be very objectionable in the bath. The yellowness is due to imperfect fixation. The bath is too weak. Use four ounces of hyposulphite of soda to the pint of water.

C. LAWRENCE.—By all means avoid bronze-printed mounts if you value your reputation. There is no harm in gold lettering, but, of course, gold-printed mounts are much more expensive than those printed with bronze. If price be an object, why not be content with ordinary ink?

HERTS.—An ordinary lantern, with a good paraffin lamp, will answer very well for enlarging on bromide paper. Of course the exposure will be dependent upon the amount of light and the density of the negative. A few trials on small pieces of the paper will overcome the difficulty of exposure.

W. G. CLEMENTS.—The enclosure is magnesium ribbon. Place the ground glass about an inch behind the negative, and, having ignited the magnesium, move it across the surface from one side to the other. Experiment will enable you to determine the proper length of ribbon to employ.

C. R. R.—With a lens of seven inches equivalent focus you will not be able to take full-length carte portraits in a studio only fourteen feet long. Such a lens, however, will answer quite well for three-quarter and bust pictures. Cannot the length of the studio be extended with the proposed alterations?

HERBERT W.—1. Coat the plates with collodio-chloride of silver emulsion if you want to print by contact.—2. We believe both photometers are good. We should advise you, however, to learn to judge of the exposure without the aid of photometers. We should never think of using such things ourselves.

SARUM writes: "Having saved the old hypo fixing baths for several months past, I a few days ago added some potassium sulphide, as per instructions given in the article on residues in the JOURNAL of July 26, which I have read over several times. Now what I am uncertain about is whether enough sulphide has been added, for on dropping a few drops into a glassful of the turbid hypo solution I could not see that it became any clearer, but perhaps rather the reverse. The vat of solution has since the addition of the potassium settled and become quite clear. Is this any test that all the silver has been precipitated?"—The fact that the precipitate has subsided, and the supernatant liquor has become clear, is no proof that the whole of the silver has been thrown down. If the addition of more sulphide to a little of the clear liquid produces no further turbidity, the whole of the silver has been precipitated.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Mr. N. P. Fox having resigned the Secretaryship of this Society, Mr. G. J. Clarke, 52, Queen's-road, Brownswood Park, N., has been elected to the office.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—This Society has made arrangements to hold an international exhibition of photographs and apparatus in the Art Gallery, Newcastle-on-Tyne, from April 18 to May 3, 1890, when the Association intends offering a number of medals for competition in various classes.

THE TERRORS OF A THEODOLITE.—Pathans, as may be supposed, are not familiar with the theodolite and flag of the surveyor. But at Kilah Abdulla, beyond Quetta, the Madras governor's party found that a frontier surveyor busily at work was the victim of a terrible suspicion. The Pathans, he said, believed that the theodolite was a kind of photographic camera, and, like the camera, it took pictures upside down. More than this, they think a person using the theodolite can see through the walls of houses, with the appalling result that the ladies of their families are photographed by the infidel standing on their heads. It is not surprising, therefore, to hear that the surveyor is highly unpopular, and is apt to be shot at.

PHOTOGRAPHY IN COURT.—McKellan v. Jowett.—In this action Mr. Eastwood appeared for the plaintiff, Mr. Samuel Dunseith McKellan, of Hulme, Manchester, who is a dealer in photographic apparatus and the patentee of two improvements in the manufacture of photographic cameras, who sought to obtain an injunction to restrain the defendant, Mr. Arthur Jowett, who is also a dealer in photographic materials, carrying on business at Romiley, from manufacturing, exposing, or selling any cameras similar to those of the plaintiff, made under the specifications of his two patents, and, further, for an inquiry as to damages. The plaintiff also asked for an order for the delivery up of a particular camera, now in the possession of Mr. P. Harris, of Stretford-road, Manchester, which was alleged to have been sold by the defendant and to be an infringement of the plaintiff's letters patent, and for the costs of the action. The defendant, in order to save further expenses being incurred, did not appear, and there was no defence to the motion. The Vice-Chancellor, therefore, made the order as asked for in the notice of motion.

* * As we go to press much earlier next week than usual owing to Christmas, all communications to the Editor must be received not later than Monday morning.

No. 1547. VOL. XXXVI.—DECEMBER 27, 1889.

A MYSTERIOUS LANTERN SLIDE.

STRICTLY speaking, it is not one but a series of slides which form the theme for these remarks.

A few weeks ago we received a parcel of French lantern slides from a correspondent, who informed us that they formed portion of some which he had taken with him to India, where they had been for two years. Observing that they had gradually been becoming somewhat obscured by a species of mistiness, he undid the binding of one of them with a view of wiping off the scum which seemed to have settled upon the covering glass, when he found that all the area not protected by the mat had become corroded. Only those slides of French manufacture were thus effected, those of English make suffered no change. Curious to know the cause of this erosion he sent them to us.

Upon removing the binding and opening up some of these, the covering glass, where unprotected by the mat, presented a finely dimmed appearance, not so coarse as even the finest ground glass, but as if breathed upon, or as if it had been exposed to the fumes of hydrofluoric acid. The extreme fineness of this elicited from friends to whom it was shown warm expressions of desire that such could be obtained in sheets for focussing screens for cameras. Indeed so fine was it, that some at first considered it was only a scum of the nature of a varnish, which could be removed by scraping with a knife, especially as such scraping did remove a dusty deposit from the surface, only, however, to reveal the fact, under the microscope, that the dust was disintegrated glass, and that the surface below was eroded. We had previously applied to the glass quite a variety of solvents of gums, including alcohol, ether, chloroform, and benzole, without any action being apparent. The image on the slide having been formed on albumen, we were quite at a loss to account for the liberation of any corrosive, such as hydrofluoric acid—the only one we could then think of as capable of having an action of this nature on glass.

As it was somewhat of a puzzle, we showed it to opticians, experts in glass burning, and others likely to throw light upon the subject, but without avail. Knowing that the singular beauty of many of the French slides depends upon their being toned with mercury, we casually mentioned this when bringing the subject before the meeting of the London and Provincial Association on Thursday last week, and a clue to the difficulty was suggested by Mr. Everett, one of the members. Mercury, he said, was well known to attack glass, presumably from its affinity for lead.

Following up this idea, we think a valid cause of the disintegration of the glass is to be found in the fact that mercurial vapour, liberated from that imbedded in the interstices of the image by the heat of India, operated upon the glass and decomposed it. We have obtained numerous formulæ employed by French glass makers in the manufacture of glass of a nature similar to that made use of in covering lantern slides, and we find that not only lead but arsenic and other metallic substances form component parts of the same. We here give as a specimen formula one of these employed in actual practice:—Sand, 110 lbs.; oxide of lead, $49\frac{1}{2}$ lbs.; potash, $39\frac{1}{2}$ lbs.; arsenious acid, 1 lb. Why slides of English manufacture should have enjoyed immunity from the erosion spoken of it is difficult to say, unless there is some difference in the composition of the glass, or perhaps there is no mercury employed in the toning. We have known innumerable instances in which the image on the slide has itself faded as a result of this toning, even when it was protected by a varnish possessing a good body, but in this case it was probably washed in an imperfect manner. Heat, at any rate, was not a factor in the destruction, as several of the slides in question had never even been subjected to even the heat of the lantern; but never before have we known of a corroding action on the cover glass such as that described. The action of moist air we all know exercises an action upon optical flint glass, especially that of French manufacture, as most persons who have taken opera or field glasses to India are but too well aware, the action showing itself in the form of a brown stain on the flat side of the object glass. This is sometimes, too, the case with photographic lenses, although, happily, it is of less frequent occurrence, owing perhaps to the fact that photographers in hot, humid climates probably keep the lenses of their photographic objectives cleaner than they do those of their binoculars. In every case we have seen, it is the flint glass of the achromatic lens that has suffered from atmospheric causes.

It is probable that some of our readers may possess knowledge of the erosive effect produced on glass by the vicinity of mercurial vapour—assuming such to have been the true cause in the case we have adduced—and, if this be so, we shall gladly welcome any hypotheses as to the nature of the action. Fortunately the remedy is not difficult, as it consists in supplanting the eroded cover by a new one. In the meantime the possessors of French transparencies, whether for the lantern or the stereoscope, which have seemingly become dimmer by the joint actions of time and a high degree of

temperature, should, before looking upon the images themselves as having succumbed, ascertain whether the fault does not really lie with the covering glass.

PHOTOGRAPHY AND THE SOLAR ECLIPSE OF DECEMBER 22.

On Sunday last, December 22, one of those comparatively rare events—a total eclipse of the sun—took place along a band extending from Western Africa to the West Indies. Two small expeditions have been sent from England to observe the phenomena, which, it was hoped, would be visible. The first of these is under the direction of the Rev. S. J. Perry (whose able address on "The Photographing of the Heavens" will long be remembered by those who had the good fortune to hear it at the Birmingham Convention of 1888), and has been stationed at Barbados in the West Indies; the second expedition is in charge of Mr. A. Taylor, and has been stationed at or near Loanda, in West Africa. Each observer took with him a reflecting telescope (silver-on-glass mirror) of twenty inches in diameter (these being the largest instruments ever used for such work), fully equipped for photographing the eclipse. These mirrors, with their mountings, have been made from designs specially prepared by Ainslie A. Common, Esq. Their focal length is only forty-five inches; so that, as a diaphragm fifteen inches in diameter is employed, we have a focal aperture of $f/3$.

The objects of the expeditions have been three in number, all depending mainly on photographic operations for a successful result.

1. To detect any possible changes in the corona during the two hours and a half that elapse between totality at Loanda and at Barbados.

2. To photograph the coronal extension as far as possible from the sun.

3. To determine the photometric intensity of the corona.

The eclipse remains total for 186 seconds at Loanda, and for 135 seconds at Barbados. Five plates were to be exposed with the mirrors during this brief period at each station, the exposures being 1, 5, 10, 20, and 40 seconds respectively.

The following developer has been suggested by Captain Abney for developing the plates:—

- | | |
|----------------------------|-----------------------|
| 1. Pyrogalllic acid | 2 grains. |
| Water | $\frac{1}{2}$ ounce. |
| 2. Potassium bromide | 20 grains. |
| Water | 1 ounce. |
| 3. Ammonia (880) | 1 part. |
| Water | 9 parts. |
| 4. Sulphite of soda | a saturated solution. |

To No. 1 add two drachms of No. 2, thirty minims of No. 3, and two drachms of No. 4. Add water to make up to two ounces.

Reducing this developer to its simplest terms, we find it to consist of—

- | | |
|-------------------------|------------------------|
| Pyro | 1 grain, |
| Ammonia | $1\frac{1}{2}$ minims, |
| Potassium bromide | $1\frac{1}{4}$ grains, |
| Water | 1 ounce, |

with enough sulphite of soda to prevent discolouration. It is evidently a developer well calculated to bring out contrast, and that was doubtless the work for which it was designed, the object being to differentiate between the light of the extreme parts of the corona and the almost equally intense light of the

surrounding sky. We would suggest that the mixture given above be known as the "Eclipse Developer."

The observers had some practice with their instruments before leaving England, and with the twenty-inch mirror Mr. Taylor secured a photograph of the "earth-shine" on the crescent moon, giving an exposure of three minutes. The nebulae in the Pleiades required an exposure of thirty minutes.

As expeditions from the United States have also been sent to observe this eclipse, we feel confident that, granted a clear sky, much additional knowledge as to the nature of the corona and other solar envelopes will be obtained.

PHOTOGRAPHING INTERIORS.

CONCLUSION.

THE expedients narrated will usually minimise the evil effect of strong illuminated skies causing halation effects, but window lights must be considered as affording other troubles. Important among these is the illumination of the atmosphere of the interior of a spacious building, as, for example, a church. When a long vista with interesting details at every point, a sun-light atmosphere is ruinous to good work, excepting only when the visible path of the sunbeams or the object they strike upon aid in the pictorial effect the whole scene produces. Then, if the slanting rays be not very wide, very pretty effects may be secured; but this is comparatively rare, and the consequence is that when public buildings and places of worship are the objects of the camera, the best effects are far more easily obtained in late spring, summer, and early autumn, where the haze to be illuminated and produce fog is generally almost entirely absent. This haze is a very serious question as much indoors as out, for in the winter months, with fogs and extra smoke, the days out-door or in that fine negatives can be taken are wont to be exceedingly few and far between. In this connexion let the photographer remember that by choosing the time of day he takes the view he may frequently eliminate any injurious effect the sun's rays might produce by waiting for the luminary to "go round," and so send his rays at such an angle that they are scarcely seen. It should suffice here to remind the reader that he can easily ascertain this by remembering that the communion table is almost universally placed at the east end. Again, too, if the sun cannot be thus evaded, the least degree of foginess is produced the more it lies in the direction of the photographer's back. Facing the rays end on, as it were, we get fog; looking along them, their source being behind, the fog is reduced to a minimum.

Then, again, as to windows it is very far from always being the right thing to use all the illumination possible. For interiors a very considerable range of effect is obtained by entirely or partially cutting off the light from one or more, and, sometimes, great improvements in the general effect, the chiaroscuro of the picture. We have, as we write, two views of the same apartment taken by two different photographers: in one the foreground is brilliantly illuminated by what is evidently a large window, in the other the window has been curtained over. The difference in effect of the two pictures must be seen to be appreciated.

The subject of windows or other illuminating orifices would take long to exhaust, but we will leave them in pointing out a most important effect for consideration. It very frequently happens that the camera itself is placed in the full light of the window, while the apartment to be photographed is but dimly lighted, and long exposures will be required. The best con-

tion will then be present for fogging the plate: the lens must be screened. If the camera possesses no screen of its own, some extemporised arrangement must be made. The dark cloth may be brought forward, or some object, such as a step ladder with cloth thrown over placed between camera and light. Light must not be permitted to fall upon the lens, for if it be, crisp negatives will not be obtained. A very awkward position sometimes occurs when the object to be photographed, say the high altar in a cathedral, is just below a window. We repeat the lens must be screened, and in this case the screen may have to project a considerable distance forward; and it is most strongly to be impressed upon all who are unfamiliar with this work that our remarks on this head are of the greatest importance.

It may not here be inopportune to point out that the arrangement of the furniture of a dwelling room plays a most important part in the pictorial effect. The removal of a piece of furniture—a chair, a table, or even an ornament on a table—an inch or two in one direction or another may make all the difference between a pretty picture and an awkward-looking map of a room. Foreground is most important; this, of course, is always the case, and is of prime importance in the photograph of an apartment full of furniture and knick-knacks. And here, no matter how experienced a hand the operator may be, it will generally be found necessary to refer to the ground glass to observe the effect; indeed, it would be well to have some one to shift the furniture to the dictation of the artist at the ground glass. Those who have not done much work of the kind will be astonished how important is the attention to these matters. But a word of caution: though pictorial effect is an important consideration, the propriety of things must be borne in mind. If a room be of the nature of an ante-room, for example, it would never answer to block up the obvious path for the sake of making the object balance or fill up bare spots. And, once more, some ladies have most particular notions as to the exact spot for each particular piece of furniture, and if her views be ignored the result might be for the picture to be returned upon the hands of its producer.

Finally, we have to consider the plates themselves that are fittest for the purpose. We have already spoken of backing them; now we have to say that the general consensus of opinion is that slow plates are far the best for indoor work. With quick plates it is often considered that with such contrasting depths of shade and varieties of colour from white to black, greyiness is apt to be produced with the quicker plates. Whether this be the case or no, we do not offer an opinion.

We have now treated the subject from standpoints sufficiently numerous to give the tyro many useful hints, and perhaps the older hand may be benefited by some of our remarks on this interesting kind of work—the photographing of interiors.

FREQUENTERS of the leading London thoroughfares do not require reminding that, since the recent legislation on the subject of electric lighting, the different Companies have not been idle. Indeed, their activity has, in many instances, been a source of considerable inconvenience to pedestrian and vehicular traffic. It is certainly a wise precaution that the leads are underground, as there they will be less dangerous, also less liable to injury, than if they were overhead. In some instances insulated leads are laid in metal tubes, in others bare metal conductors—bundles of stout copper bands are simply laid in tubes of an insulating material. In America, according to the newspapers, there have recently been several fatal accidents through overhead leads which were but imperfectly protected; also some serious

conflagrations through faulty internal appliances. Such accidents may be avoided with underground mains, and more attention to the fittings. As a rule, the current is supplied in a dangerously light state of tension, and is then reduced by a transformer to suit the necessary conditions. The extension of the electric supply will be a great convenience to photographers, as there are, or shortly will be, few localities in London, or other large towns, where the electric light will not be as available as gas. Then, there is little doubt, the light will be still more extensively utilised for photographic purposes.

THERE are photographers in London, who a few years ago went to the cost of dynamos and engines for generating the current and have since discarded them, now taking their supply from the mains. From this source the current is always at command, and is available at a moment's notice. Unfortunately there is not, at the present time, an electric meter which is thoroughly satisfactory in practice. However, most of the Companies have a contract system with regard to incandescent lights—so much per light per year. With the arc light, which is only used by photographers at uncertain intervals, the charge is based by some Companies upon the consumption of the carbon rods, these, of course, being supplied by the Companies. Till the adoption of a satisfactory meter, this is a very equitable arrangement.

THE enforcement of the Merchandise Marks Act reveals the not altogether pleasant fact that by far the larger proportion of the Christmas and New Year's cards sold in this country are printed abroad, as the imprint upon them testifies. A large number of collotypes used to be printed in Germany and passed off here as being of home production; but a considerable check has been put upon this trade by the vigilance of the Customs officials, who, now, will not permit them to pass unless they bear an imprint showing the place of their production. Still, however, the Act is being evaded in photo-mechanical work.

It may not be generally known that a considerable number of the "process blocks" and photographically engraved *intaglio* plates used here for book and periodical illustrations are made on the Continent, though printed from here. These blocks and plates, or the prints made from them, bear no indication whatever that they were made abroad; hence they are supposed, by the uninitiated, to be of English production. Although foreign work may be as good as, or better than English, it does not appear of so high a value in the eyes of the British public. If all foreign-made plates had to bear an intimation as to the place of their origin, they would not be so largely employed by many first-class publishers as they are at the present time. Many fancy cards and books bear the imprint "designed in England, printed in Germany." Why should not photographic engravings be marked "engraved abroad, printed in England?" There can be no valid reason why the Merchandise Marks Act should be put in force with regard to prints, while it is not enforced in the case of the plates or the blocks themselves.

It will be remembered that some time ago considerable indignation was aroused in this country by reports stating that an execution was suspended, after the unfortunate culprit had been pinioned and everything was in readiness, in order to give a photographer time to arrange his apparatus to secure an instantaneous photograph of the event. Several highly sensational articles appeared in some of the daily and weekly papers on the barbarity of the proceedings. It now appears, from a letter from Mr. Stanley, dated from Lake Victoria, that the report had no foundation whatever; in fact, that at the time of the execution there was no photographic apparatus within five hundred miles of the scene. Photography is here exonerated from the charge of having been put to a most inhuman purpose, and the whole affair proved to be a "much ado about nothing."

THE shortest day is now past, and from this time the duration of daylight will gradually extend. As a matter of fact, however, it is noticed by photographers that the light is usually not so good in January as it is in December or November. A London portrait

photographer recently remarked to us that, as a rule, we have more "November fogs" in January than we do in the month to which they are credited. Anyhow, in London this year November fogs were conspicuous by their absence. Whether they will make their appearance later on remains to be seen.

ARTIFICIAL light—so far as the flash light is concerned—is not being so much adopted by professional photographers as it was at one time predicted it would be. However, amongst amateurs during the festive season it will not be overlooked, and many and interesting, as well as amusing, pictures will no doubt be produced. In taking instantaneous pictures by the flash light considerable discretion should be used. An instantaneous photograph taken while a little harmless fun is proceeding may be, and we regret to say has been, turned to a very unpleasant account.

THE present is about the time when photographers collect their year's residues and turn them to account. Many will do well to refer to the articles on *Economy in the Printing Room* which recently appeared in these columns before commencing operations. The desirability of reducing all the residues to the smallest possible bulk by complete burning in the case of paper, and by thorough drying in the case of the chlorides and sulphides, should always be borne in mind. Also, that as much extraneous matter as possible, which contains no silver, should be removed before sending to the refiner. When this is done, trouble and expense is saved in the reducing.

LANTERN IMPROVEMENTS.

APPROPOS of some lantern literature we have received from Messrs. Perken, Son, & Rayment, we perceive that this firm has introduced a novelty which is one of great value, namely, that of interchangeable condensers in their enlarging lanterns. In order to utilise a half-plate or a whole-plate negative in the production of a picture of larger dimensions, it is imperative that the diameter of the condensers in the enlarging lantern shall exceed in a slight degree the diagonal of the negative, or its measurement from corner to corner; and the condenser for the larger size is, from its longer focus, far from being so well adapted for the smaller negative as one specially constructed for that size. The difficulty may in some measure be met by having the negative carrier fixed to a travelling base, so as to permit of a negative of relatively small size being moved forward in a large cone of light, so as just to be covered by the light and no more; but this is only an expedient, and one for which no provision has ever been made in enlarging lanterns, at least in none which we have seen.

But by having the condensers set in a wooden frame capable of being inserted in a properly grooved recess in the body of the enlarging lantern all trouble is at an end, and this is the idea that finds practical expression in the new Optimus enlarging lantern, of which we here give a drawing. By having only one enlarging lantern, and

two or more condensers of different diameters, it is evident that the enlarger is placed on a footing similar to the possessor of a camera that has facilities for holding plates of different sizes with lenses to suit each. Nay, more, for by discarding entirely the use of this lantern as a photographic enlarging apparatus, and inserting in the adapting frame a condenser of small size, by which we here mean one

of four inches diameter, it is evident that we now possess a projected optical lantern pure and simple, and not a mere makeshift at all, but one which fulfils every optical and mechanical requirement. For this reason we are much pleased to be able to record what is a decided improvement upon a useful piece of apparatus.

In the construction of the ordinary optical lantern we may direct attention to what we consider is also an improvement upon the time-honoured instrument of this class—it is found in the inserting of slides from above rather than in the pushing of them in from the side. This latter method is, doubtless, indispensable in the case of a succession of slides being "passed through the lantern," as the common phrase runs, but it interposes a serious difficulty when manipulating the chemical or life tank, of which we give a view in the adjoining cut.

This may contain small fish, large aquatic beetles, or any of the innumerable objects known as photographic life, or it may contain chemicals or crystallisable compounds acted upon by other chemical reagents, or by the electric current. It may contain an exposed plate, the development of which is to be shown upon the screen to a large number of spectators. The lantern shown in the cut, in which the objects are inserted from

above, indicates the best way in which the tank is to be inserted.

We are much pleased to find that Messrs. Perken, Son, & Rayment have provided the photographer with so much that conduces to success and enjoyment and the real instruction and amusement of the public in their enlarging and projecting lanterns.

SENSITOMETRY IN TWO CHAPTERS.

CHAPTER II.

BEFORE alluding more directly to the mechanical department of sensitometry, I may perhaps be allowed to revert shortly to the mention in the preliminary report of the Congress of the method of gauging the results obtained and the means proposed for obtaining them.

It is not perfectly clear what the report really means in speaking of the renunciation of methods of measurement "by means of special apparatus" on the ground that these "measure only the functions of the sensitive substance and of the apparatus employed." We are compelled to employ some form of apparatus, preferably such as will measure the "functions of the sensitive substance" rather than our own. After alluding to the complications introduced by the variations in development, the report goes on to recommend a system of comparison of the tints obtained by development with a series of artificial or mechanical tints formed by black hatchings on a white ground. Surely no method of comparison could well be much less satisfactory than this, yet it is difficult to fix on a really satisfactory one; and as undoubtedly the matter received due consideration before the report was issued, we are brought face to face once again with the difficulties of the subject on the mechanical side.

From the purely mechanical point of view we have specially to deal with the sensitometer proper, that is, the apparatus employed for the purpose of actually measuring or graduating the light allowed to fall upon the standard sensitive surface. As I have already pointed out, existing instruments fail in the requirements, inasmuch as they present no definite series of gradations or tints; for though the

may be useful enough for special purposes and in the hands of those who are thoroughly conversant with them, it is not possible to state in accurate terms the relative values of their different tints. Thus the various forms of photometer or actinometer in daily use in connexion with carbon printing and similar processes, consisting of a scale of tints or steps of gradually increasing opacity, behind which a strip of sensitive silver paper is exposed, though practically useful and thoroughly intelligible to those who constantly employ them for the purposes named, are of little or no use in other hands or when otherwise applied.

By actual experiment it is ascertained how many thicknesses of paper or other translucent material forming the screen are penetrated by the light necessary to properly impress the tissue when printing from a certain negative, and this once found proves approximately correct with the same negative in all variations of light. But it is impossible to say that the readings carry any meaning to one unacquainted with the instrument, or that the absolute value of the exposure given can in any way be calculated.

In the Woodbury photometer, which is much used for similar purposes, as well as for roughly estimating the value of the light when making camera exposures, the system is different, but still subject to the same objection. In this a central aperture of clear glass is surrounded by a series of tints painted to imitate silvered paper in various stages of darkening, and a strip of sensitive paper being exposed through the clear aperture for a given time is compared with the surrounding tints, and that one selected which most closely resembles it. Here, again, the reading is purely arbitrary, and possesses no value except to those who have had experience with the instrument; while the accuracy of the estimation is still further lessened by the possible variation in colour between the sensitive paper and the painted tints. The actual colour taken by albumenised paper under the action of light is modified, as is well known, by many circumstances: by the salting of the paper, the length of time it is floated on the silver bath, and the strength of the latter, as well as by the character of the light employed, so that here again it would be folly to say that any definite measurement is obtained of the light used.

In Warnerke's sensitometer the different tints of the graduated screen have been arranged with the utmost care in order that they may, as far as possible, bear a definite relation one to another, and it is usual to consider them as having such proportionate values that each alternate tint represents a double exposure. The screens or scales are made by the Woodbury type process, and consist of a cast in coloured gelatinous ink from a plate presenting hollows of gradually increasing depth. It is of course possible, working with one standard, with the same batch of ink and with an absolutely uniform pressure, to produce a series of screens which shall be identical, but it is, to say the least, extremely difficult, even in the hands of the same operator, to secure these conditions. In the first place, the slightest variation in pressure produces a corresponding difference in the quantity of ink left in the mould, consequently an entire modification of the whole scale, and in order to avoid this result we are met with the additional necessity for the employment of glass of absolutely uniform thickness as well as mathematical accuracy of surface. Further, the temperature of the ink must remain constant, or a similar variation in the quantity remaining in the mould will be the result, from which it may be gathered that, even adopting the most stringent precautions, the same individual will find it no easy matter to produce uniform scales.

When, however, the work is executed by different operators from different plates and with different ink, it is impossible to imagine that anything like uniformity can be attained, and this alone prevents the Warnerke or any other screen consisting of varying thicknesses of semi-transparent matter of whatsoever nature from being accepted as a universal standard. Such may be useful for individual purposes, but no more; and it is no doubt such contrivances that the promoters of the Congress had in view when in their report they deprecate the use of special apparatus.

To Mr. Alexander Cowan, so far as I am aware, belongs the credit of having first pointed out the conditions necessary in a universal method of measuring sensitiveness. His proposition, made nine or ten years ago, was to employ a falling shutter immediately in front of the sensitive surface, the shutter to be pierced with a series of open-

ings varying in length but bearing a definite relation to one another. Mr. Cowan pointed out the importance of being able to measure *by time* the actual exposure given to some standard light without the intervention of any translucent or semi-opaque material between the light and the plate. These two conditions I hold to be absolutely essential, and though Mr. Cowan's apparatus would be but limited in its utility, still I repeat the credit is his of having shown the direction in which to work.

Ignoring *vis inertia* and friction, the speed of a falling body is readily calculated by known rules; but taking them into consideration, the difficulty of accurately timing such a shutter as that proposed would be very great, while the range of exposures possible without very cumbersome apparatus would be comparatively small. Still, for some purposes such an apparatus presents advantages over any of the artificial screens.

Somethirteen or fourteen years ago Captain Abney described a method of producing an evenly graduated tint on a photographic plate for photometric purposes, dispensing with the use of different thicknesses of superimposed paper or other translucent material. This consisted in causing a star, cut out in blackened tin or cardboard, to revolve rapidly in front of a white background and photographing it while in motion. Clearly the central portion of the "star" would be rendered black, the tint gradually and imperceptibly becoming lighter until the pure white of the background was reached, and by cutting out a strip from this vignette a delicately graded tint would be obtained which might be varied to any extent by modifying the outlines of the star.

On this principle was based the proposal for a sensitometer which Mr. Bedford and myself, independently of one another, communicated to the Photographic Club some years ago on the same evening, and which has since been elaborated for experimental purposes. Roughly, this consists of a disc of thin metal or other material mounted upon an axis and capable of being set in rapid revolution. It is plain that if apertures of varying angular measurement be cut in this disc at different distances from the centre the disc when revolving will cut off varying proportions of light from a sensitive plate placed behind it and in close proximity; and these apertures may be so proportioned as to be definitely related to one another, while at the same time giving accurately timed exposures or subdivisions of a more or less protracted exposure.

Thus, if the disc be divided into a series of concentric zones, and commencing with the outer one a portion representing six degrees of arc be cut away, and with each succeeding zone the excised portion be increased by six degrees, when set in rapid motion a series of exposures will be given to a plate placed behind it and uncovered for one minute, varying from one second upwards by seconds, since the smallest opening of six degrees represents one-sixtieth of the total period, the plate is allowed to remain uncovered. The result on development is a series of concentric bands of correspondingly varying intensity, more or less sharply defined according to the distance between the sensitive surface and the revolving disc. Or a series of points may be marked at regular distances from the centre, and representing gradually increasing angular measurements from a radial line. If these be joined in a rough curve, and the portion of the disc between the curve and the radius be cut away, an evenly graduated tint will result instead of a series of abrupt ones. Still another alternative consists in drilling a series of holes of uniform size at regular and calculated distances from the centre, when the image on development will consist of a number of concentric lines of varying density separated by bands of clear glass. In each case it is easy to calculate the exact period of actual exposure that has been given to any portion of the plate.

Such a piece of apparatus, while admirably adapted as a basis to work upon, giving as it does the absolute power of subdivision of a comparatively long exposure, is better adapted for use with a feeble or artificial light than with daylight or magnesium, which appears to offer the most advantages as a standard. Still, it is open to modification and improvement, while there are methods possible by which the light itself may be curtailed before reaching the sensitometer without the intervention of screens.

It is impossible to say how *small* an exposure to magnesium, or even to gaslight, would suffice to impress a rapid gelatine plate, and

herein lies the weak point of the apparatus described. Some of Muybridge's earlier exposures on *wet collodion* plates were calculated, he informed me, to have been no longer than the *two-thousandth part of a second*—in the camera, be it observed. What, then, can we imagine would be the duration of *direct* daylight or magnesium that would just impress a rapid gelatine plate?

To give some idea of the difficulty of reducing the exposure to the necessary point, I have made the following calculations:—If a disc revolving at a very high speed were pierced at a distance of about three and one-fifth inches from its centre, with a *pinhole* one-one-hundredth of an inch in diameter, a plate exposed behind it for *one second* would receive the two-thousandth part of a second's exposure where the pinhole traversed it. That being the camera exposure required to impress a wet plate, I think I shall be well within the mark in curtailing the exposure to the ten-thousandth of a second for even an ordinary gelatine plate, and to give that with the revolving apparatus would require the pinhole to be removed to a distance of sixteen inches from the centre. Moreover, the disc would have to revolve at a very high speed indeed, for even at the rate of 600 revolutions a-minute, successive exposures might vary as much as ten per cent.

The same objection—at least, with light rich in active rays—applies to the ingenious and elaborate "time" sensitometer of Mr. J. W. Newall, described in the JOURNAL some months ago. The difficulty of accurately measuring and mechanically subdividing extremely short periods of time is what we then have to cope with, and we must, therefore, see if we cannot adopt other auxiliary measures.

It is of no use suggesting the employment of feebler artificial lights. I have already pointed out what I consider the importance of adopting as a standard a light similar in character to daylight, such as magnesium. With that source of illumination it is possible by reducing the area of the aperture through which it passes to the actinometer, and by increasing the distance at which it is used to very greatly reduce its power without altering its character, and, if necessary, we may use a "standard lamp" with a pinhole aperture and place it at any reasonable distance in order to gain the needful degree of attenuation. I must say, however, that in my own experiments I have not got uniformly satisfactory results in that manner.

I had intended touching on other points, but find it impossible within my present limits. However, I am not unhopful that on the lines I have indicated we may some day be able to compare accurately, and in a rational manner, the sensitiveness of gelatine, collodion, or any other plates, and to state in mathematical terms the value in "standard candles of both sun and moon." When that "good time" arrives, it will be interesting to know how many "sixty times" plates come up to their description.

W. B. BOLTON.

THE IMPROVEMENT OF FAULTY NEGATIVES.

IV.

In my previous articles, when dealing with this subject, I referred somewhat in detail to what I considered was the best method of removing large opaque markings from negatives. We have, however, frequently to contend with faults or opaque marks in negatives of small dimensions, yet still sufficiently pronounced to cause eyesores or troubles in the finished print. I am not now referring to such flaws as come within the scope of being removed by the simple means of spotting out in the print, but those annoying marks which just get beyond being so treated.

To make a transparency and fill up such flaws, and from the same pull off a new negative, would by most people doubtless be considered a most troublesome and roundabout way of setting to work for the removal of such faults, and doubtless this would be so. Recourse must be had to other means of overcoming same. Therefore, in such cases a different treatment is advisable. Should the negative in which such are found be varnished, then the first thing to do is to proceed to remove the same, an operation by no means difficult, and which is rapidly done by flowing over the surface of the negative some *absolute alcohol*. Methylated spirit is not nearly so good for this purpose. Absolute alcohol acts much quicker, and in a few minutes will have so softened the varnish as to permit of its being easily wiped off with a soft cloth or clean handkerchief, leaving the film beautifully clean; and should there have been any defects in the varnishing, such as grit

or dirt, they will be found to be removed. Any small opaque flaws, such as I have referred to, and which are now found incorporated in the film, can be taken out with a scalpel. I know it is not many workers who have courage enough to take up and use a scalpel on their negatives, but once any one knows the proper way of setting to work, such timidity soon vanishes. Of course, there are those who are so clumsy with any tool as to be quite outside this work; it is certainly a delicate operation, but still not so much so as to deter any one gifted with a little neat-handedness easily overcoming it.

Were any one to take up a common penknife, and with its aid try to peck away at such spots, it is just about certain they would do more harm than good. Between a fine scalpel and a penknife, however, there is a wide difference in the operation we are considering, for let it be borne in mind it is not like setting to work at one's writing desk, and with a penknife scrape out some ink blots, an operation which every schoolboy knows a trifle about. It is not a *scratching* out operation we have to do with at all, but what I may term a *cutting up* or *breaking up* of the flaw we are wishful of removing. Therefore, my advice to those who are sufficiently bold to try their prentice hand at such work is, first, look out for some film that has such a case apparent as a small spot or mark—say about an eighth or a sixteenth of an inch in size—and having removed the varnish, place the same on a good retouching desk. Now with a very finely pointed scalpel, and the aid of a strong pair of spectacles, let him proceed not to scrape or scratch out the flaw, but make *fine cuts* or incisions right into the film. This will break up, as it were, the flaw, and after a very few of such it is wonderful how they will appear to have vanished. Should there be any clear glass showing through the film just where one or two incisions of the knife has penetrated down to the bottom of the film, such are quite easily spotted out with a pencil or brush after the negative has again been varnished.

Just let those who attempt this work for the first time bear in mind that it is not a digging out of the flaw, but a cutting into the same of very fine, transparent lines or snags. A good pair of strong spectacles, as I have said, are very useful to magnify matters, far better than a single glass, because they permit of entire freedom of the hands and help towards steadiness. A healthy eye with a strong pair of spectacles will get a good magnification at about ten inches off the negative.

Another prolific source of faults found in nearly all classes of negatives are those showing minute pinholes or transparent specks. Who is there that has not lost his temper at times on looking through his negatives after development and finding quite a crop of these annoying little visitors turning up, marring, as they frequently do, an otherwise almost perfect result? We are told dust is the cause of these troubles. Somehow I fancy the blame does not always lie at the door of the users of the plates, for I can well remember when, having something to do with a dry plate manufactory, we could always tell the day beforehand when a batch would have a few of these faulty platea. However, be the cause what it may, it is the removal of them we have now to deal with. Prevention is better than cure certainly, but when it is too late, and the best has to be done with just what one has got, then a power of patience will come in handy. Just lately I met with a provoking case of this sort. A young beginner had got a nice negative, but it had quite a colony of these pinholes. He thought the best way to get rid of them was to peck away with a finely pointed pencil and so spot them out. At it he went, but he was not long in finding out that he had not an easy job, for he was piling on the lead outside the holes. Now I know this sort of thing is by no means uncommon with novices; they never imagine that exceedingly small touches on the face of a negative can better be done with a very finely pointed sable brush and a suitable spotting material than can be accomplished with a pencil, yet such is the case. The brush must be a really good one, however, and the medium so applied as just to give the desired opacity. When undertaking this work a beginner is sure to err in laying the colour on too dense. In most cases only a slight modicum is required. A little practice, however, will soon teach a patient worker how to spot out pinholes with a brush. It needs unlimited patience.

Another case which recently came under my notice was that where a negative was marred by a hole somewhat larger than could be classed under pinholes. The picture in question was a seascape, and my friend had been trying hard to spot it out until he quite gave it up. I at once saw the similarity of the shape of the flaw to that of a duck, so taking a finely pointed needle a few touches soon had the desired effect, and that picture has been admired for its duck over and over again, and sells well at the present moment. When such flaws can be utilised in the manner described, by all means take advantage of them.

Another very common means resorted to for improving certain

classes of negatives is blocking out, skies that are faulty being a very common example of this kind. In many landscape negatives the mere blocking out of a sky is by no means a matter of difficulty, for where there are not many projections beyond the sky line, it is quite easy to run round the outline with a brush and black varnish, or some other suitable medium; but in cases where, say, vessels' masts with their rigging, form out prominently into the sky, it is next to impossible to block out such satisfactorily. When such happens, it is better to remove the faults from the sky and then proceed to gain density by means of a transparency, and from that again a new negative. It is not only in landscape negatives and such-like where faulty skies have to be dealt with that blocking out is of service; very frequently in such as architectural, engineering, and the copying of black-and-white subjects. In this category also may be included the removal of faulty backgrounds and the blocking out of statuary. Such work requires a good steady hand, and close application to do it properly. As a rule, black varnish comes in very handy, especially for the broad parts of such work, but where very fine outlines have to be followed I prefer to use a mixture which I have found very useful, and which I make up myself as follows:—Into a little flat penny ink bottle place a small quantity of red ink, then break up a tablet of Indian ink and put the same into the bottle. Now add a little gum. When this is well mixed we have a mixture that will work well with either brush or pen. Perhaps, all considered, as good results can be obtained by working with a finely pointed sable brush, but I have also found for very minute outlining that a lithographic pen works very well. Of course, fine work of this kind requires to be done on a retouching desk, and it is as well to have a little front light on the negative as well as that transmitted through; this enables the worker to see better not to overlap the lines. When doing this work the use of a strong pair of spectacles will improve matters considerably. Blocking out is not really hard to overcome; it only needs patience and neat-handedness.

I now come to the consideration of such flaws as are caused by accidents or carelessness, such as scratches, cracks, &c., and perhaps there is hardly any more troublesome fault to remove from the face of a negative than that of a scratch, when such happens to be in such a position as to make its presence felt. The filling up of same is not unfrequently attended with opaque markings all along their line, and this to some will appear as bad as the scratches themselves. When such is the case, perhaps there is no better way of proceeding than to go ahead and get rid of the scratches with as little overlap as possible; this done, pull off a transparency, work in the new transparent defects, and finally pull off a negative. In this manner much may be done to remove a serious scratch from the face of a valuable picture.

Cracked negatives may also be treated in a similar way, and when a duplicate negative has been secured (provided the crack has not injured the film), an operator may proceed to strip the film from the glass and lay it down upon a new plate which has been prepared with a coating of collodion and gelatine, or, what is perhaps simpler still, an Eastman stripping skin may be brought into requisition. It is not every one, however, who is expert at stripping an ordinary gelatine negative. Those, however, who have never tried it should practice on some negative of no value. The operation is performed as follows:—The negative, if cracked, must first be attached to another sheet of glass of the same size. This can be done in several ways, by glue or binding round the edges. When firmly fixed and bound together, the face of the negative is coated with a good thick coating of enamel collodion. When set, this is washed under the tap till all greasiness has disappeared.

The negative is then placed into a very weak solution of hydrofluoric acid (of not greater strength than four drachms to ten ounces of water). This solution must be contained in a leaden or rubber tray. After a short time it will be observed that the edge or corners of the negative will begin to leave the glass. Now a clean, stout piece of white writing or other suitable paper must be laid flat, and the negative, removed face down from the hydrofluoric acid, is brought and laid upon the white paper, and the surfaces squeezed into contact slightly. The edges of the glass are then sized, and with one or two vigorous shakes—if all has gone well—it will be found that the film leaves its original glass support and attaches itself temporarily to the white paper support. A prepared sheet of glass having been provided beforehand to receive the film upon, by first rubbing the surface with French chalk, and then collodionising and giving a final coating of a thick solution of gelatine, is now taken and immersed in a dish of clean water until the surface becomes somewhat tacky; this is then laid flat on the table, and the surface flooded with quite a pool of water. The film and paper are then grasped, and by a dexterous movement are turned up and drawn on to the gelatine surface and squeezed into contact, the paper afterwards being removed and, if

desired, when dry, the whole can be stripped off the glass and the negative recovered in the shape of a film alone. Hydrofluoric acid is not the most comfortable agent to work with, and due care must be taken when using it. After several trials, however, but very few failures will result, and the operation reduced to one of certainty.

Some workers use Eastman films in this operation, but the clean white paper does first-rate to keep the film on until it is brought into contact with its final support.

Such are a few of the methods which in my hands I have, and do, from time to time, bring into play when dealing with negatives that require doctoring. In nearly every case there will be much that will occur to the mind of an operator that is almost impossible to record in a paper of this kind. In concluding these articles, I think I cannot do better than say, that before proceeding to any of the methods of doctoring study the case well; and having done so, and made up your mind what is best to be done, set about it with confidence, for without doubt much better work will result than would be the case when a worker approaches the thing timidly.

T. N. ARMSTRONG.

COLOURED PHOTOGRAPHS.

CONCLUSION.

In our last paper we concluded our *second painting*, and I think, with certain *rational* modifications, there is nothing laid down for the legitimate production of a water-colour portrait that cannot be applied, with equal advantage, to the painting of a similar portrait upon a photographic base. I see no very strong reason, therefore, if we treat both pictures virtually the same, why both should not possess sufficient merit to be classed as works of art. To my thinking, if there be any argument at all upon this point, it would be more likely to reflect unfavourably upon the *artist* than upon the *work* he produces. In other words, it is more likely that a man who *only* paints upon a photographic base may be somewhat less entitled to the distinction of being called an *artist* than that his works should possess so little merit as to be unworthy to be classed as a *work of art*. This would appear more evident if we were called upon to pronounce a verdict upon the merits of a work without knowing whether or not photography had lent a helping hand. We will now push along with our *third painting* and the general finishing of our work.

Having before us now a picture with a generally harmonious tone all over it, we will at once see there is a lack of vigour and force, which we must try to alter. This we can do by *taking out* the high lights and putting in the strong "darks," without which no picture possesses finish or solidity. It will, however, be well, before attacking these points, to generally look over our entire face, starting from the forehead and proceeding downwards, thoroughly *finishing* as we go along. In doing this the directions laid down for the second painting will carry us through, only in *fining* up the face we must place our work *between* the hatching already on or we may deepen the colour, and this would result in heaviness. It will be worth noting that if our shadow-tint above the eye should be too purple we must correct it with a greenish tint; if too green we should use *flesh colour* instead. If we wish to *lower* the blue of the iris use sepia and cobalt in judicious proportions. This applies equally to the *white* of the eye: We must paint the eyelashes with sepia, not trying to put in each hair, but, broadly, as if we were painting a shadow.

Assuming that we have given due attention to these points we come to the *high lights*, which we must *take out* before we go any further. A good method of doing this is as follows:—Take a clean brush, dip it in water; with this mark out accurately the form of the light to be taken out. This done, rub quickly (but in a horizontal direction) with a soft clean rag. This will have the desired effect; if more light be required it can be repeated. If the *outline* of this light should be too hard we must soften it by working upon the edges with the adjacent colours. Bear in mind, too, that in nature there is no such thing as outline, so we should try to make all our tints blend softly one into the other.

This done, we proceed to soften and round every part that seems to require it. Keep before us the fact, too, that *shadows* also indicate form, therefore we must paint them full in colour, exact in form, and warm in tone. If our shadows be too *purple* we must neutralise them with green, if the reverse, that is, too *green*, work upon them with purple, and if they are too blue hatch them with orange. A tint for the latter purpose may be made from Venetian red and yellow.

For all retiring points of our portrait grey must be largely used, as such we will find in nature. The corners of the mouth will require, no doubt, a few touches of shadow colour, and the edges of same softened by a delicate blue or grey. The ear is always semi-trans-

parent, and should be painted with a view to preserving this quality. The shadows of the ear should always be *warm* if not red.

If any of our work should appear coarse or wiry, we can soften this by applying plain water with a clean brush and wiping off *quickly* with a clean rag and then replacing as much of the colour as we may think necessary. This mostly refers to a more or less *fair* head, but judiciously thought over can be modified to suit all complexions. The light in the eye should be put in with the point of the brush charged with Chinese white. As water colours dry without a gloss, a little gum may be used in the strong shadows to give depth and transparency, but should be used sparingly and *never* until the picture is finished as regards the painting.

With this we will conclude, and I trust what I have laid down and we have figuratively done together will have appeared sufficiently clear to all who have been good enough to follow these papers. I have always had a strong opinion regarding coloured photographs, and know artists perfectly capable to paint from the life who turn out portraits on a photographic base with all the freedom and vigour of their so-called *genuine* portraits. Works by such artists as I have in my eye while I write are more deserving to be classed as works of art than under the contemptuous title of coloured photographs.

REDMOND BARRETT.

PARIS EXHIBITION, 1889.—PROCESS BLOCK MAKING.

ARTISAN'S REPORT TO THE MANSION HOUSE COMMITTEE.

EXHIBITION—Goupil & Co.—Commencing with the Exhibition. I may dismiss it in a few words, as there were not any firms, either English or foreign, exhibiting the process or method of producing process blocks; and only one French firm—that of Boussod, Valadon, et Cie., successors to Goupil et Cie.—that had an exhibit of specimens of process block work. These certainly were very fine specimens of photogravure. I might mention those that struck my attention; they were all produced from wash-drawings by the artist named: *An Oriental Scene*, by E. L. Weeks; *Horses and Foals*, by R. Goubie; *Two Children Asleep*, by L. Perrault; *The Sailor's Wife*, and *Pushing off the Boat*, by G. Haguette. There was but little in them to show the method of production; but they were most probably obtained by the ordinary grain-screen method in the camera. They were printed on fine thin paper and then mounted on cardboard. There were also other results produced by the half-tint process in colours of an artistic nature. This exhibit was in the Liberal Arts Gallery.

Illustrated London News and Artists' Drawings.—There were some very good specimens of wash-drawings, suitable for the half-tint process, in the *Illustrated London News* exhibit, by Forester & Woodall, the shadows not being too heavy and the high lights being toned down. This may be of some use to artists who wish to draw for the half-tint process. It may not be out of place to mention the conditions necessary to obtain the best results for line work, as frequently drawings are made not at all suitable. White cardboard should be used, and a black ink that dries a dead colour, not glossy. It is well to have a little gamboge or sepia in the ink. If the drawing has to be much reduced the lines should be thick and wide apart, that is, the work should not be too fine. These hints, if acted on, would prevent both the artist and the process being brought into disrepute.

Obtaining Information.—It is very difficult to obtain detailed information of the process as worked by different firms in Paris; for although there are no secrets in the methods used in the trade, the details on which so much depends, so as to obtain the best results, are kept to themselves by the various firms. On the whole, the methods used by firms in Paris and London are the same in principle and general application.

Information Obtained.—For much of the following information I am indebted to the firm of Messrs. Krakow & Michel, Rue de Fleurus, and to M. F. Perriot, Secretary of the Photogravure Society of Paris; and, for confirmatory knowledge, to the book published by the Labour Bureau, containing the answers to questions addressed to various trade societies.

Visiting Workshops.—Application was made to the following firms for information and permission to visit their workshops, with the result that a favourable reply was received from Messrs. Krakow; and an answer from Messrs. Boussod, Valadon, et Cie., that it was not their custom to give information, or to allow visits to their *ateliers*, although they answered a few of the questions addressed to them; also from Messrs. Dutheil, stating that it was impossible for me to visit their place. From the others no reply was received.

The firms written to were:—

Firms applied to.—1. Messrs. Krakow; 2. Boussod, Valadon, et Cie.; 3. Dutheil; 4. P. Dumont fils; 5. Garnier; 6. Lefman; 7. Minot; 8. L. Rolla; 9. Rose Victor; 10. Clicherie Générale; 11. Michelet.

Quality of Work—Materials Employed.—The work turned out by Parisian firms is certainly as good, and sometimes better, than by London ones; but the materials employed and the methods are, generally speaking, the same. No process depending on any new principle is employed; the improvement being more in the manipulation, depending on the individual workman and the time taken, which is a little longer than is usual in England.

Prices—Cost.—This is a difficult subject to report on, although it is a very important one, prices varying as they do in London, depending on the kind of work, the quality, and the trouble and time taken in obtaining a result. There are, I am informed, firms in Paris that take in any kind of work, cutting down the prices and obtaining inferior results. Still, as a criterion, it might be mentioned that work is frequently sent to Paris from England, but seldom or never to London from France, which shows that the prices are less, and the quality as good in Paris.

Wages—Mode of Payment.—Wages are paid on the Saturday, with the exception of the photographers, who are paid monthly. Photographers are paid 14*l.* 10*s.* per month by one firm. The amount varies in Paris from 10*l.* 10*s.* to 18*l.* 15*s.* per month. Printers are paid about the same as operators. Transferrers can earn from 2*l.* 10*s.* to 3*l.* 10*s.* per week, and the lithographic artists from 2*l.* to 3*l.* 10*s.* per week. Engravers receive from 2*l.* to 3*l.* 10*s.* weekly. There are about ten engravers in Paris who earn 3*l.* 18*s.* weekly. They are all paid in hard cash. In two firms the men, I understand, share in the profits of the employer, and the employers insure the lives of their *employés*. There are no fines in the trade. It is not the custom in France to give any notice on either side, and the engagement may be broken at a moment's notice.

Hours of Work.—The hours of work throughout the trade are ten; this is the usual time for most trades in Paris. In one house they commence at seven and leave off at six in the summer, and in winter they work from eight to seven. They have an hour, from twelve till one, for dinner. There is no Saturday half-holiday, and although Sunday is usually a rest day, in one firm they work on that day if necessary. They have about seven days' holiday per year. Overtime is worked and paid for at 2½*d.* extra per hour over the ordinary time rate. There is work all the year; but for about two months trade is somewhat slack.

Piecework.—There is no piecework; it has been tried by the employers, but has not proved a success. There are no sweaters or jobbers, but there is the usual division of work—photographers, etchers, mounters, &c.

Female and Juvenile Labour—Apprentices.—There is no female or very young juvenile labour. There are a few apprentices who are paid from 4*s.* to 12*s.* 6*d.* per week. They earn about 4*s.* 2*d.* per week for the first year, 10*s.* second year, and 12*s.* 6*d.* the third year, besides which they have a Christmas-box, and also encouragement money if they become useful. There is no premium paid, and the agreement is usually for three years, commencing generally at about fourteen; but it must be understood that apprenticeship as in England does not exist in France; there is only a mutual arrangement, but it cannot be legally enforced by either side, and can therefore be broken at any moment. Improvers are paid about 25*s.* per week. The head of one firm said that he did not think it paid to employ much juvenile labour; and this is no doubt correct if the best work is desired.

Power.—Steam power is largely used for driving the dynamos for lighting purposes, lithographic machines, etching boxes, and saws.

Manner of Life—Living—House Rent.—They have only two meals a day in Paris; one from twelve to one, and the other after half-past six. Their meals are principally obtained at the restaurant, or from the cookshop, very little cooking being done at home. In the early morning they have a cup of coffee or wine, and a very little to eat; and in the afternoon the same while they are working. There is no tea-meal or supper, as we have in England. As to cost of living and house rent, it is a somewhat difficult subject, varying as it does with the ideas of the individual; but while living is about the same as in England, house rent is higher and clothing dearer—living costs about 7*s.* per week, and rent is from 1*s.* to 4*s.* per week higher than in London for the same accommodation, workmen live principally in flats, there being very few small houses as in London. Their families are not so large as is frequently the case in England. Travelling is cheap by tram, bus, or boat.

Photography.—Steinhil's lenses are chiefly used in copying. Negatives are taken up to about 24 × 22. The wet collodion process is principally used as in England. Bitumen is largely used for printing

on zinc. In one firm, besides printing on zinc, the following well-known method is largely used:—Take an ordinary negative and print on photo-transfer paper, transfer to stone, touch up and make perfect, pull transfer, and transfer to zinc, and etch in. This has advantages if the original is imperfect; but printing direct on the zinc is better if the original is good, as in the transferrings one is liable to lose some of the work, as well as thicken the lines. In one firm an ordinary camera is not employed; the dark room is used instead, the lens being fixed on the wall, the copying board consisting of an iron framework carrying the board, and running backwards and forwards on rails. Inside the room, the ordinary dark slide, carriers, and bellows are dispensed with, the focussing screen and the plates being inserted in a framework with moveable sides, so as to take any size glasses. This plan has advantages over the ordinary way. The negatives were taken on plate glass, nearly a quarter of an inch thick, were of a black colour and very good quality. In the same firm, for half-tint work, they printed on copper, affirming that, although it was more expensive than zinc, better results were produced. The Brush dynamo is principally used. In one firm the Dubosq electric lamps were used, but they are no better than the ordinary type employed in England.

Etching.—Two large plates are considered a fair day's work, and but little small work seems to be done. The boxes are driven by steam power; the method is very simple. A long iron rod is kept revolving by a strap from a pulley; on this, at intervals, are fixed eccentric pieces. These alternately push up and let down the boxes under which they are placed, imparting to them a rocking motion, which is more regular and less liable to stoppage than by using hand power. The boxes are stopped by a lever, which takes them off the rod. Guttapercha is used for lining the boxes; it is said to withstand the acid better than pitch, one box having been in use for eight years only having had a few repairs. The ordinary method of etching with nitric acid is used.

Mounting.—Mounting is done on mahogany as in England. A circular saw is used for cutting the wood, but a fret saw for the zinc. The fret saw seems to have advantages over the circular saw, as it is able to cut round corners more easily. These are driven by steam power. A hand drill is used for making the holes in the metal previous to mounting, and a plane, running in a groove, is used for planing the sides of the zinc.

Work in Paris for Englishmen—Trade Society.—I was informed that Englishmen who knew the process well, and were good workmen, could obtain employment in Paris; but it would be well to apply to the *Chambre Syndicale of Photgraveurs*, by whom a registry and hiring book is kept. The Secretary is M. F. Perriot, and the address is Bourse du Travail, 35, Jean Jacques Rousseau (Bureau 11).

American.—Although there is no American exhibit in the Exhibition, I should like to draw attention to the fine specimens of the half-tint process in American periodicals. I need only mention *Paper and Press*, *The American Art Printer*, *The Inland Printer*, *The American Annual of Photography*, and *Annual of Anthony's Photographic Bulletin*. These all contain numerous specimens of work by American engravers and printers.

The fine qualities of these specimens may be largely attributed to the good rolled paper, black ink, and careful printing, to all of which it will be necessary for English printers to pay more attention, so as to get equally good results. As specimens of English process work, might be mentioned the *Guide to the Paris Exhibition*, in English, printed by W. Clowes & Sons. This, although good, lacks the cleanliness and brilliancy of the American productions. At the same time, I understand the price for a process block is greater in America than in England; but as cheap and nasty usually go together, it would be better to pay more and have finer results.

Map work is largely done by one firm, zinc blocks for chromo work and music work by another. For music work the usual method is practised; lines are cut in a lead alloy plate, the notes, &c., being punched in by a special punch. A transfer is taken from the plate and transferred to zinc, which is etched in the usual way.

As the firms visited were, I understand, the best in Paris, there was not much opportunity of obtaining information in regard to the cheaper kind of work done.

On the whole, the conditions of work and the workmen are pretty nearly the same in London and Paris. Although the wages are slightly higher, the hours are longer, being at least sixty per week in Paris to forty-nine in London, and the entire expense of living would be found slightly higher in Paris than in London. It seems to me that more attention should be paid here to the artistic side, and to the printing of the finished block in the letter-press machine, and we should soon equal our French neighbours and American cousins.

H. G. WALSH.

NOTES UPON A PROPOSED PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.*

Roman Warwickshire.—As Julius Caesar (B.C. 55) did not advance north of the Thames, his famous "Commentaries" tell us nothing directly of Central England. But a later Roman leader, Ostorius Scapula, established a line of forts along the Severn in A.D. 50; and he and his successors during the next four centuries made those famous "Roman roads" which were indispensable to the conquest of the country. Three famous Roman roads run through Warwickshire. The most important is the Watling-street, which extended from Richborough, in Kent, to Chester. It enters Warwickshire near Rugby, and from thence to Atherstone it separates the county from Leicestershire. At High Cross, about half-way between the two towns, the Watling-street is crossed by another Roman road, called "The Fosse-Way," which extends thence to Stretton-under-Fosse, in the south-west of Warwickshire, a distance of forty miles. It runs in a nearly straight line, up hill and down dale, with deep cuttings and many picturesque views; a true "old-world" road, and but little frequented now. Who will walk its length with a camera and resuscitate the Roman? I knew this "old Fosse Road" well when I lived in Leicester, and antiquaries have traced it all the way from Cornwall to Lincoln.

But the Roman road best known to dwellers in Birmingham is the Icknield-street (or Ryknield-street, as it is sometimes called, to distinguish it from another road of the same name). It enters the county in the south at Bidford, and runs nearly due north through Birmingham (where one long street still bears the name), to meet the Watling-street at Wall (the Roman station of *Etoctetum*), near Lichfield. For three miles in Sutton Park, on the north of Birmingham, the line of this fine old road is quite distinct as to direction, width, and level, although it is, of course, grass-covered. Beyond Warwickshire this Ryknield-street extended to Gloucester and St. David's in the one direction, and to the Humber, and thence to the Tyne, in the other.

Besides the Roman roads, practically the only certain traces left of the Romans in Warwickshire are the Roman rectangular camps, or fortified stations, at Manduessedum (close to Mancetter), and at Oldbury, in the same district; with another at Chesterton, on the Fosse-Way, six miles south-east of Warwick. These camps are well-defined, grassy mounds or "walls" of earth, enclosing a large central area. They will not be easy to photograph, and the best time for securing their outlines will probably be either early or late in the day, when shadows will accentuate their outlines.

Other important Roman stations are believed to have existed at *Præsidium* (Warwick), *Tripointium* (Cave's Inn, near Rugby), *Alauna* (Alcester), *Bennones*, or *Vennones* (High Cross or Cloudeley Bush).

Roman remains, coins, pottery, &c., have also been dug up at Brinklow, Monk's Kirby, and Wiltot. These latter relics appear to have been dispersed, and are probably now lost to us. They could all have been preserved and collected for purposes of study by their reproduction by photography. In the Warwick Museum there is a Roman tomb, or sarcophagus, found near Alcester.

Saxon Warwickshire.—The Romans were little more than visitors to Warwickshire, and they probably seldom, if ever, penetrated the recesses of Arden. After their departure in 449 A.D., they were succeeded by the Saxons, who "came to stay." And yet the Saxons cannot be said, in the ordinary sense of the term, to have "conquered" the Midlands. The tribe of Angles (from North Germany), who landed on our eastern coasts, very slowly advanced inland, and only by slow degrees gained power over, and amalgamated with—rather than subdued—the Celtic inhabitants of Arden.

Warwickshire formed a part of the Saxon kingdom of Mercia, which flourished under Cridda, Ethelbald, and Offa, from the sixth to the ninth centuries; after which the eight Saxon sub-kingdoms (the Heptarchy) united to form the Anglo-Saxon kingdom (827–1066).

Many of the tumuli or mounds of earth (sometimes so large as to be actually small hills) which stud the surface of Warwickshire, contain the remains of Saxon chiefs; but without actual exploration we cannot distinguish the Saxon from the Celtic tumuli. At Walton, near Wellesbourne a Saxon grave, which was opened in 1774, contained "three skulls lying in a row, with two Saxon jewels set in gold, one with an opal and two rubies, and the other adorned on both sides with a cross, between two rude human figures, with a sword or lance at the outer hand of each." Iron swords and the iron bosses of shields are also commonly found in Saxon interments; while stone implements, &c., accompany the bones of the Celts.

It is probable that during the next few years many of the as yet undisturbed tumuli will be explored; and it is earnestly to be hoped that photographs will be taken, recording each stage of the operations, and especially as showing the positions of the interred skeletons, whether lying on the side or back, and with legs drawn up or extended, as each of these points appears to have characterised different times and different nations.

Of undoubted Saxon remains we can only point to two places in Warwickshire. The first of these is at Tamworth Castle, just within the north-eastern boundary of the county, where the "herring-bone work" in

* Concluded from page 830.

the base of the lower wall is very characteristic. The second example is at Wootton-Wawen, where the lower half of the church tower is certainly of Saxon masonry. In each of these cases we want photographs taken from a moderate distance, showing the entire building, &c., and also several near views in which each stone would be distinctly represented. The best evidence of the complete colonisation of Warwickshire by the Saxons consists in the numerous Saxon place-names which still remain. The names of the rivers and hills—as Arden, Avon, Rea, &c.—are certainly Celtic, but most of the towns and villages have the truly Saxon affixes of “ham,” “ton,” “ley,” “thorpe,” &c. It is now pretty well acknowledged that the name of our new city—Birmingham—represents the dwelling-place (*ham*) of the tribe or descendants (*ing*) of Beorm; the said Beorm or Biorn being a Saxon chieftain.

The Danes, who ravaged the east and south of England so unmercifully in the ninth and tenth centuries, are thought not to have advanced beyond Rugby, the termination by being distinctively Danish. The gigantic ruddy animal which (carved out in the turf) ornaments the “Vale of Red Horse,” near Kineton, in the south-east of the county, may be either of Saxon or of Celtic age, although there is a legend which assigns it to Neville, Earl of Warwick, in the fifteenth century. Neville may perhaps have “scoured” it.

In the same direction, and just on the county boundary, are the famous Rollright Stones, some of which are seven feet in height. They resemble somewhat the famous stone circles (Druidical) of Stonehenge and Avebury, and are more probably of Celtic rather than of Saxon times.

The famous legend of Lady Godiva belongs to the very close of the Saxon period. Godiva (properly Godgiva) was the wife of Leofric, a powerful Saxon noble who died in 1057. He and his wife richly endowed a monastery and church at Coventry; and Dugdale records that in a stained-glass window in Trinity Church, Coventry, the stout earl and his fair wife are depicted, the former bearing in his hand a scroll with the inscription:—

“I, Leofric, for the love of thee
Doe make Coventre Tol-free.”

As in Leofric's time the population of Coventry was only 350, while the houses were but one storey high, with a door and no windows, the legend of “Peeping Tom” is in the highest degree incredible. As a fact, the tale probably originated during the latter part of the seventeenth century. Possibly some future historian will find in “Peeping Tom” the prototype of the man who carries a detective camera.

Many Saxon laws and customs have survived down to our own times; and to the Saxon rulers, in fact, we owe the very outlining of our county, as indicated by the word “shire.” They divided the “shire” into large divisions called “Hundreds,” and in Warwickshire we have:—

- I.—Hundred of Hemlingford, including Birmingham, Solihull, Atherstone, Tamworth, &c.
- II.—Hundred of Barlichway, including Alcester, Stratford, Henley-in-Arden, &c.
- III.—Hundred of Kington (or Kineton), including Warwick and the south-east of the county.
- IV.—Hundred of Knightlow, including Kenilworth, Rugby, Southam, &c.
- V.—Coventry, with a district around it, known as the “County of Coventry.”

It is possible that these “Hundreds” may form convenient sub-divisions for the purposes of our photographic survey, in which case the Birmingham Photographic Society would naturally commence with the Hundred of Hemlingford, whose area is about one-fourth (say 220 square miles) of that of the entire county. It is somewhat unfortunate that our city of Birmingham should be situated on the extreme north-west margin of the county; but the “county,” as a unit, is so much superior to any other that it must, perforce, be adopted.

Medieval Warwickshire.—With the conquest of England by the Normans in 1066, the written history of Warwickshire may practically be said to commence. In the Domesday Book we have a survey of the county, which includes the names of all the possessors of land, with the area and value of their possessions. With the Normans, too, we get the first important building operations—they erected many churches and castles. The monuments of the mediæval age (which extended from the eighth to the fifteenth centuries) include the most striking buildings in Warwickshire. The great castles of Warwick and of Kenilworth were, until the invention of gunpowder, practically impregnable fortresses, while Maxtoke Castle, if smaller, is even more interesting, for its “moat and outer walls and its old iron-bound gate and gatehouse are scarcely changed during 600 years.” Astley Castle, near Nuneaton, dates from the thirteenth century, when a castle was a fortified house with a moat. Tamworth Castle we have already mentioned.

The close of the mediæval period saw also the destruction of the monasteries and other religious houses by Henry VIII. (1539); but Maxtoke Priory, Polesworth Nunnery (near Tamworth), Merevale Abbey (near Atherstone), the Whitefriars Monastery at Coventry, &c., still remain (in a more or less delightfully ruinous and picturesque condition) to testify to the religious zeal of our ancestors.

And the old churches, how delightful they are! Shall it not be our

See that capital book, *The Scouring of the White Horse*, by Tom Hughes, in which describes similar work in Berkshire.

pleasure to record their every detail and architectural feature, so that when the hand of the “restorer” is laid upon them there shall be evidence retained of their original structure and condition? To take but two cases. “As an example of a preceptory and church of the twelfth century, of which neither restoration nor neglect have changed any important feature, Temple Balsall is unrivalled in Warwickshire, and not surpassed in any part of England.” Let the Beauchamp Chapel (1465) in St. Mary's Church, Warwick, be our second example. It is, without doubt, as a sepulchral chamber “one of the most famous in the kingdom, containing among others the tomb of Richard Beauchamp, Earl of Warwick, the cost of which alone exceeded 40,000*l.* of our money.”

Of moated houses and picturesque old mansions Warwickshire has many. Compton Wynyates (1510) is described by Timmins as “a marvellous and harmonious combination of the best and most artistic work in brick, stone, and wood. Its variegated colours of bricks, its richly-moulded brick chimneys, its exquisitely carved gables and beams and wainscoting, its bold and vigorous and delicate stone carving, its noble rooms and great hall with minstrels' gallery, its ninety rooms, with a secret chapel in the roof, its long lines of dormitories for soldiers, its venerable, moss-covered, and picturesque quadrangle, combine a series of charming views which are unequalled in Warwickshire and unsurpassed elsewhere.”

Of slightly earlier date is the old fortified manor house of Baddesley Clinton—“charmingly picturesque, for it has a fine ancient moat surrounding its grey walls, and quaint gables and chimneys, and its pretty garden parterres surrounded on three sides by the rooms of the house.”

Guy's Cliffe, two miles north of Warwick, is pleasingly described in Camden's *Britannia*, written in 1586:—“Hard by the River Avon standeth Guy Cliffe, the very seat itself of pleasantness. There have ye a shady little wood, cleere and cristall springs, mossy bottomes and caves, meadows alwaies fresh and green, the river rumbling here and there among the stones with his streame making a milde noise and gentle whispering; and, besides all this, solitary and still quietnesse, things most grateful to the Muses. Heere, as the report goes, that valiant knight and noble worthy, Sir Guy of Warwicke—so much celebrated after he had born the brunt of sundry troubles and atchieved many painful exploits—built a chapel, led an eremit's life, and in the end was buried. Howbeit, wisemen doe think that the place took that name of later time by far from Guy Beauchamp, Earle of Warwicke; and certain it is, that Richard Beauchamp, Earle of Warwicke, built St. Margaret's Chapell heere, and erected a mighty and giant-like Statue of Stone, resembling the said Guy.”

Warwickshire in Later Times.—During the sixteenth century many most interesting buildings were erected in Warwickshire, including Pooley Hall, near Tamworth; Weston Park, Shipston-on-Stour; Wormleighton; the Leicester Hospital, at Warwick, &c. Aston Hall (1618) is a fine Elizabethan mansion standing in a northern suburb of Birmingham, and now the property of the Corporation.

At the opening of the seventeenth century we find a Warwickshire man—Robert Catesby—acting as the proposer of the “Gunpowder Plot;” and quite lately it has been shown that the famous—or infamous—Guy Fawkes himself hailed from our county. Catesby was born at Bushwood Hall, Lapworth, and it is believed that the details of the plot were arranged there and at Norbrook, Clopton (near Stratford), and Coughton (the seat of the old Roman Catholic family of the Throckmortons.) The Princess Elizabeth was then residing at Combe Abbey, near Coventry; and the local conspirators arranged a hunting match at Dunsmore, near Dunchurch, for the 5th of November, intending, as soon as they heard of the success of the plot, to carry off the Princess and proclaim her Queen of England. When the news of the arrest of Guido Fawkes arrived, the conspirators fled into Staffordshire, where they were pursued and captured at Holbeach, Catesby being shot dead in the attack.

The Civil War in Warwickshire.—The first battle between the Royal and the Parliamentary forces was fought in 1642, on the plain below Edgehill, near Kineton, in the south-east of Warwickshire. The scene remains almost unchanged; and with the assistance of a few lantern slides (especially if our friend Mr. Jaques would supply moveable bodies of troops for the occasion) the eventful struggle of that day could be pictorially reproduced in a most graphic manner. This would be a novel and interesting way of teaching history.

Warwickshire Worthies.—To illustrate the local incidents connected with the lives of famous men and women who have been born in Warwickshire will be a pleasant task for the camera carrier. The plain stone farmhouse at Griff, near Nuneaton, acquires a halo when we know it as the birthplace of “George Eliot;” and all the country round is described in her various novels as accurately as in a guide-book. We shall associate the great antiquary—Dugdale, Garter King-at-Arms—with his home at Coleshill; David Cox with the Birmingham suburb of Harborne; Bishop Vesey with Sutton Coldfield; Dr. Priestley (the discoverer of oxygen) with the Birmingham suburb of Sparkbrook; Dr. Arnold and Rugby School; Matthew Boulton (who sold “what all the world desired—power”) with Birmingham; Michael Drayton (the poet) with Hartshill; and many another famous name shall add interest to our work. But, far above all, we possess in Stratford-on-Avon and the neighbouring country such an illustration of the life and work of the immortal Shakespeare, that this alone would be sufficient to render Warwickshire one of the

most interesting spots of the whole world in the eyes of all civilised nations! When the first Shakespeare jubilee was held at Stratford in 1768, the most popular song was that written by Garrick, in which the main feature is the connexion of the bard with the county:—

"Ye Warwickshire lads, and ye lasses,
See what at our jubilee passes:
Come revel away, rejoice, and be glad,
For the lad of all lads was a Warwickshire lad,
Warwickshire lad,
All be glad,
For the lad of all lads was a Warwickshire lad."

The Warwickshire of To-day.—And, lastly, we come to our own times. It is clearly our duty to secure, so far as in us lies, a faithful representation of the state of things as it is to-day. For every year we are "making history," and such a record will be just as much prized by posterity as we should ourselves prize it did it exist for the past. Just think what would be the value of good photographs of Bacon and of Shakespeare; or of Queen Elizabeth and her minister Cecil! Looking forward into the centuries, we can discern a time when no less value will be assigned to Mrs. Cameron's grand photographs of such men as Herschel and Tennyson with those by other workers of our good Queen Victoria and her "men of mind"—Salisbury and Gladstone!

We must accumulate portraits, then, of all our local worthies. And to them we must add street scenes—secured with the hand camera—from all our towns; delineations of the avocations of the people must also be obtained—from the country labourer in his smock-frock (a garment now rapidly disappearing) to the skilled artisan of the city seated before his lathe. Nothing that illustrates contemporary life must be omitted—the policeman, the soldier, and the volunteer must adorn our albums; and we must go "slumming" to depict the shady side of life.

Most congenial will be the task of recording the cottage and village scenery of Warwickshire. I have travelled round the world, I have spent many holidays in various parts of the British Isles, and I can assert, without fear of contradiction, that for characteristic pictures of rural and home life our county is unequalled. Take the string of Shakespearian villages along the Avon, for example:—

"Piping Peabworth, dancing Marston,
Haunted Hillborough, hungry Grafton,
Dadging Exhall, Papist Wixford,
Beggary Broom, and drunken Belford."

Let any one who loves English scenery drive (with his camera under the box-seat) from Warwick, through Charleotte (the home of the Lucy), to Stratford; and thence on to Evesham and Tewkesbury, calling at the villages named in the above quatrain (said to have been penned by Shakespeare) en route. Let him not hurry—take a fine week in, say, June—and I will answer for it that he will ever afterwards mark that excursion with the whitest of white stones.

In writing this brief account of our county, I must acknowledge my indebtedness to Mr. Sam. Timmins's recently published *History of Warwickshire*; but I have also studied most of the original authorities from Dugdale to Halliwell. Our noble Free Reference Library contains practically everything that has been published on Warwickshire; and some useful county books are also to be found in the Old Library.

If we are to "survey" Warwickshire in earnest, we must become students as well as photographers (and to my mind this will be one great good resulting from the task); we shall have to think of something else besides the beautiful and the picturesque, and we must remember that its associations may dignify the meanest dwelling, and render of world-wide interest the most prosaic surroundings.

Scientific Studies for Warwickshire Photographers.—Archæology—the study of the past, and ethnology—the study of the inhabitants of the district at the present day—we have already touched upon. But there is much work also to be done in geology, botany, and zoology.

The Geology of Warwickshire.—The coloured maps issued by the Geological Survey show the different strata of which the surface of the county is composed, and in a book which I wrote in 1881* a general description of the rocks of the county will be found.

Every landscape depends for its main outlines upon the rocks which lie beneath the soil, and for those who can "read the rocks," the study of the scenery of any district has a double pleasure. The oldest rocks of Warwickshire are the Cambrian quartzites and shales which lie between Atherstone and Nuneaton. These had been wrongly assigned to the Carboniferous period by the Geological Survey, and the discovery of their true age was made by Professor Lapworth and myself in 1882. The quartzites (altered sandstones) are insignificantly exposed in a series of immense quarries, and they are traversed by great masses of dark igneous rocks. The shales are well seen in the Stockingford railway cutting.

In the Warwickshire coal field, photographs of the surface works, collieries, and colliers might be secured; while descending beneath the surface, the flash light would enable us to secure interesting records of the mines and miners.

Of the Triassic strata which succeed, there is a fine section of the red sandstone, sixty feet in vertical height, at Hockley Cemetery, in Birming-

ham. Elsewhere the Triassic rocks are but seldom exposed, and we must be content with noting the level plains and rolling hills produced by their marls and sandstone.

The Liassic strata—limestones and clays—which rest upon the Trias, are quarried at Wilmore, Binton, &c., in South Warwickshire. The fossils contained in these and in other local rocks, of which there is a grand series in the Warwick Museum and in the museum of the Mason College, Birmingham, will form interesting subjects for our cameras.

Lastly, we have the drift, including those confused beds of clay and sand often containing great blocks of rock (erratics) which have been conveyed from Wales or from Scotland by the agency of ice during the glacial epoch. The immense boulder which lies in Cannon Hill Park (Birmingham) is a fine example of such a travelled block; but there are hundreds of others, and they are continually being destroyed—the farmers blow them up with dynamite. So, too, with the sections, the quarries, railway cuttings, &c., where the solid rocks are finely exposed. They change from day to day, until at last they are grassed over and lost. Let it be our task, by the aid of photography, to record their features for ever for the students of geology.

The Botany of Warwickshire.—The flora of our county has been carefully studied and described by Messrs. William Mathews, M.A., J. E. Bagnall, A.L.S., W. B. Grove, B.A., and other specialists. Artists have long visited our parks—Packington Park especially—to portray the grand old trees which adorn them, remnants of the old forest of Arden. Photography can admirably record every twig and leaf. It is certain that good photographs of plants, especially if taken while growing in their native haunts, would help to vivify the dry leaves of herbaria, and they would be much valued by those who study and teach botany. I have seen some exquisite work in this direction done by one of our members, Mr. Charles Pomphrey. Let me advise those who make this branch a speciality, to photograph trees either early or late in the day, when the nearly horizontal rays illuminate their trunks. Let photographs of the same tree be taken at different seasons of the year; then shall you be able to prepare a series of "dissolving views," in which the tree shall be shown to bud and blossom, be covered with leaves, and anon be bare, yet beautiful with frost-rime.

Zoology of Warwickshire.—In the minute life which occupies our ponds and ditches there is a never ending field of work for the photographer who combines the camera with the microscope. Some of us know, too, that it is better fun to hunt with the camera than with the gun; and we hope to be able to photograph the local birds, &c., in their native haunts, and so to secure pictures which shall surpass the best efforts of the taxidermist.

METHODS OF CONDUCTING THE PHOTOGRAPHIC SURVEY OF A DISTRICT.

There are several ways in which the photographic survey of any district may be carried out.

I.—First we have what may be called the "no method." Each member of the Society or body by which the survey is to be carried out wanders at will over the district, photographing whatever pleases his eye, and sending in his negatives or prints to the Managing Committee. It is not necessary to point out the demerits of such a scheme.

II.—If there is any good, modern, and tolerably cheap county history in existence, it might well furnish the groundwork for a general photo-survey. Lists of all the places and objects named in its pages should be drawn up, and grouped according to locality; each division being then allotted to those workers who have volunteered their services. For Warwickshire the recent publication of an admirable County History, by Mr. Sam. Timmins, offers a capital opportunity, the more especially as the book itself contains no illustrations. Any member who wishes to form a very valuable and interesting volume can do so by pulling Mr. Timmins's book to pieces (which is just what its reviewers have not done), interleaving it with a series of illustrations such as I have suggested, and then having it rebound.

III.—But for an exhaustive photo-survey of Warwickshire, or of any other district, I believe the plan must be based upon a large-scale and accurate map; and we must go to nature herself for our illustrations. Fortunately we are now provided with a map or maps (the work of the Government Ordnance Survey) which are in every respect admirable.

(a) *The Old One-inch Ordnance Map.*—Warwickshire was mapped on the scale of one inch to one mile as long ago as 1830. This map is sold in "quarter sheets" at one shilling each, each quarter sheet including about 160 square miles. The entire county on this scale makes a map 59 by 42 inches, which is sold in sheets for 17s. 6d.

(b) *The New One-inch Ordnance Map.*—The map described in the last paragraph is now, in some respects, out of date. But a new one-inch map is being prepared (by reduction from the six-inch map) which will be a great improvement. It will be similar in size and price to the old one-inch map. We can hardly expect to have this map for Warwickshire for a period of several years.

(c) *The Six-inch Ordnance Map.*—This is the ideal map for the work of a photo-survey. Its large scale (six inches to every mile) allows every field, and even every tree, to be depicted. The orientation of buildings is clearly shown, so that the photographer can see beforehand when the light will fall suitably upon any building, ruin, &c., that he may have to travel a long distance to photograph. The issue of the Warwickshire map on this scale is very nearly complete. The county is contained in 200 quarter sheets, each measuring 18 by 12 inches, and including six

* *Geology of the Counties of England, and of North and South Wales.* Kelly & Co. Ss. (Now out of print.)

square miles. They are sold at one shilling each, and 195 have been published.

(d) *The Parish Maps* are on the still larger scale of twenty-five inches to a mile. Four of these parish maps contain an area equal to one quarter sheet of the six-inch map. Each parish map measures 38 by 25½ inches, and contains an area of a little more than 1½ square miles. These also are all but complete for Warwickshire; and in some cases, as in Stratford, the ruins of Kenilworth, &c., they will be very useful to the photo-surveyor.

(e) Lastly, there are the town plans, on a scale of 125 inches to a mile.

PLAN NOW PROPOSED FOR THE PHOTO-SURVEY OF WARWICKSHIRE.

1. A Committee must be appointed, by whom the details of the plan can be formulated.

2. The maps of the county on the six-inch scale must be purchased. For each sheet of the map there must also be a light cardboard box bearing the same number as the map. In this box, mounted prints of all the photographs taken from objects contained in that sheet of the map should be kept.

A similarly numbered set of negative boxes would be needed to contain the negatives belonging to each sheet of the map.

3. All photographers who would be willing to place their services at the disposal of the Society should send their names (in pairs, if preferred) to the Committee.

4. The Committee would decide on a certain patch of country to be surveyed, say that included on twelve sheets of the six-inch map, if twenty-four names were received. They would then allot the maps, by ballot or otherwise, among the workers, giving one map to each pair.

5. Let us suppose that two friends, A and B, are allotted a certain area, say that contained in one quarter sheet of the six-inch map, including an area of six square miles. They carefully study the map and draw up lists of the promising points. They read up the history of any churches, ruins, or other monuments of the past included within it. Then they visit it for the first time, *without their cameras*. They walk across and across the district, calling perhaps at the inns, the farmhouse, or the rectory, gaining information, and jotting down places and times when the light will be favourable. On their next visit they are accompanied by their cameras, and the negatives necessary to illustrate the area—perhaps only two or three, perhaps ten or twenty—are soon secured; or a second and third visit are paid if necessary. Prints are then taken and lantern slides made, and the results are handed over to the Committee.

6. If a sufficient number of subscribers could be obtained, it would be very desirable to publish, perhaps monthly or quarterly, a selection of the most interesting photographs obtained, accompanied by descriptive letterpress. There must be many people in the county who would prize such a local record.

7. The principal books and works of reference upon the county should be added to the library of the Society, and lists of the large collections of books, &c., on the same subjects contained in the local libraries should be posted on the walls of the Club rooms.

8. One night in each week might be considered a "rendezvous night," on which all who were interested in the work of the survey should meet at the Club rooms; and on, say, one evening in each session of the Society there might be a more public display of the results which were being obtained. The year's work in this direction would naturally form an important feature of the Society's annual exhibition.

Society Excursions Utilised.—Everybody knows the routine of an ordinary excursion of a photographic society. Some well-known spot is selected, the further away the better, as North Wales, Dove Dale, Haddon Hall, &c. If the day is fine twenty or thirty members attend, and they go round the place in a crowd, occupying themselves to a large extent in getting in, and out of, one another's way.

I would suggest that the excursions be made local, and that a routine of work be drawn up beforehand, in which each detachment of three or four members should be assigned some particular task to accomplish. Thus, in a half-day excursion to Warwick suppose twenty camera carriers present themselves; let this number be divided into five sets of four members each, the tasks being as follows:—(1) The Castle and grounds; (2) St. Mary's Church, including the Beauchamp Chapel; (3) the Leicester Hospital; (4) the town of Warwick generally, its two gates and old buildings; (5) Guy's Cliff. Given a fine June afternoon, and the work of the survey for that town might be accomplished very rapidly on this plan. But it supposes that a full programme, showing the work of each section of the party, be drawn up beforehand and distributed.

Utilisation of Work already done.—There are probably in existence some hundreds, or even thousands, of photographic negatives which would be of service in the history of Warwickshire. It must be part of our task to draw up a list of such negatives, showing their subjects, their owners, &c. Some of them may, perhaps, be acquired by gift, loan, or purchase. A separate record-book should be kept for those negatives which are already in existence; and a circular asking for information on this subject might be addressed to the professional photographers of the county.

Documents, &c., copied by Photography.—We must photograph not only places but things. Old documents, seals, plans, maps, various objects of antiquity, rare fossils, &c. All these will provide food for the

camera, and will add interesting pictures to our stock. One advantage of photography in this direction is that it enables us to *bring together*, for purposes of comparison, a series of objects which may be scattered in many collections. The facsimiles of documents, &c., obtained by photographic processes are far more valuable than copies by hand can be, since they must be literal and unbiassed; errors in copying are avoided, and the evidence of the photograph is practically as good (sometimes, indeed, it is better, because clearer), than that of the original.

Size of Photographs to be taken.—I fear it will be impossible to bind ourselves down to any definite size of negative. Perhaps it would be best to make the whole-plate size (8½ × 6½) our standard. By the recent substitution of celluloid film for glass plates, the weight of the photographer's equipment has been greatly diminished—that a whole-plate camera with film weighs no more than a half-plate camera with glass plates.

By the use of cases or boxes to hold separately mounted prints, the difficulty of a variety of sizes is largely avoided. If albums are made up, they could be of such a size as to hold one whole-plate print, or two half-plates, on each page.

For hand-camera work the usual size is the quarter-plate (4½ × 3½), and for pictures of this size separate albums might be provided, or they might be mounted four on a page of the larger albums. It must be remembered, however, that it is easy to enlarge or reduce negatives, so that they could all be brought to one uniform size if that were thought desirable. Or it is even easier to enlarge or reduce the prints as they are made from the negatives, if we use bromide paper, &c., for printing upon.

How other Societies (Literary, Artistic, and Scientific) can Aid in the Work of the County Photographic Survey.—I trust that it may be assumed, that the three photographic societies already in existence in Warwickshire (namely, the Birmingham Photographic Society—Hon. Secs., Mr. J. H. Pickard, 361, Moseley-road, Birmingham, and Mr. A. J. Leeson, 20, Cannon-street, Birmingham; Leamington Amateur Photographic Society—Hon. Sec., Mr. F. M. Gowan, 20, Beauchamp-square, Leamington; Coventry and Midland Photographic Society—Hon. Sec., Mr. F. W. Dew, The City Studio, Coventry) will do all they can for the work of a photographic survey; but very valuable assistance can be rendered by several other societies within the county whose aim is the furtherance of Literature, Science, and Art.

How Antiquarians, Scientists, &c., can Aid in the Work of a County Photographic Survey.—Now, although we photographers may know *how* to photograph, we do not always know *what* to photograph. We want the historian, and the antiquary, the literary man, the artist, and the scientist to aid us in this. We want these students of the past and the present to draw up lists of places and objects in each square of our map which they consider ought to be recorded; and we want them to tell us all about them, so that the pictures we secure may be of interest to us as well as to them.

Assistance from Landowners, Residents, &c.—The nature of our work ought to secure aid and assistance from occupiers in all parts of the county. Armed with an introduction, stating the object and plan of this survey, the photographer may hope to be afforded facilities for his work which he would otherwise scarcely venture to ask for. Those who occupy historically interesting or beautifully situated places, will certainly be willing to aid in such a task, which may really be called national; while to the guardians of our churches—the clergy—our scheme should appeal with special interest.

Required Funds to be Obtained by Subscriptions and Grants.—In the work here proposed it is thought that all the workers will be willing to help, not only by paying their own travelling expenses, purchase of dry plates on which to make negatives, use of apparatus, &c., but also by subscribing to raise the funds which will be necessary for the purchase of maps, albums, cases, &c., and the defraying of the cost of printing in platinotype, &c., and making lantern slides.

It does not seem unreasonable, however, to ask for subscriptions from all who are interested in such a survey. Our own Society will, it may be hoped, make a grant in aid; and, doubtless, if a portion of the work is done as a sample, and well done, assistance will not be wanting.

The End of a Photographic Survey.—In the way of work to be done there could be no end. Every day sees some change, something of the old order is blotted out, something new is introduced. A railway is made across our pet landscape, and we must photograph the trail of black smoke from the engine, if it be only to send the picture to Mr. Ruskin. How rapidly the features of our towns are changing must be obvious to the most careless observer; and any one who has been absent from the new city for but a few years has good cause to sing the old song, "I can't find Birmingham!"

But the term "end" may also be considered in the sense of "object." What shall be done with our photographs when we get them? Well, this Society should retain at least two complete sets, a working set and one for reference. Complete sets ought also to be prepared for our Municipal Reference Library, for the British Museum, and for any other public institutions who desired a set and were willing to pay for it.

Our schools would value highly a selection of large photographs; and enlargements might be made for this and other special objects, as for exhibition on the walls of our free libraries, for teaching, and for lecturing purposes, &c.

Further, it appears to me that the pursuance of a task such as I have

attempted to sketch out would unite the members of this Society as only men are united who have a definite object in view, and who work for a common end. It would attract, it may be hoped, new workers to join our ranks; and would add to the status of the Society in the eyes of the public. Much energy which is now frittered away would be diverted into a useful channel; and although it may be said that the main benefits of our work will be reaped by a posterity "which has never done anything for us," yet I feel confident that we shall derive as much pleasure from doing the work, as our descendants will from its study and examination.

W. JEROME HARRISON.

A NOVEL MEANS OF REMEDYING CERTAIN DEFECTS IN PORTRAITS.

A VERY clever definition of photography that we once met with in the course of our reading made our art "the art of delineating aspects scientifically." This covers the ground very well; in fact we have never seen anything better. If we take the word "scientifically" in a free and liberal sense here, we might make it refer not only to true and faithful reproductions of objects, but to such scientific delineations of those objects as would tend either to the exaggeration of their beautiful qualities, or to the suppression of their ugly ones.

It is not our purpose to repeat in this connexion any of the unctuous art-jargon concerning "truth in art," &c., which occupies by far too much space in the columns of our photographic literature, but rather to ask our readers to consider the merits of the following curious process, which at first might be regarded in the light of a caricature only.

Transformism, the process alluded to, is defined by M. Ducos du Hauron rather diffusely as follows: "An image, characterised by a change in the relative proportions of the objects represented, is formed if a ray of light be introduced into a dark chamber, not through a simple orifice, but through two slits cut in places which are differently directed, and separated by a proper distance." He then proceeds to give some examples which are startling, to say the least. It seems that when the first of the two slits is vertical and the second (the one nearest the image) horizontal, the image, when compared with the original, will be found to be amplified or stretched vertically. Again, if one of the two slits instead of being rectilinear be curved more or less, the image will show curves or undulations laterally or vertically according to the direction of the slit. The examples therewith given are at least as strange and uncanny as the former ones. All the examples given are portraits, and here is the point that is so surprising—the natural likeness is well preserved in spite of the extreme distortion. The distortion of countenance seen in a convex mirror in some measure approaches to it, but it is not the same.

The method of working adopted by M. du Hauron is quite simple, and we will here give a condensed account of it, premising that for certain unfortunate individuals possessing great facial deformities this process may prove valuable, the photographer having it in his power to greatly exaggerate certain features, and to suppress others. It is this point to which we desire to direct our readers' attention, that the process, called "transformism" for want of any better name, puts into their hands the possibility of altering the features of the sitter, and yet of preserving the likeness while doing so. A sitter with a head so flat and wide as to be unsightly would be a good subject for trial with the first slit vertical and the second horizontal, as we mentioned above. Other examples will suggest themselves. M. du Hauron gives the following directions: "The best means of experimenting with photographic transformism is to provide a dark box so fitted up that twelve or more proofs may be made at one operation. Two partitions or septa are set into a deep frame, opposite to each other and to the sensitive surface at the bottom of the frame, the model being at the other end of the box and well lighted. Each of these two septa is pierced with twelve or more slits, which are brought opposite to each other and disposed in symmetrical rows. Two slits of any given form are then so placed that the desired deformation or distortion may be produced. The model will then be represented by as many different 'transformisms' as there are pairs of slits. In the production of these images the slight distance separating the slits from the sensitive surface will greatly influence the action of the light, so that the exposure will remain within the limits absolutely practicable for portraiture. The proofs obtained will thus all differ the one from the other. A variety may be made by reversing the position of either one, or both, of the two septa above mentioned, turning them upside down, &c. If a camera furnished with a battery of lenses of any desirable number were at hand, a plate of instantaneous proof-types might be made, with the same distances between as between the slits in the septa. This plate could then be set in place before the slitted septa in the dark box, and thus a series of instantaneous portrait transformisms obtained."

It is evident from the above description that the transformism is made from a ready-made portrait or picture, not done direct from the sitter. There are certain points in the process analogous to the pin-hole or diffraction principle of making views. Fun and recreation can be had from the above in plenty; but it is rather as an important means by which defects may be remedied in portraiture that we recommend it to all of our readers who are willing to experiment out of the beaten track.

In concluding, let us add that the making of the slits requires care; they should not be broader than one-third of a millimetre. They should be drawn on white paper with India ink, rather large in size, and with clean edges and borders, then reduced to the desired measure by means of the camera. The negative, of course, must be on glass, and acts as the transforming screen.

ELLERSLIE WALLACE.

Foreign Notes and News.

At the last meeting of the Geneva Photographic Society Professor H. Fol entertained the members present with a dissertation on the resemblance observable between married people. Out of seventy-eight young couples photographed for the purposes of this edifying research, M. Fol found that in twenty-four cases the resemblance between the personal appearance of the spouses was greater than that between brother and sister, in thirty cases equally great, and in twenty-four a total want of any resemblance was perceptible. Note the conclusion arrived at by the learned professor: "In the greater number of instances people choose one another on account of mutual similarity." What would the author of *Wahlverwandtschaften* have said to this? "Tive la Fol-lie!"

PROFESSOR FOL is going to extend his experiments to aged couples, in order to ascertain if there be any tendency for married people to grow like one another. He at present seems inclined to think there is. He will doubtless preface his treatise by allusions to well-known and historical cases of married couples whose mutual resemblance increased with declining years. We shall probably encounter the familiar instances of Darby and Joan, both of whose hair became white after they reached the confines of old age; and John Anderson and his wife (this instance resting on the testimony of a Scotch writer of some celebrity), who both became bald towards the sunset of life. Then he will, perhaps, go on to show that the tendency for the parties to grow like one another is fostered by the intensity of mutual affection, and in confirmation of this view he may point out how the daughters of Gaul manifest a disposition to develop hirsute adornments in their riper years, thus becoming like the opposite sex, for *les belles Françaises* are notoriously affectionate.

DR. MIETHE, in the *Deutsche Photographer Zeitung*, devotes a good deal of space to the ever-interesting question of flash lights. He points out that magnesium powder is often burned in such a way as not to evolve more than an eighth or tenth part of the light which may be obtained when its combustion is effected in a suitably constructed lamp. The reason of this is, according to Dr. Miethe, that the magnesium flame, like so many other brilliant flames, is almost completely opaque, and only gives off light from its surface. If, say, one burns a gramme of magnesium powder in a bunch, so to speak, one will only obtain at best half the illuminating power which the same amount of powder would produce if burned so as to produce a flat flame. The principal object is, therefore, to widen out the flame as much as possible, and so increase the ratio of surface to content. In blowing pure magnesium powder through a flame, care ought also to be taken to prevent any of the magnesium from passing through unburnt, as it is likely to come in contact with plates, albumenised paper, &c., and cause spots.

This explanation, though accounting for a good deal of the observed differences in magnesium lights of the same kind, does not, as Dr. Stolze points out, explain such a difference as 1:10. In flash light compounds the chloride of potash absorbs heat in decomposing, which heat has to be supplied from the combustion of the magnesium powder, thus lowering the temperature of the whole, and as a consequence producing a less intense light. The chloride of potash formed also surrounds the light with a kind of *chromosphere*, which absorbs a good many of the luminous radiations. In the case of lights, such as Dr. Miethe's, where the pure magnesium powder is blown through a Bunsen flame, these causes are not active, and the light is consequently brighter.

THE *Journal de l'Industrie Photographique* recently published two very interesting photographs of the clouds caused by the explosion of the Cartridge Factory at Antwerp, accidentally taken from a distance of 1700 metres. These clouds present a remarkable resemblance to gigantic sponges placed at the top of a column of smoke, and correspond therefore to the phenomena witnessed at volcanic eruptions.

THE Munich Photographic Club is about to publish a free-and-easy sort of periodical under the title *Notiz Blätter des Photo. Clubs*, in

München, to give the members a short account of all the novelties and discoveries in connexion with photography. The above Society has only just recently adopted the *Photographische Correspondenz* as its official organ.

M. KASSELBAUM, in the *Photographische Rundschau*, recommends the following as an intensifier, which is said to act well. The plate is first dipped in a solution of citric acid and then introduced into a bath of the following composition:—

Hydroquinone	6 grammes.
Water	700 "
Nitric acid	10 drops.
Silver nitrate, eight per cent.....	18 c.cm.

It would appear that now even, as in the days of the Revolution, the French still regard everything on the other side of the Rhine as appertaining to Cimmerica and the realm of barbaric darkness and confusion generally! How else can we explain the bland determination with which a French contemporary persists in alluding to the Berlin *Photographische Mittheilungen* as an Austrian journal?

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 19.—Mr. A. L. Henderson in the chair.

Prints from a stereoscopic negative taken by Mr. F. York were shown to illustrate the effect of substituting liquor magnesia carbonate for ammonia and bromide in pyro development. The negative had been divided and one half developed with each mixture, the magnesia half being considered to show the more density and detail.

Mr. J. Traill Taylor showed a covering glass that had been removed from a transparency, and that exhibited an erosion over the whole of the inner surface not in contact with the paper mat. The transparency was one of a set of French production that had been sent to India, the covering glasses of which all exhibited the same defect. Other transparencies of English make that had accompanied them did not suffer from the erosion in question.

Mr. P. EVERETT inquired whether the transparencies had been intensified with mercury, and it being replied that probably they had been so treated, continued, that the mercury had, doubtless, been liberated, and, being condensed upon the glass, had attacked the lead in the glass.

This explanation was generally considered to be the correct one, and the CHAIRMAN mentioned, as lending it additional probability, that he had often noticed the same erosion of the covering glasses of Daguerreotypes where mercury was also employed in the preparation of the photograph.

The CHAIRMAN then brought to the notice of the meeting a stereoscopic slide representing a steamer in middle distance and a shore beyond. The peculiarity about the picture was that, although the negative had been taken with a twin-lens camera exposed with drop shutter, the stereoscopic effect was only properly shown where the print was mounted without the usual transposition.

Mr. TAYLOR, on examining the print, said that the two sides of the picture had been taken not quite simultaneously, and the vessel on which the camera stood having moved forward, the steamer in the picture appeared to cover over a different part of the distance from that in which it was when the first half had been exposed.

Mr. A. COWAN inquired as to the arrangement for exposing the plate, and, finding that there were two separate shutters connected by a loop of string, considered that unless the hand was perfectly central and moved truly one of the shutters would be sure to act slightly before the other.

The Chairman then showed some large instantaneous pictures of animals taken by Mr. F. Radford, of Adelaide, and a number of stereoscopic views by Mr. W. F. Hall, of Sydney. Amongst the latter were some views of the Jerolan Caves, which had been illuminated for the purpose by magnesium lamps.

Mr. TAYLOR thought it a great pity that the latter set of pictures had been spoiled by the name of the subject being printed near the centre of the scene.

The CHAIRMAN thought so too, and hoped that these observations would be reported and reach the producer of the pictures, and that he would be induced to forego the practice.

Mr. J. B. B. Wellington showed a negative which in the sky exhibited traces of an image belonging to another negative. The plate exhibited had been lying for some time undeveloped, with a piece of tissue paper separating it from a plate that had been developed, and fixed, and slightly washed before drying. It was the image of this negative that had been impressed upon the plate now shown.

Mr. W. E. DEBENHAM suggested, as a possible explanation, that the plates

had been exposed for some time to the light in the dark room or elsewhere with the developed negative uppermost.

The CHAIRMAN thought it more probable that there was some relief in the developed negative, and that this relief had acted through the tissue paper, producing the effect known as shearing stress.

Mr. Cowan showed the "Norsen" vignetting arrangement, a contrivance which admitted of great variation of effect and of constancy when the particular effect desired had been decided upon.

CAMERA CLUB.

ON Thursday, December 19, Mr. LYONEL CLARK read a paper upon *Salting and Exciting Ordinary Drawing Paper for Silver Printing*. The paper was accompanied by a demonstration. Mr. W. Clarke occupied the chair.

Previous to the lecture the Secretary handed round some excellent paper negatives made in 1853 by Mr. Registrar Jackson, of the Law Courts, and lent by Mr. Gambier Bolton, also some enlargements on celluloid ivory films lent by Messrs. Fry & Co. for exhibition.

Mr. CLARK described the qualities and characteristics of the different rough papers employed, and specified the particular treatment required for each. After giving details of the salting and exciting, he proceeded to show the processes, floating the paper upon the salting and sizing solution (a thick gelatine sizing being required for the rough, stout papers). After drying, he sensitised the sheets, employing a brush which was a modification of the Blanchard brush, swansdown calico being folded over a ten-inch sheet of celluloid bent till the two edges met, and the whole held by wooden clip handle after the manner of a squeegee. This brush was pliant and yet firm. In sensitising, Mr. Clark stated that Mr. Burton suggested twice sensitising; he himself found once sufficient. The difference in opinion was due, no doubt, to the fact that Mr. Burton soaked his paper in salting, whereas he (Mr. Clark) only floated it and used a strong sizing. Mr. Burton's method would appear to require more silver salt in exciting. Mr. Clark also exhibited a large number of examples and demonstrated several methods of toning and intensifying prints, the silver intensifier serving to bring up to full strength prints very faintly printed.

In the discussion, Messrs. Anstn, Shipton, Davison, Maskell, Dr. Patterson, and the Chairman took part.

Thursday, January 2, will be a lantern evening.

NORTH LONDON PHOTOGRAPHIC SOCIETY

DECEMBER 17.—The President (Mr. J. Traill Taylor) in the chair

Mr. H. Hudson was elected to membership.

Mr. W. H. SMITH, of the Platinotype Company, showed and explained the working of a new hand camera now being placed on the market by that Company. It could not in any sense be called a detective camera, as its appearance would at once betray its purpose, but the ingenuity of its construction was allowed by all, and the perfection of the workmanship was much admired.

Mr. SMITH then proceeded to explain and demonstrate *The Hot Bath Process of Platinotype Printing*. He said the process of preparing the paper was attended with too many difficulties to make it worth while to attempt it in small quantities; it was, therefore, recommended that it be purchased ready prepared. The only condition with regard to the sensitised paper which it was necessary to observe was that it should be kept perfectly dry, otherwise the prints would suffer in quality, and, instead of being brilliant, would be flat and without vigour. The paper should, therefore, be stored in a calcium tube, which consisted of a tin case having a receptacle for chloride of calcium, and, when placed in the printing frame, it should be backed up with a sheet of thin indiarubber or mackintosh cloth. In the printing, although the paper did not print out, a faint image was formed, which was sufficient to indicate, after a little practice, when the exposure had been sufficiently prolonged. The demonstrator then passed round a number of exposed prints and replied to several questions from members relating to the exposure they had received, &c. He then proceeded to develop these prints in the following manner, explaining each step as he proceeded:—A quantity of the developing solution, consisting of one pound of oxalate of potash dissolved in fifty-four ounces of water, was placed in an enamelled iron dish and heated, by means of a Bunsen gas burner, to a temperature of 160°. A print was then floated on the surface of the solution for a few seconds, until the developing action was complete; when this occurred the print was removed directly into a bath of hydrochloric acid solution—about one part acid to sixty of water—and there left immersed for about ten minutes, after which time it was removed to a second similar bath, and then to a third, in each of which it remained the same time; a thorough washing in water completed the operations. Mr. Smith explained that some degree of modification was admissible in the temperature of the developing bath, which could be used cooler, but he thought it advisable not to use it at a lower temperature than 130°. It was certainly easier to use at the higher temperature. The function of the acid baths was to remove the iron salts from the paper, and if the third bath was in the least degree discoloured another bath should be given to the prints. A large number of prints from negatives which had been supplied for the purpose by various members were developed.

Mr. N. P. FOX said he had used the bath at a much lower temperature than that recommended with success.

Mr. A. MACKIE said the platinotype process was one of the many processes based upon that discovery by Sir John Herschel, that some of the per-salts were reduced by the action of light to proto-salts, which proto-salts have the power of reducing some of the metals from certain of their salts. In the present instance the per-salt employed is ferric oxalate, a solution of which mixed with a solution of potassic platinous chloride is spread on paper and dried. The action of printing is to convert that part of the ferric oxalate which has been exposed to light to ferrous oxalate. The ferrous oxalate is capable of reducing the platinum from the platinous salt if brought into intimate contact with it, but is incapable of acting to any extent in the dry state. The required contact is attained by the action of the potassium oxalate solution, in which the ferrous oxalate dissolves and at the moment of solution reduces the platinum.

A vote of thanks having been passed to Mr. Smith, the CHAIRMAN announced that Mr. N. P. Fox had found it necessary to resign his office as Secretary, and that the duties of that office had been kindly undertaken for the present by Mr. G. J. Clark, of 52, Queen's-road, Brownwood Park, N., to whom all communications for the Society should be addressed.

The next meeting will be held on Tuesday, January 7, and will be a lantern night.

BATH PHOTOGRAPHIC SOCIETY.

DECEMBER 18.—Ordinary meeting at the Royal Literary and Scientific Institute, Terrace Walks.

Communications received were dealt with and forthcoming meetings announced:—January 8, Special evening devoted to Flash-light Apparatus and Photography. Open to all interested, at Messrs. Powell's Rooms, 10, Quiet-street. Visitors invited to bring cameras and lamps. January 29, Lantern night at the Institution, when Mr. Dugdale will illustrate scenes visited by the Society during the past season.—February 26, Annual meeting, when Mr. Friese Greene will exhibit his new camera and pictures taken by it.

Mr. Dugdale showed examples of silver printing of an effective character.

The PRESIDENT then gave an extremely interesting lecture upon *The Chief Subjects for the Camera to be found in the Cities of Italy*. The lecture was illustrated with eighty-six wet collodion transparencies from film negatives made by the President in Milan, Venice, Genoa, Rome, Florence, &c. The lecture also teemed with historical information and many amusing anecdotes.

Mr. AUSTIN J. KING moved the vote of thanks, after which several questions were asked and answered concerning lens, camera, and film used, and the method of toning the transparencies.

BRIGHTON PHOTOGRAPHIC SOCIETY.

DECEMBER 10.—Messrs. WEBLING and CORDER gave an account of their holiday in North Wales, illustrated by about ninety pictures shown by means of the oxyhydrogen lantern, the accompanying description being given by Mr. Webbling.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

DECEMBER 12.—Dr. J. K. Tulloch (President) in the chair.

Mr. W. D. VALENTINE, Judge in the lantern slide competition, awarded the prizes as follows:—1, Mr. H. S. Wybrants; 2, Mr. W. Salmon; and 3, Mr. J. Mathewson. His report stated that nearly all the slides were of very superior quality, and much above the average of such work. This competition was principally for technical excellence. Three negatives were selected by the Council, from which slides had to be made by each competitor.

A number of slides by members of the Society and of the Paisley Society were exhibited by the limelight.

Messrs. Mawson & Swan exhibited one of their transparency frames.

PACIFIC COAST AMATEUR PHOTOGRAPHIC ASSOCIATION.

At a special meeting, called for the purpose, on November 21, Mr. H. S. BELLSMITH, of the Eastman Company, appeared before the Association to describe the manufacture of the new film and the subsequent manipulations necessary to produce a negative. As this was the third appearance of Mr. Bellsmith before the members, he was given a right cordial greeting by a meeting fully as large as has ever assembled in the rooms of the Association.

With his direct style, good voice, and easy manner, he closely held their attention while he described the events which led to the gradual development from the first film produced by the Company, which was on paper, and had to be oiled, to the transparent film of to-day, which is ready for printing as soon as dry after development. The difficulties and objections to the disagreeable work of oiling were humorously spoken of, and now that they are upon the verge of the past, Mr. Bellsmith confessed that there was an awful lot of work connected with stripping. As the process of manufacture of the films used in the stripping process is known to readers of magazines, the description given, though interesting, will not be here repeated. Some facts regarding the new film, however, are interesting. At first it was thought impossible to make a celluloid support long enough for use in the roll holder. After the difficulties to the way had been overcome, there was trouble in getting the celluloid thin enough, for when too thick it would not lay flat on the table of the roll holder. After this question had been solved it was found that the emulsion separated from its support, sometimes even before reaching the developer—what is known as dry frill. This was caused by the celluloid not being sufficiently seasoned, the presence of camphor, which is largely used in all forms of celluloid, preventing the necessary adherence. Finally this serious difficulty was overcome, and its removal allows the production of the most satisfactory substitute for glass yet discovered.

Having finished his description, Mr. Bellsmith had the lights turned down, and, with the aid of proper illumination, proceeded to develop some exposures. Six pieces of transparent film were soaked in water to make them lay flat, and afterwards transferred, one at a time, to a diluted developing solution of elikonogen. They were kept in motion, examined frequently, and, in a remarkably short time—about twenty minutes—so dry longer than the time required to develop a plate, six good negatives were produced. To guard against their frilling, made possible by the heat of the hand tending to dissolve the substratum, they were passed through an alum bath before fixing. After the hypo they were washed in the usual manner and then soaked in a solution of glycerine and water to ensure their laying quite flat. Before the final washing they were handled around among the members for examination, and found to equal products on glass. Judging by sample negatives and prints, the results are much finer than those obtained by the stripping process, aside from the fact that negatives are easier to make. The skies are perfectly even, without the slightest trace of grain or mottle.

After this successful demonstration, Mr. Bellsmith exhibited a number of

new cameras, also the first Kodak ever made. Upon this subject the older members, as seasoned veterans of the tripod, could not resist the temptation to "josh" him upon the subject of "You push the button, we do the rest;" but he ably retorted, and, by the production of the most compact and complete detective or hand camera yet seen here, changed their criticisms to admiration. First came the enlarged Kodak. "No longer a Kodak," said the critics, for it contained a finder and a changeable focus. The size of the image, still circular in form, is about double that of the first Kodak. The size of the box is about that of the ordinary detective. Good as this camera is, it cannot hold a candle to its companion, the folding hand or detective camera. The front of this box drops down and is held in place by two braces. A bellows with lens and shutter attached is drawn out to a registered mark and fastened by the turn of a lever; the shutter is set, the exposure made, and the box closed up all in a moment. Equipped with a roll holder carrying transparent films sufficient for forty-eight exposures, this camera is complete, and must become a favourite, particularly if it is furnished with a ground glass, as some of the members suggested. Upon the 5x7 an ingenious arrangement of the rising front permits more sky to be obtained when used either horizontally or vertically, and the finder also changes to suit the shape to be made.

Correspondence.

Correspondents should never write on both sides of the paper.

AMATEUR VERSUS PROFESSIONAL.

To the Editor.

SIR,—Having read several of the letters on the above subject which have appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY, may I humbly suggest that in continuing the discussion the "versus" be henceforth omitted, for I see no earthly reason why each should not pursue his own course as he pleases without interfering with the other. As a professional photographer I am always pleased to meet an amateur. I do not mean a Shamateur—this latter class I do not think anybody, be he amateur or professional, has the slightest respect for, but even what he does cuts two ways; he produces photographic atrocities of his friends and charges cost of material, plus a little for time, &c. Now, although this tends to bring photography into disrepute as being cheap and easy (Mr. Shamateur has only had a camera so many weeks, they quote), yet when they see these atrocities side by side with the work done in a properly constructed studio by skillful men, they feel somewhat ashamed of the badly finished caricature (although it was cheap), and go to the nearest professional and obtain a good portrait, with the result that the cheap and nasty ones get burnt or hidden away, and photography goes up in their estimation as not being so easy after all.

As to the suggestion of a Trade Union, personally I look upon that as somewhat degrading, whilst a tax on every one who carries a camera would be very hard indeed, and almost as unjust as would be an attempt to tax every one who takes a trip into the country to enjoy the fresh air and change of scene in order that the doctors might have more business. The idea that amateur competition has reduced prices is only true to a very small degree. The cutting down of prices has emanated from within the profession, and not from without, as many seem to think. It is the rivalry amongst ourselves and the general badness of the times that is to blame for most of the trouble, and not the amateur, for, as most of us know who look at the question dispassionately, more than nine-tenths of the work he does would remain undone unless he did it, whilst a great deal of his work is a source of profit to the local photographer in after-manipulations, such as printing, &c.

It would be impossible to touch on the many causes that have helped to lower prices, but there is one that many photographers in provincial towns have suffered from, namely, that they engage a man as assistant operator, he remains a year or two, gains experience, and saves or has enough to buy a camera, lens, and a few accessories; then sets up in opposition to his late employer, whose clients and methods of doing business being well known to him make him at once a dangerous rival, particularly as, in order to attract business, he usually starts by fixing prices somewhat lower than his late employer's, this frequently ending in alternate reductions of prices until there is no margin of profit left. As a remedy for this evil I should suggest a clause in agreements, that an employé should not start in business for himself within a given radius, unless under a heavy fine. This may sound harsh, but it is the usual custom in several other businesses.

If a tax must be levied on photography, I would suggest that it should be applied only to work actually sold; it might take the form of a Government adhesive stamp to be affixed to each photographic print making it illegal under heavy penalties to buy or sell photographs without so stamped. This would at any rate cut against the pseudo-amateur, whilst it would not in any way interfere with the true amateur who photographs for the pure love of the thing.—I am, yours, &c.,

RED PINE.

ROBINSON AT THE CAMERA CLUB.

To the Editor.

SIR,—Should any of your readers care to judge for themselves whether my letter (which appeared in your issue of the 8th of November) was

written in an offensive spirit or manner, I ask them to do me the justice to refer to it.

I decline to enter into any correspondence with a man who writes in such an intemperate manner as Mr. Robinson has done of one who never said an unkind word to or of him.—I am, yours, &c., BART ROUS.

The Arts Club.

[Here this matter terminates.—Ed.]

CELLULOID FILMS FOR LANTERN SLIDES.

To the Editor.

SIR,—The two gentlemen who write with reference to my article on the above subject which appeared in your issue of December 13th, appear to me to contradict one another. Mr. England says that celluloid is of no use for lantern slides; while Mr. Adams tells us that he has patented its use for that purpose!

If Mr. England will kindly read my article again, he will see that I show how the greater part of the heat-rays can—if necessary—be filtered out. But Mr. England must remember that in my experiments I have used only the thick, yet very rigid and transparent films, so beautifully made and coated by Mr. Fitch. I believe that celluloid films were prepared by Mr. Fitch even before the American workers, who are generally credited with its first application—in a transparent form—to photography.

It is probable that few exhibitors of lantern slides will require to keep their celluloid films for more than one or two minutes in the lantern. Any "buckling" can be prevented by putting the film between a couple of pieces of thin glass before inserting it in its holder. A tank of alum-water just in front of the condenser will filter out most of the heat-rays without practically impairing the light.—I am, yours, &c.,

W. JEROME HARRISON.

Science Laboratory, Icknield Street, Birmingham.

Exchange Column.

I will exchange *Cassell's Illustrated Shakespeare*, complete, unbound, and quantity of lantern plates and lantern slides of Irish scenery, for a pair of condensers and porcelain developing dishes.—Address, W., 30, Vicarage-road, Willesden.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2 York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHY.—REGISTERED:—

R. G. M., Market Drayton.—Two photographs of J. Taylor, Esq., High Sheriff of Shropshire.

E. M.—No such Directory is published.

J. L., referring to a lamp mentioned in the ALMANAC, the "Vulcan Safety," asks where this can be obtained, as he should like to try one.

H. M. W.—We do not know anything concerning the Chicago "Turn Over" detective camera, but will look up our American exchanges for information.

COPY.—Messrs. Mawson & Swan still continue to supply collodion for the wet process. Apply to them direct. Many dealers do not keep it in stock now.

A. F. TYLER.—Considerable advantage may accrue from the use of orthochromatised plates in the studio when the light is yellow from foginess of the weather. The formula named gives excellent results.

S. GOODR.—The best and cheapest process by which to illustrate the book is the colotype. For so small an edition no other process will prove so cheap. The prints can be produced with a clean margin, so that no mounting is required.

F. N. F.—There being no statement as to diameter and focus of your lens, we cannot say whether it would enlarge a half-plate negative. It seems to us that it would answer well enough for a quarter-plate, but why not ascertain this by actual trial?

W. C. B.—Enamelling collodion may be made by dissolving four grains of pyroxyline and four drops of castor oil in half an ounce of ether and half an ounce of strong methylated spirit. For directions to use it see page 477 of our ALMANAC for 1888.

C. BOLING.—Gum is a very good mountant for photographs, provided it contains nothing that will act injuriously on the picture. This, however, is the case with the glues of commerce, as they are generally acid, and contain other impurities.

A. B.—The class of portrait lenses usually designated "B" possess a much larger aperture than the rapid rectilinear, and therefore work more rapidly. This is a general statement only, as some "B's" may be slower than some rectilinears may be abnormally rapid.

W. B. WOOD.—The cabinet lens does not answer in its entirety because of the focus of the nine-inch diameter double convex being too long. This would be rectified by the addition of a nine-inch plano-convex, flat side placed next the lights, but the best way would be to get proper condensers the correct size.

F. GUTENST (Philadelphia).—The paper in question is what is known as *papier minéral*. It may doubtless be obtained from Messrs. Anthony & Co., of New York. They used to be the agents for Lambertype materials. It may also be had from Messrs. Marion & Co., London, and other stock dealers.

W. A. J.—For photographing such objects as those mentioned an objective of three inches focus should be used. No success must be expected if a deeper power be employed. A long exposure will be necessary, on account of the non-actinic character of the objects, if the source of light is an ordinary paraffin lamp. The limelight will be far better if it be available.

SIGMA inquires how to obtain good black-and-white negatives of engravings.

He says he wants the lines perfectly clear and the other parts very dense.—The best process for this class of work is wet collodion, but very good results may be obtained on ordinary slow plates with careful development. Perhaps the best commercial plates for the work are those specially prepared for the purpose, and sold by Mawson & Swan under the name of "photo-mechanical" plates. They are slow and yield results very similar to those obtained on wet collodion.

SYDNEY TELBUTT writes: "Your issue of August 3, 1888, gives an account of a discussion on stereoscopic matters at the Photographic Convention of the United Kingdom. It is there twice mentioned about 'Wheatstone's' stereoscope and once about an instrument for this same purpose invented by Sir Howard Grubb. I would be much obliged to you if you could put me in the way of obtaining either or both such instruments."—With respect to the former we cannot say where a Wheatstone stereoscope can now be obtained; but a letter addressed to Sir Howard Grubb, Dublin, would ensure information as to the latter.

H. A. HUTCHINSON asks: "1. Is a coating of varnish sufficient to resist hypo on wood? I am making a fixing tank for negatives as I have seen suggested in your columns, the ends and bottom of wood, the sides of glass, but I don't know whether the varnish would stand.—2. Do you think the extra price (about fifty per cent.) of thickly coated landscape plates over, say, Ilford or Fry's ordinary, is good value? I have asked several of my friends who are old hands at photography, but their opinions vary so.—3. My negatives (half-plates) are taken half for enlarging on bromide paper and half for matt-surface silver prints or platinotypes, so I am in doubt which of the two classes of negatives would be best for both kinds of work."—In reply: 1. Yes, if the varnish be impervious. Several coats of shellac will answer, but better still is a good coating of paraffin wax.—2. Yes, for some purposes. Why not compare results for yourself?—3. For printing in platinum, negatives of a more vigorous character are required than for enlarging on bromide paper.

ARTIST writes: "Will you kindly answer the following question in correspondence? Having been engaged by a country firm on a salary of 2l. 2s. per week for under three months was compelled to sign an agreement not to work for any other photographer in same town or within twenty miles radius for two years after leaving, under a penalty of 20l., or to take any kind of photograph on his own account in the same town. The agreement stated a week's notice on either side in writing; only a verbal notice was given, no writing whatever. Does the agreement stand good? There was no money given as a bonus to bind the agreement."—This is purely a legal question, and one we cannot answer with any degree of confidence. We fully imagine that in a court of law the prohibition to follow one's business a radius twenty miles would be ruled as an "undue restriction of trade." Furthermore, that the agreement was not an equitable one, inasmuch as no consideration was given which would make it binding. Also it was ignored by the employer in terminating the service of the employee. This is our opinion; and we give it for what it is worth. Perhaps some of our legal friends will supplement it with their opinions.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday December 31, at 5a, Pall Mall East, at eight p.m.

PHOTOGRAPHIC CLUB.—Wednesday, January 1, monthly lantern meeting (instead of December 25). Subject for discussion, *Lantern Matters*.

BIRMINGHAM PHOTOGRAPHIC SOCIETY EXHIBITION.—Our readers are reminded that all pictures intended for this Exhibition must be forwarded so as to be received not later than January 7, 1889, addressed to Mr. J. H. Pickard, 39 and 40, Woodcock-street, Birmingham.

ROYTON EXHIBITION.—The time for receiving pictures for this Exhibition has been extended to January 15.

THE PHOTOGRAPHIC CLUB.—Presentation.—The annual dinner took place at Anderton's Hotel, on Wednesday, December 18. Mr. W. Ackland presided and Mr. T. Charters White occupied the vice-chair. During the evening a testimonial was presented to Mr. Edward Dunmore, the late Hon. Secretary and Treasurer. It consisted of a gold watch, and the "Life Membership" of the Club, illuminated on vellum and handsomely framed. There was a large attendance of Members, and a most enjoyable evening was spent. Songs, pianoforte solos, and recitations being contributed by Messrs. A. Cowan, J. W. Kippis, W. Holt, Tagliaferro, Charters White, Scrivener, F. A. Bridge, &c.
